INTRODUCTION

TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

THE names used to denote ring formulae are given below for convenience of reference.

Since the publication of the last volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs. T. Cooksey, T. A. Lawson, Samuel Rideal, Messrs. J. Wilkie, G. N. Huntly, J. T. Norman, and D. A. Louis. I have also been assisted by Mr. Arthur G. Graef and Mr. Cecil W. Cunningham in the work of revising the proof-sheets. I have great pleasure in thanking these gentlemen for the energetic and efficient manner in which they have carried out their share of the work.

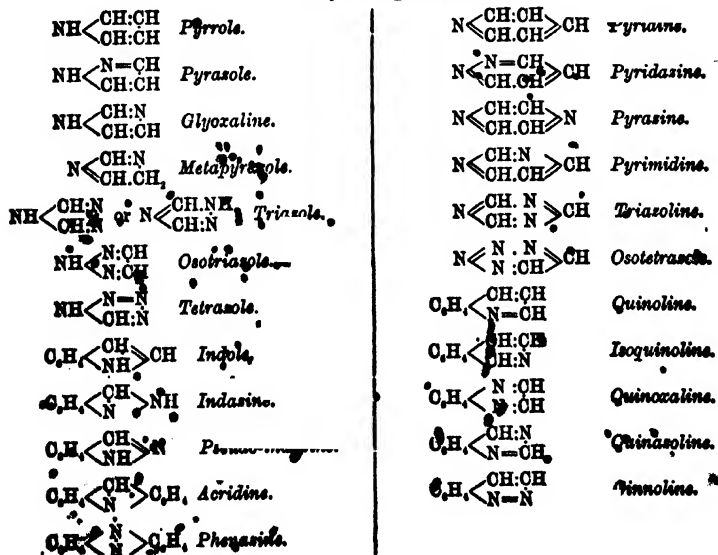

H. FORSTER MORLEY.

Nomenclature of Ring Formulae.

Sulphur compounds.

INITIALS OF SPECIAL CONTRIBUTORS.

H. E. A.	H. E. ARMSTRONG, Ph.D., F.R.S., <i>Professor of Chemistry in the City and Guilds Central Institution.</i> Contributes ISOMERISM.
D. C.	DOUGLAS CARNEGIE, Esq., M.A., <i>formerly Demonstrator in Chemistry, Gonville and Caius College, Cambridge.</i> Contributes PERIODIC LAW.
W. C.	WILLIAM CROOKES, Esq., F.R.S. Contributes METALS, RARE.
C. F. C.	C. F. CROSS, Esq., <i>Consulting Chemist.</i> Contributes LIGNONE.
L. F.	L. FLETCHER, M.A., F.R.S., <i>Keeper of the Mineralogical Department, British Museum.</i> Contributes MINERALOGICAL CHEMISTRY.
W. D. H.	W. D. HALLIBURTON, M.D., B.Sc., F.R.S., <i>Professor of Physiology at King's College, London.</i> Contributes MILK and MUSCLE.
A. K. H.	A. K. HUNTINGTON, Ph.D., <i>Professor of Metallurgy, King's College, London.</i> Contributes METALLURGICAL CHEMISTRY.
A. H.	ARTHUR HUTCHINSON, M.A., Ph.D., <i>Demonstrator in Chemistry, Gonville and Caius College, Cambridge.</i> Contributes ISOMORPHISM.
F. R. J.	FRANCIS R. JAPP, M.A., Ph.D., F.R.S., <i>Professor of Chemistry in the University of Aberdeen.</i> Contributes KETONES and LIPIDEN.
S. R.	SAMUEL RIDGEMAN, D.Sc., <i>Lecturer on Chemistry at St. George's Hospital Medical School.</i> Contributes PARAFFIN and PETROLEUM.
W. A. S.	W. A. SHENSTONE, Esq., <i>Lecturer in Chemistry at Clifton College.</i> Contributes OZONE.
W. A. T.	WILLIAM A. TILDEN, D.Sc., F.R.S., <i>Professor of Chemistry at Mason College, Birmingham.</i> Contributes PENTINENE.
J. J. T.	J. J. THOMSON, M.A., F.R.S., <i>Professor of Experimental Physics in the University of Cambridge.</i> Contributes MOLECULAR CONSTITUTION OF BODIES, THEORIES OF.

Articles by Mr. MUIR are initialed M. M. P. M.

UNIONPAP ARTICLES are by Dr. MORLEY.

II. TERMS AND QUANTITIES, &c., FREQUENTLY USED.

Aq.	Water; e.g. NaOHaq means an aqueous solution of caustic soda.
aq.	18 parts by weight of water.
A'	Residues of mono-, di-, and tri-basic acids. Thus, in describing the salts of a monobasic acid NaA', CaA', AlA', may be written, HA ₃ standing for the acid. For a dibasic acid we should write Na ₂ A'', CaA'', Al ₂ A'', &c.
A''' etc.	Stand for bases of the ammonia type, in describing their salts. Thus the hydrochloride would be B'HCl or B''HCl, according as the base is monacid or diacid, &c.
conc.	Concentrated.
dil.	Dilute.
g.	gram.
mgm.	milligram.
mm.	millimetre.
mol.	molecule.
oil.	liquid, nearly, or quite, insoluble in water.
pp.	precipitate.
to ppt.	to precipitate.
ppg.	precipitating.
ppd.	precipitated.

ABBREVIATIONS

sol.		soluble in.
insol.		insoluble in.
v. e. sol.		very easily
v. sol.		very
m. sol.		moderately
sl. sol.		slightly
v. sl. sol.		very slightly
v.		see.
cf.		compare.
c.		about.
[m]		a melting-point.
[b]		a boiling-point.
H.		Hardness (of minerals).
At. w.		Atomic weight.
Mol. w. or M. w.		Molecular weight.
D.		Density.
cor.		corrected.
uncor.		uncorrected.
v.		in vapour.
v.D.		vapour-density, i.e. density of gas compared with hydrogen or air
S.G.		Specific gravity compared with water.
L.G. ^{16°}		" " at 16° compared with water at 60°.
L.G. ^{15°}		" " " 15° " " " 4°.
S.G. ^{12°}		" " " 12°; compared with water of which the temperature is not given.
S.H.		Specific heat.
S.H. v.		" " of a gas at constant volume.
S.H. p.		" " " pressure.
H.C.v.		Quantity of heat, in gram-units, produced during the complete combustion of the mass of a solid or liquid body represented by its formula, taken in grams.
H.C. v.		Heat of combustion in gram-units of a gram-molecule of an element or compound, when gaseous, under constant volume.
H.C. p.		The same, under constant pressure.
H.F.		Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formulae, taken in grams.
F.F. v.		Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume.
F.F. p.		The same, under constant pressure.
H.V.		Heat of vaporisation of a liquid, i.e. gram-units of heat required to change a gram-molecule of the liquid compound at B. P. into gas at same temperature and pressure.
T.C.		Thermal conductivity (unit to be stated).
S.V.		Specific volume; or the molecular weight of a gaseous compound divided by the S.G. of the liquid compound at its boiling-point compared with water at 4°.
S _g /S.		Specific volume of a solid; or the mass of the solid expressed by its formula, taken in grams, divided by its S.G.
E.C.		Electrical conductivity (the unit is stated in each case).
C.E. (10° to 20°)		Coefficient of expansion (between 10° and 20°).
S.		Solubility in water of a gas = volume dissolved by 1 volume of water.
S. (alco- hol)		" " alcohol " 100 grms. of water. In both cases the temperature is stated.
n _D , &c.		Index of refraction for sodium light D, &c.
R _D %		"Molecular refraction for sodium light, i.e. index of refraction for line D minus one, multiplied by molecular weight, and divided by S.G. at 15° compared with water at 0°.
R _p .		The same; S.G. being determined at 15°-20° and referred to water at 4°.
R _∞ .		The same for line of infinite wave-length, index being determined by Cauchy's formula (Brühl's R _λ).
(α) _D		Specific rotation for sodium light.
(α)		" " neutral tint. [α] = 100 α - observed rotation for 100 min. of liquid. d = S.G. of liquid. p = no. of grammes of active substance in 100 grammes of liquid.

M. M.	Molecular magnetic rotatory power = $\frac{m}{d \cdot a \cdot m}$, where m = molecular weight of the body of S.G. = d , a = angle of rotation under magnetic influence, a' = angle of rotation of water under same influence, and m' = molecular weight of water (18).
Ac	Acetyl C ₂ H ₃ O.
Bz	Benzoyl C ₆ H ₅ O.
Cy	Cyanogen CN.
Et	Ethyl C ₂ H ₅ .
Me	Methyl CH ₃ .
Ph	Phenyl C ₆ H ₅ .
Pr	Normal Propyl CH ₂ . CH ₂ . CH ₃ .
Pr	Isopropyl CH(CH ₃) ₂ .
R, R &c.	Alcohol radicals or alkyls.
prim	primary.
sec	secondary.
tert	tertiary.
n	normal.
m, o, p	meta—ortho—para.
c	consecutive.
i	irregular.
s	symmetrical.
u	unsymmetrical.
ψ	pseudo.
N	attached to nitrogen.
a	Employed to denote that the substituent is attached to a carbon atom which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined by the nature of the compound. Thus CH ₃ CHBr.CO ₂ H is α-bromopropionic acid.
β	denotes that the element or radicle which follows it is attached to a terminal carbon atom.
γ	indicate position in an open chain, only.
1, 2, 3, &c.	indicate position in a ring only.
(α), (β), &c.	Used when α, β, &c. are employed in a sense different from the above, e.g. (α)-di-bromo-camphor.
(B.)	Baeyer's Nomenclature:
(Py.)	benzene ring.
	pyridine ring.
	Thus (B. 1:3) dichloroquinoline, means a meta-dichloroquinoline in which the chlorine atoms are both in the benzene ring.
	While (Py. 1:3) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings, but both united to the same carbon atom.
(4.)	denotes the central ring in the molecule of anthracene, acridines, and azines.
exo	meant that the element or radicle it precedes is in a closed ring.
endo	not in a benzene ring.
allo	denotes "isomerism" that is not indicated by ordinary formulæ; thus maleic acid may be called <i>allo</i> -fumaric acid.
thio	denotes displacement of oxygen by sulphur.
sulpho	" the group SO ₂ H, except in the word sulphocyanide.
sulphydro	" the group SH.
	*Tribromonitrobenzene sulphonic acid [1:2:3:5] means that the three bromines occupy positions 1, 2, and 3; the nitro-group the position 4, and the sulpho-group the position 5.

* Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulae without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave-lengths are given in 10⁻⁷ m.

Formulae, when used instead of names of substances, have a qualitative meaning only.

Thomson's notation is used in thermochemical data.

DICTIONARY OF CHEMISTRY

INDIGO-CARBOXYLIC ACID v. **INDIGO**?

INDIGO-CARMINE v. **INDIGO**.

INDIGO-SULPHONIC ACID v. **INDIGO**.

INDIGOTINE v. **INDIGO**.

INDIGO-WHITE v. **INDIGO**.

INDULEUCINE v. **INDIGO**.

INDIN $C_{12}H_8N_2O_2$. Formed by the action of potash upon isatyde, thio-isatyde, or di-thio-isatyde; formed also by heating isatan (Laurent, *A. Ch.* [3] 5, 471). Obtained also by boiling a solution of dioxindole in glycerin for a long time (Knop, *Z.* 1865, 278). Deep rose-coloured powder or minute needles. Insol. water, v. sl. sol. alcohol and ether. Dissolves in H_2SO_4 , forming a red solution, whence it is pptd. unchanged by water. A solution in concentrated alcoholic KOH deposits black crystals, apparently either $C_{12}H_8KN_2O_2$ or, more probably, potassium indate $C_{12}H_8KN_2O_2$.

Di-bromo-indin $C_{12}H_6Br_2N_2O_2$. Formed by the action of bromine on indin or on di-thio-isatyde (Laurent). Formed also by heating di-bromo-isatyde at 220° (Erdmann, *J. pr.* 22, 265). Yellow-black powder, sl. sol. alcohol.

Di-chloro-indin $C_{12}H_6Cl_2N_2O_2$. Obtained by heating di-chloro-isatyde either alone or with alcoholic potash (E.). Dirty-violet powder; insol. water, alcohol, and HCl aq. Forms a yellowish solution in KOH aq. from which HCl ppts. yellow flakes.

Tetra-chloro-indin $C_{12}H_4Cl_4N_2O_2$. Formed by heating di-chloro-isatyde either with alcoholic potash or alone below 200° (E.). Dirty-violet powder.

Di-nitro-indin $C_{12}H_6(NO_2)_2N_2O_2$. Formed by boiling indin or hydrindin with HNO_3 (L.). Bright-violet powder, insol. water, v. sl. sol. alcohol and ether. Forms a dark-brown solution in KOH aq.

Indin di-sulphonic acid $C_{12}H_6(SO_3H)_2N_2O_2$. Formed by oxidising hydrindin di-sulphonic acid with HNO_3 , with FeO_3 , with $NaOCl$, or even by exposing it in alkaline solution to the air (G. a. A. Schlieper, *A.* 120, 24). Red deliquescent crystals, v. sol. water, sl. sol. alcohol, insol. ether. Its solution dyes silk and wool scarlet. Ammonium sulphide reduces it to hydrindin di-sulphonic acid. It forms a purple solution in KOH aq., and on warming the solution it becomes pale red, probably through assimilation of water. On adding HCl to the pale-red solution a yellow pp. is formed ($C_{12}H_8(SO_3H)_2N_2O_2$), which, when heated, quickly changes to indin di-sulphonic acid. Salts.— K, A' 5aq: lustrous red needles. — Ag, A' : bulky brown needles.— BaA'' 2aq: slender dark reddish-brown needles or crimson

Yos. III.

powder. M. sol. water, insol. $BaCl_2$ aq., alcohol and cold HCl aq.

Hydrindin $C_{12}H_{10}N_2O_2$? Formed by the action of alcoholic potash upon indin, isatyde thio-isatyde, or di-thio-isatyde (Laurent, *A. Ch.* [3] 3, 475). White, or pale-yellow powder or needles (from alcohol), insol. water, sl. sol. boiling alcohol. Boiling HNO_3 converts it into a violet powder. Hydrindin dissolves in warm aqueous KOH, and on cooling there separate pale-yellow needles of a salt $C_{12}H_{12}KN_2O_2$ 8aq, which is decomposed by washing with water, leaving hydrindin.

Hydrindin disulphonic acid, so called, $C_{12}H_8(SO_3H)_2N_2O_2$? Formed by the action of ammonium sulphide on indin sulphonic acid or on isatin sulphonic acid (G. a. A. Schlieper, *A.* 120, 20). Colourless radio-crystalline mass, which becomes reddish when exposed to air. V. e. sol. water, m. sol. alcohol, insol. ether. In alkaline solution it is oxidised by air to indin sulphonic acid.— BaA'' 4aq: white scales, v. sol. water, v. sl. sol. $BaCl_2$ aq.

Leucindin disulphonic acid $C_{12}H_{10}(SO_3H)_2N_2O_2$? Formed by boiling the preceding with baryta-water (G. a. A. Schlieper, *A.* 120, 38). White crystalline mass, v. sol. water, sl. sol. alcohol. Not reddened by the action of air on its alkaline solutions. On evaporating with HCl aq. there is formed indin disulphonic acid.— BaA'' 5aq: colourless crystals. Its solution is not pptd. by $AgNO_3$, till NH_4Aq is added.

INDIPURPURIN is identical with *Indirubin* v. **INDIGO**.

INDIRETIN v. **INDIGO**.

INDIRUBIN v. **INDIGO**.

INDIUM. In. At. w. 118.4. Mol. w. unknown, as V.D. of element has not yet been determined. [176°] (Winkler, *J. pr.* 102, 278). S.G. 7.11 to 7.147 (Reich a. Richter, *J. pr.* 98, 480); 7.362 , 7.421 (Winkler, *J. pr.* 95, 414; 102, 278). S.H. (0° to 100°) 0.5695 (Bunsen, *P.* 141, 1). C.E. (0° to 100°) 0.000459 (Fizeau, *C. R.* 68, 1125). Characteristic lines in emission spectrum 4510.2, 4101.3, 4071.3, 4033.7, 3852.8, 3834.7, 3257.8, 3255.5, 3038.7, 3008, 2952.8, 2940.8, 2889.8, 2559.5, 2527.1, 2351.8, 2306.9 (Hagley, *T.* 1884, 102).

The observation of two indigo-blue lines in the spark-spectrum of a specimen of the *sinc-blende* of Freiberg in 1868 led Reich a. Richter to the discovery of indium (*J. pr.* 89, 444; 90, 175; 92, 480).

Occurrence.—In some *sinc-blende* from Freiberg (c. 1 p.c.), also from Durham (Flight, *B.* 10,

2054), and from Bohemia (Kachler, *J. pr.* 96, 447); in some Italian *galenas* (Denegri, *B.* 11, 1249); in various zinc ores (Tanner, *J.* 1874, 1227); in the fumes from zinc-ovens (Böttger, *J. pr.* 98, 26); in some tungsten ores (Hoppe-Seyler, *J.* 140, 547).

Preparation. Indium is more readily prepared from zinc which has been made from indium-containing bleides than from zincblende itself. The zinc is treated, for some days at the ordinary temperature, or for a shorter time at boiling temperature, with so much dilute H_2SO_4 or HCl that a small quantity remains undissolved; the residue contains In, with some Zn, and Pb, Cu, Cd, As, and Fe. There are many methods for obtaining In from this residue; that of Payer (*A.* 158, 372) is simple, and yields very pure In. The residue is washed, treated with a few drops of dilute H_2SO_4 (to remove any basic Zn salts), again washed thoroughly with hot water, dissolved in HNO_3 (any SnO_2 which may be present is allowed to remain), evaporated with excess of H_2SO_4 , until all HNO_3 is removed, (and treated with water; the solution now contains sulphates of In and the other metals which may be present, but the greater part of the PbSO_4 remains insoluble. Large excess of NH_4Aq is added, whereby hydroxides of In and Fe are pptd. with small quantities of hydroxides of Zn, Cd, Pb, and Cu; the pp. is well washed and dissolved in the smallest possible quantity of HCl ; the solution is boiled after addition of NaHSO_4 , until the smell of SO_2 is almost gone; a basic sulphite of In, $2\text{In}_2\text{O}_3 \cdot 3\text{SO}_2$, is thus pptd. as a fine crystalline powder. The pp. is free from salts of Cu, Zn, and Cd. If much Fe should have been present in the original Zn, small quantities of Fe salts may be pptd. by the action of the air during filtration; in this case ppn. should be conducted in CO_2 , or the pp. should be dissolved in NaHSO_4 and re-pptd. by boiling. The pp. may contain Pb salts and traces of alkali; it is dissolved in SO_4Aq , in which Pb sulphite is insoluble, after filtration In sulphite is pptd., free from Na salts, by boiling (*c.f.* Winkler, *J. pr.* 102, 278; Böttger, *J. pr.* 98, 26; R. E. Meyer, *A.* 150, 137. For methods of preparing In from zincblendes *c.* Reich & Richter, *J. pr.* 89, 441; 90, 175; 98, 480; Weselaky, *J. pr.* 94, 443; Richter, *J. pr.* 94, 414; Stolba, *D. P. J.* 198, 223). The pptd. basic In sulphite may be dissolved in H_2SO_4 ; after boiling off SO_2 , addition of NH_4Aq ppts. In_2O_3 , which when strongly heated yields In_2O_3 . In is obtained from the oxide (1) by heating in a stream of pure H, (2) by mixing with pure C, and heating to a very high temperature, (3) by heating with an equal weight of Na cut in small slices, under a layer of fused NaCl in a porcelain crucible, placed in a larger Hessian crucible, decomposing the alloy of Na and In so formed by water, and melting with Na_2CO_3 (Winkler, *J. pr.* 102, 275). Böttger (*J. pr.* 107, 89) recommends to ppt. In from solutions in H_2SO_4 by placing a stick of pure Zn in the liquid; he washes the pptd. metal with water, presses it with the finger, then between paper, and when quite dry fuses it under dry KCl.

Properties.—A silver-white, lustrous, ductile metal, softer than lead; leaves a mark when

rubbed on paper. Non-crystalline. Microscopically negative to Zn and Cd; much less volatile than these metals. Unchanged in air at ordinary temperatures; but burns to In_2O_3 , with blue-violet flame and brownish fumes, when strongly heated in air. Combines directly with Cl, Br, I, and S when heated. Boiling water is not decomposed by In. Soluble in dilute acids with evolution of H and formation of salts In_2X , where $\text{X} = \text{SO}_4, 2\text{NO}_3$, &c.

The at. w. of In has been determined (1) by synthesis of In_2O_3 from In (Reich & Richter, *J. pr.* 92, 484; Winkler, *J. pr.* 94, 8; 102, 282; Bunsen, *P.* 141, 28); (2) by analyses of In_2S_3 (R. & B., *l.c.*); (3) by decomposing NaAuCl_4 by In, and determining the Au (Winkler, *J. pr.* 102, 212); (4) by determining the V.D. of InCl_3 , InCl , and InI (Nilson & Petersson, *C. J.* 58, 814); (5) by determining the S.H. of In (Bunsen, *P.* 141, 1).

The atom of In appears to be monovalent (in InCl), divalent (in InCl_2), and trivalent (in InCl_3), in gaseous molecules; as the lower chlorides are decomposed by water with formation of In and InCl , it is probable that in solutions of its haloid compounds the atom of In is directly combined with at least three monovalent atoms.

In is distinctly metallic; with acid it evolves H and forms salts. A few basic, and some double, salts are known. In forms an ammonia alum. In_2O_3 reacts towards acids as a salt-forming hydroxide. In is closely related to Al and Ga, less closely to Tl; it is also related to the other earth-metals Sc, Yt, La, and Yb (*v.* EARTH METALS OF THE, vol. ii. p. 424). The investigation of In compounds is as yet far from complete.

Detection and Estimation.—In salts colour the flame blue-violet. Hoppe-Seyler (*A.* 140, 247) boils c. 1 gram of an In ore with *aqua regia*, neutralises by soda, filters, adds Na acetate, and ppts. by H_2S ; he dissolves the pp. in acid, and re-ppts.; the In_2S_3 is then tested in the flame after moistening with HCl . The spectral lines 4510.2 and 4101.3 are very characteristic. Boiling with NaHSO_4 causes ppn. of a fine crystalline pp. $2\text{In}_2\text{O}_3 \cdot 3\text{SO}_2 \cdot 8\text{H}_2\text{O}$; this salt is used for the estimation of In.

Indium bromide. InBr_3 . White crystalline tablets, *v.* sol. water; formed by heating In in a stream of CO , charged with Br, and subliming (R. Meyer, *A.* 150, 429). V.D. not determined.

Indium chlorides. In combines with Cl in three proportions, forming InCl , InCl_2 , and InCl_3 .

Indium monochloride. InCl . Mol. w. 148.77. V.D. at c. $1100^\circ\text{--}1400^\circ = 78.16$ (Nilson & Petersson, *C. J.* 53, 821). Obtained as a reddish black, vitreous, radiated, crystalline mass, by distilling InCl_2 (*q.v.*) on to In (rather more than the calculated quantity), heating for a little in a sealed tube, and distilling in a stream of CO (N. & P., *l.c.*). When melted InCl forms a dark-red liquid, in thick layers appearing almost black. Deliquescent; gradually decomposes in moist air, and quickly in water, to In and InCl_2 .

Indium dichloride. InCl_2 . Mol. w. 184.14. V.D. at $1000^\circ\text{--}1400^\circ = 99.62$ (Nilson & Petersson, *C. J.* 58, 820). White radiated crystals, obtained by heating In in its melting-point in a current of dry HCl free from air until an amber

INDOGEN *v.* **INDOXYL**.**INDOGENIC ACID** *v.* **INDOXYLIC ACID**.**INDOGENIDE OF BENZOIC ALDEHYDE**

$C_{11}H_9NO$ *i.e.* $C_6H_5\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle C_5H_4O$. *Benzylidene-ψ-indoxyl*. [176°]. Obtained by heating indoxylic acid with benzaldehyde (Baeyer, *B.* 16, 2197). Long flat orange needles. Sol. alcohol and chloroform to yellowish-red solutions, which have a yellowish-green fluorescence. In H_2SO_4 and strong HCl it dissolves with a deep-red colour; in alcoholic KOH with a greenish-blue, which gives the indigo spectrum.

(a) **INDOGENIDE OF ψ-ISATIN** IS **INDIBUBIN**.

(b) **Indogenide of ψ-isatin** is **INDIGO**.

Indogenide of ethyl-ψ-isatin is *Ethyl-indirubin* *v.* **INDIGO**.

INDOGENIDE OF p-NITRO-BENZALDEHYDE

$C_{11}H_7N_2O_3$ *i.e.*

$C_6H_4\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle C_5H_3(NO_2)$. *p-Nitro-benzylidene-ψ-indoxyl*. [278°]. Formed by adding an acetic acid solution of *p*-nitro-benzaldehyde to an aqueous solution of indoxyl acidified with HCl. Red needles (Baeyer, *B.* 16, 2199).

INDOGENIDE OF PYRUVIC ACID $C_{11}H_7NO_4$

i.e. $C_6H_5\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle C_5H_4CO_2H$. [197°]. Prepared by adding HCl to an aqueous solution of indoxyl and pyruvic acid (Baeyer, *B.* 16, 2199). Red needles. Easily soluble in alcohol and acetone. Dissolves with a red colour in alkalis, with a blue colour in conc. H_2SO_4 .

INDOLINE *v.* **INDIGO**.**INDOLE** C_8H_7N *i.e.* $C_6H_5\langle\begin{smallmatrix} CH \\ NH \end{smallmatrix}\rangle$. *Ketole*.

Mol. w. 117. [52°]. (254°) (Ciamician a. Zatti, *B.* 22, 1980). V.D. 4.45 (calc. 4.05). Occurs in small quantity in human excrement (Brieger, *J. pr.* [2] 47, 133).

Formation.—1. By passing the vapour of oxindole over heated zinc-dust (Baeyer, *A.* 140, 295; *Suppl.* 7, 56; Engler a. Jancke, *B.* 9, 1411).—2. By distilling with zinc-dust the yellow product of the action of tin and HCl on indigo (B.).—3. By fusing *o*-nitro-cinnamic acid with KOH and iron filings (Baeyer a. Emmerling, *B.* 2, 679; *Z.* [2] 6, 213; Beilstein a. Kuhlberg, *A.* 163, 141).—4. Formed to the extent of 5 p.c. in the passage through a red-hot tube of di-ethyl-*o*-toluidine, in less quantity from methyl-*o*-toluidine, in small quantity from methyl-ethyl-aniline, ethyl-acetanilide, and di-ethyl-aniline, and in trace only from ethyl-aniline when subjected to like treatment (Baeyer a. Caro, *B.* 10, 692, 1262).—5. By digesting albumen with pancreas and water at 40° to 45° for several days (Nencki, *B.* 8, 886; Kühne, *B.* 8, 206). According to Harris and Tooth (*J. Physiol.* 9, 220) its formation is due to a special micro-organism.—6. By distilling albumen (1 pt.) with KOH (8 pts.), the yield being about 25 p.c. (Engler a. Jancke, *B.* 9, 1411; Nencki, *J. pr.* [2] 17, 98).—7. By distilling (3,4,1)-nitro-propenyl-benzoic acid with lime (Widmann, *B.* 15, 2552).—8. By boiling aniline with di-chloro-acetic aldehyde or with di-chloro-di-ethyl oxide (Berlinerblau, *M.* 8, 180).—9. By heating *o*-chloro-*o*-amido-styrene with $NaOEt$ at 165° (Lipp, *B.* 17, 8067).—10. Together with ethane, ethylene, and propylene, by the distillation of *o*-cuminol

$C_8H_7(NH_2)(C_6H_5)$ over red-hot PbO (Filleti, *G.* 13, 881).—11. By the dry distillation of *o*-poly-oxamic acid (Mauthner a. Suida, *M.* 7, 288).—12. From phenyl-ethylene diamines by successive oxidation with CrO_3 and distillation over zinc-dust (Prudhomme, *B.* [2] 28, 558).—13. By fusing carbostyryl with potash (Morgan, *O. N.* 36, 239).—14. In small quantity, by heating the phenyl-hydrazone of pyruvic acid with $ZnCl_2$ at 200° (E. Fischer, *B.* 19, 1587).—15. By distilling calcium phenyl-amido-acetate with calcium formate (Mauthner a. Suida, *M.* 10, 268).

Preparation.—1. By heating aniline (50 g.) with an equal volume of water with inverted condenser and gradually adding di-chloro-ether (25 g.). After boiling for an hour the excess of aniline is distilled off, and the residue heated for 5 hours at 220° (Berlinerblau, *M.* 8, 180).—2. By distilling a mixture of calcium phenyl-amido-acetate with calcium formate, extracting the distillate with ether, shaking the ether with dilute acid to remove aniline, evaporating, and distilling with steam. The indole is purified by conversion into the picrate. The yield is 5 p.c. of the theoretical quantity (M. a. S.).

Properties.—Colourless laminae; mp. sol. hot water, v. sol. alcohol, ether, and ligroin. Readily volatile with steam. An alcoholic solution, acidified by HCl, dyes pine-wood yellow. Has a peculiar, but not very powerful, odour. It is a very weak base; with conc. HClAq it forms a sparingly soluble salt, decomposed by boiling water.

Reactions.—1. Suspended in water and subjected to the action of ozonised oxygen indole is converted into indigo and resinous products (Nencki, *B.* 8, 727, 1517). Indigo appears in the urine after subcutaneous injection of indole. 2. Aqueous CrO_3 yields a bulky violet-brown pp., insol. ether, chloroform, and benzene; sl. sol. alcohol, forming a red solution, sol. conc. HClAq (E. a. J.).—3. Heated with MeI it gives di-methyl-quinoline dihydride (Ciamician a. Zatti, *B.* 22, 1980).—4. When to an aqueous solution of indole there is added a few c.c. of HClAq, and then a large quantity of fuming HNO_3 (previously partially freed from nitrous fumes by evaporation), a red pp. is formed which may be purified by solution in alcohol and precipitation by adding ether. This substance, so-called nitroso-indole nitrate $C_8H_7(NO)N.HNO_3$, forms minute red needles, v. sl. sol. water and ether, v. sol. alcohol, nearly insol. dilute nitric acid. It decomposes sharply when heated. Alcoholic ammonium sulphide reduces nitroso-indole nitrate to so-called hydrozo-indole $C_8H_7N_2$ (?) which forms yellow needles, sol. alcohol and ether, melting at 140° to a deep-brown mass. Acids and alkalis convert it into a dark-brown colouring-matter termed azo-indole by Nencki.

Picrate $C_8H_7NO_4H_2(NO_3).OH$. Long red glittering needles.

Acetyl derivative C_8H_7NAc . [183°]. From indole and Ac_2O at 190° (Baeyer, *B.* 16, 1514). Long needles (from water) of four-sided pyramids (by sublimation).

(β) **Acetyl-indole** $C_8H_7\langle\begin{smallmatrix} C.CO.OH \\ NH \end{smallmatrix}\rangle CH_3$. *Methyl indyl ketone*. [190° cor.]. Obtained by heating

INDONAPHTHENE

5

(a)-carboxylic acid, prepared from methyl-ketole, with ten times its bulk of Ac_2O for 7 hours at 220° (Carlo-Zatti, *Rend. Accad. Linc.* [4] 4, 184; B. 22, 682). White needles. Sublimes in colorless plates; sl. sol. cold, v. sol. warm water and benzene; may be extracted from its aqueous solution by ether. Gives indole when heated with conc. HClAq . It readily yields an oxim and an oily phenyl-hydrazide. Potash fusion converts it into indole (β)-carboxylic acid [214°] identical with that obtained by oxidising skatole.

Picrate. [183°]. Needles; sl. sol. cold benzene.

Oxim $\text{C}_8\text{H}_7\text{C}(\text{NOH})\text{Me}$. [144° - 147°]. White needles.

$\text{C}_8\text{H}_7\text{C}(\text{CO}_2\text{H})\text{CH}_3$ [147° - 150°].

Prepared by heating indole (α)-carboxylic acid with Ac_2O and separated from the preceding by its greater solubility in water containing Na_2CO_3 and in boiling benzene (Zatti). Needles (by sublimation); sl. sol. boiling water. When boiled with aqueous KOH or K_2CO_3 , it yields (β)-acetyl-indole.

References. — DI-CHLORO-INDOLE, BENZYL-INDOLE, ETHYL-INDOLE, METHYL-ETHYL-INDOLE, ETHYL-INDOLE.

Isindole is DI-PHENYL-PYRAZINE (q. v.).

Di-indole v. Indoline under INDIGO.

Retin-indole $\text{C}_8\text{H}_7\text{NO}$? Obtained by treating di-chloro-indole (chloro-oxindole chloride) with HI dissolved in HOAc , passing in SO_2 , and ppg. with NaOH (Baeyer, B. 12, 1313). Amorphous; insol. NaOHAq , v. sol. alcohol and ether. Not volatile with steam. Its solution in HOAc mixed with HCl colours pine-wood red. On dry distillation yields indole.

INDOLE (α)-CARBOXYLIC ACID $\text{C}_8\text{H}_7\text{NO}_2$, i.e. $\text{C}_8\text{H}_6\text{CH}(\text{CO}_2\text{H})\text{CH}_3$ [201°].

Formation. — 1. By heating the phenyl-hydrazide of pyruvic ether with ZnCl_2 at 195° (E. Fischer, B. 19, 1567; A. 236, 140). — 2. By fusing (α)-methyl-indole (methyl-ketole) (1 pt.) with NaOH (15 pts.); the acid being ppd. by H_2SO_4 from the dissolved product; the yield is over 50 p.c. (Ciamician, a. a. Zatti, *Rend. Accad. Linc.* [4] 4, 746). — 3. From acetyl-(α)-methyl-indole $\text{C}_8\text{H}_7\text{CH}(\text{CH}_3)\text{CO}_2\text{Me}$ by potash fusion (Ciamician a. Magnanini, B. 21, 673).

Properties. — Needles (from water). M. sol. hot water and benzene, v. sol. alcohol and ether. May be sublimed in plates, but suffers partial decomposition thereby. At 230° it splits up into indole and CO_2 . Pine wood acidified with HCl is not coloured yellow by it. With isatin and H_2SO_4 , it gives a reddish-violet colouration. It forms a picric acid compound crystallising in slender golden needles. Its Ba salt is soluble. Ac_2O at 220° forms (β)-acetyl-indole and di-acetyl-indole.

Anhydride $\text{C}_8\text{H}_5\text{N}_2\text{O}$, i.e. $\text{C}_8\text{H}_4\text{N}_2\text{O}_2$.

$\text{C}_8\text{H}_7\text{CH}(\text{CO}_2\text{N})\text{CH}_3$ [312° - 315°]. Mol.

Confirmed by Bault's method (Magnanini, B. 22, 2503). Formed by boiling the acid with

Ac_2O using an inverted condenser. Yellow needles.

Methyl-ether MMA. [152°]. Needles. Indole (β)-carboxylic acid

$\text{C}_8\text{H}_6\text{CH}(\text{CO}_2\text{H})\text{CH}_3$ [214°]. Formed by fusing (β)-methyl-indole (skatole) with KOH (Ciamician, Magnanini a. Zatti, B. 21, 673, 1929). Obtained also by fusing (β)-acetyl-indole with caustic potash (Zatti, B. 22, 664). Plates (from water), decomposed on fusion. Sl. sol. benzene and boiling water, m. sol. alcohol and ether, almost insol. ligroin. Its aqueous solution evolves CO_2 on boiling. With isatin and H_2SO_4 , it gives a brownish-violet colour. Its ammonium salt gives pps. with CuSO_4 and with FeCl_3 . It does not yield a picric acid compound.

Indole di-carboxylic acid

$\text{CO}_2\text{H.C}_8\text{H}_6\text{CH}(\text{CO}_2\text{H})\text{CH}_3$ [above 250°]. Obtained by saponifying its acid ether, which is formed when $\text{CO}_2\text{Et.C}_8\text{H}_6\text{CH}(\text{CO}_2\text{Me})\text{CO}_2\text{Et}$, the product of the condensation of hydrazido-benzoin ether with pyruvic ether, is heated with zinc dust (Roder, A. 236, 169). Slender needles, sol. hot alcohol and acetic acid, sl. sol. ether and water. Does not colour pine wood. Decomposed on fusion giving off CO_2 and yielding a product that behaves like indole towards pine wood.

Mono-ethyl ether EtHA. [260°]. Yellow needles (from HOAc).

INDOLES. Alkylated derivatives of indole may be formed synthetically in the following ways: (a) By removal of NH_2 from the phenyl-hydrazides of ketones, aldehydes, or ketonic acids. Thus with the phenyl-hydrazide of acetone $\text{C}_8\text{H}_6\text{N}_2\text{H.CMe}_2 = \text{NH}_2 + \text{C}_8\text{H}_6\text{CH}(\text{CH}_3)_2$, and in like manner from the phenyl-methyl-hydrazide of pyruvic acid $\text{C}_8\text{H}_6\text{N}_2\text{H.Me.CMe.CO}_2\text{H} = \text{NH}_2 + \text{C}_8\text{H}_6\text{CH}(\text{NMe})\text{CO}_2\text{H}$ (E. Fischer, A. 236, 116). (b) By elimination of NH_2 from alkylated di-pyrroles: —

(Dannstedt, B. 21, 3429). (c) By heating (β)-bromo- β -acetyl-propionic acid with aromatic amines (Wolf, B. 21, 3366). Thus o- or p-toluidine gives tri-methyl-indole; (β)-naphthylamine gives di-methyl-(β)-naphthylindole; while ethyl-aniline forms di-methyl-ethyl-indole:

Indoles may be converted by alkyl iodides into derivatives of quinoline dihydride:

INDOLINE v. INDIGO.

INDONAPHTHENE. The hypothetical hydrocarbon C_{12}H_8 or $\text{C}_{12}\text{H}_7\text{CH}(\text{CH}_3)\text{CH}_3$ which stands in the same relation to indole that naphthalene stands to quinoline (Baeyer a. Perkin, *Ann.* B. 17, 122). The name *indene* has also been proposed for

INDONAPHTHENE.

the same hydrocarbon (Roser, *A.* 247, 132); v. also **METHYL-INDONAPHTHENE**. Besides the methods mentioned below, indonaphthene derivatives may be formed by condensation of naphthalene derivatives. Thus $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \cdot \text{CO} \\ \diagup \quad \diagdown \\ \text{CHCl} \cdot \text{CCl} \end{smallmatrix}$, a product of

the chlorination of (8)-naphthoquinone is converted by cold aqueous NaOH into

which may be oxidised by chromic acid to

INDONAPHTHENE DIHYDRIDE CARBOXYLIC ACID $\text{C}_{16}\text{H}_{14}\text{O}_4$, i.e.

Formation.—1. By heating the corresponding di-carboxylic acid until the evolution of CO_2 has ceased, and distilling the product (Baeyer & Perkin, jun., *B.* 17, 122; Perkin, jun., *C. J.* 53, 7); the resulting ether being saponified. Trimetric plates; m. sol. hot water, alcohol, and ether, sl. sol. cold water. When heated above 200° it gives off CO_2 and leaves the mono-carboxylic acid.— $\text{Ag}_2\text{A}'$: white amorphous pp. becoming crystalline; sl. sol. water.

Properties.—Colourless needles (from water); may be distilled when quickly heated. Sl. sol. cold water. On oxidation with KMnO_4 it yields phenyl-glyoxylic acid. It forms a bulky white silver salt, sl. sol. hot water.

Indonaphthene dihydride dicarboxylic acid

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \diagup \quad \diagdown \\ \text{CH} \end{smallmatrix} \text{C(CO}_2\text{H)}_2$. [199°]. Formed by the action of di-*o*-bromo-*o*-xylene on malonic ether (1 mol.) and NaOEt (2 mols.) in ether (Baeyer & Perkin, jun., *B.* 17, 122; Perkin, jun., *C. J.* 53, 7); the resulting ether being saponified. Trimetric plates; m. sol. hot water, alcohol, and ether, sl. sol. cold water. When heated above 200° it gives off CO_2 and leaves the mono-carboxylic acid.— $\text{Ag}_2\text{A}'$: white amorphous pp. becoming crystalline; sl. sol. water.

INDONAPHTHOQUINONE $\text{C}_{16}\text{H}_8\text{O}_2$, i.e.

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CH}_2$. [181°]. **Di-keto-indonaphthene. Di-keto-hydrindene.** Formed by warming its carboxylic ether $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \end{smallmatrix} \text{CH} \cdot \text{CO}_2\text{Et}$ with alkalis (Wialicenus, *A.* 246, 351). Best obtained by acidifying an aqueous solution of the sodium derivative $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \end{smallmatrix} \text{CH} \cdot \text{CO}_2\text{Na}$ with ether, and leaving the ethereal solution to stand, when CO_2 is given off.

Properties.—Small needles (from benzene-ligroin); v. sol. hot alcohol and benzene, m. sol. ether and hot ligroin, v. sl. sol. cold ligroin and water. Dissolves in alkalis with intense yellow colour.

Reactions.—1. Gives a phenyl-hydrazide $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C(N}_2\text{HPh)} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CH}_2$ [163°] crystallising in yellow needles, insol. water and ligroin, v. e. sol. ether and benzene. With phenyl hydrazine at 100° it gives rise to a di-phenyl-hydrazide $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C(N}_2\text{HPh)} \\ \diagup \quad \diagdown \\ \text{C(N}_2\text{HPh)} \end{smallmatrix} \text{CH}_2$, which forms flesh-coloured plates [171°], and when dissolved in H_2SO_4 is coloured deep bluish-green by FeCl_3 (W.

Wialicenus & Kötale, *A.* 252, 73).—2. Forms a nitroso-derivative $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C:NOH}$.

[198°] crystallising from HOAc in triangular plates.—3. **Benzoic aldehyde** at 120° forms $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C:OHPH}$ [150°].—4. Gives with

bromine a compound $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C:OBr}$, [177°] crystallising in plates, m. sol. hot alcohol and HOAc, v. sol. ether and CH_2 (Zincke, *B.* 20, 3216). This di-bromo-derivative, which is also formed by the action of

bromine on $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{C(NH)} \end{smallmatrix} \text{C:NH}_2$ and on

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{C(NH)} \end{smallmatrix} \text{CH}$, is converted by the action of alkali into bromoform, phthalic acid, and the compound $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C:OBr}$ [118°].

Br forms again the original $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C:OBr}$,

while Cl forms $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CClBr}$ [147°] (Zincke, *B.* 21, 2394). The corresponding $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CCl}_2$ [125°] is formed by the action

of chlorine on $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \cdot \text{CO} \\ \diagup \quad \diagdown \\ \text{CCl} \cdot \text{CCl} \end{smallmatrix}$ dissolved in aqueous Na_2CO_3 .

Indonaphthoquinone carboxylic ether

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CH} \cdot \text{CO}_2\text{Et}$. [78°]. Formed by the action of NaOEt (2 mols.) on phthalic ether (1 mol.) and subsequent treatment with acetic ether, the product $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{ONa} \cdot \text{CO}_2\text{Et}$ being treated with dilute H_2SO_4 (Wislicenus, *A.* 246, 349). Slender yellow needles, insol. water, v. a. sol. alcohol, ether, benzene, and ligroin. FeCl_3 colours its alcoholic solution deep red. Dissolves in aqueous Na_2CO_3 , expelling CO_2 . If its alkaline solution be boiled and then acidified CO_2 is evolved and indonaphthoquinone liberated. It forms a phenyl-hydrazide. If its acid solution is boiled with water there is formed $\text{C}_{16}\text{H}_{10}\text{O}_4$, which dyes wool violet-red and forms crystalline $\text{C}_{16}\text{H}_8\text{Br}_2\text{O}$ [196°] and $\text{C}_{16}\text{H}_8\text{Br}_4\text{O}$ [242°].

Salts.— $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{Na}$ aq: yellow needles (from water). Gives with MeI the compound $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{OMe} \cdot \text{CO}_2\text{Et}$, crystallising in prisms [74°] v. e. sol. alcohol and ether, insol. water, sol. NaOH aq with rose colour.— $(\text{C}_{16}\text{H}_8\text{O}_4)_2\text{Cu}$: green crystals (from alcohol).

INDONE. The ketone $\text{C}_{16}\text{H}_{10}\text{O}$, i.e.

number of the hasid derivatives of which have been described by Roser (*A.* 247, 132). Indone may also be viewed as the anhydride of **ox-indonaphthene**.

INDOPHANE $\text{C}_{16}\text{H}_8\text{N}_2\text{O}$, a blue substance, resembling indigo, produced, together with naphthyl-purpuric acid, by adding a hot concentrated solution of KOCy (45 g.) to di-nitro-naphthol (80 g.) dissolved in boiling water (3 litres) to which just enough NH_3 has been added to effect

solution (Hlasiwetz; Sommaruga, *B. C.* 1871, 617). Violet mass with green lustre; insol. water, alcohol, ether, benzene, and CS_2 ; m. sol. H_2SO_4 and hot $HOAc$, forming purple solutions. May be sublimed. Nitric acid converts it into a brownish-red body, soluble in alkalis. Ferrous sulphate, mixed with lime reduces it. Aqueous KOH forms $C_{12}H_7KN_2O_4$, a body greatly resembling indigo; $NaOH$ acts in like manner.

INDOPHENIN ($C_{12}H_7NOS$). Formed by shaking isatin (1 pt.) with H_2SO_4 and benzene that contains thiophene: $C_4H_4N_2O + C_6H_6S = H_2O + C_{12}H_7NOS$ (Baeyer, *B.* 12, 1309; 16, 2188; 18, 2637; V. Meyer, *B.* 15, 2893; 16, 1205; P. Meyer, *B.* 16, 2269; Gumpert, *J. pr.* [2] 32, 278). Blue powder, which exhibits a coppery lustre when rubbed, or small needles (from alcohol-phenol). Insol. water, benzene, and ligroin, v. sl. sol. alcohol, ether, and CS_2 , sl. sol. $HOAc$. In H_2SO_4 , it forms a blue solution, whence it is pptd. by water. Cannot be sublimed. May be reduced by zinc-dust and $HOAc$ to a colourless body which is re-oxidised to indophenin on exposure to air. Bromo-, di-bromo-, and methyl-indophenins may be formed in like manner by using bromo-, di-bromo-, or methyl-isatin in place of isatin in the above preparation.

INDOPHENOLS. Quinonimides of the formula $C_6H_4 \begin{smallmatrix} \text{NH} \\ \diagup \text{R} \diagdown \end{smallmatrix}$, where R' is an aromatic radicle containing hydroxyl (cf. INDAMINES). Thus when a mixture of di-methyl-*p*-phenylene-diamine and (α)-naphthol is oxidised with $NaOCl$ or $K_2Cr_2O_7$, there is formed the dark-blue indophenol $C_6H_4 \begin{smallmatrix} \text{NMe}_2 \\ \diagup \text{Cl} \diagdown \end{smallmatrix}$ (Pabst, *Bl.* [2] 38, 161); while *p*-amido-phenyl-piperidine mixed with phenol and oxidised by K_2FeO_4 , forms a similar body $C_{12}H_{11} \begin{smallmatrix} \text{N.C}_6H_4\text{OH} \\ \diagup \text{N.C}_6H_4\text{OH} \end{smallmatrix}$ (Lellmann a. Geller, *B.* 21, 2288).

INDOXANTHIC ETHER $C_{11}H_{11}NO$, i.e. $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{NH} \end{smallmatrix} > C(OH).CO_2Et$. [107°]. Prepared by the careful oxidation of indoxyl ether with $FeCl_3$ (Baeyer, *B.* 15, 775). Yellow needles or monoclinic prisms. Sol. water and ether. On further oxidation it gives $CO_2H.C_6H_4.NH.CO.CO_2Et$. On reduction it is reconverted into indoxyl ether. Decomposed by alkalis with formation of anthranilic acid.

Nitrosamine $C_6H_4 \begin{smallmatrix} \text{C(OEt)} \\ \diagup \text{N(NO)} \end{smallmatrix} > CH$. [118°]. Light-yellow needles or tables. Sol. alcohol and ether, sl. sol. water.

INDOXYL C_8H_7NO i.e. $C_6H_4 \begin{smallmatrix} \text{C(OH)} \\ \diagup \text{NH} \end{smallmatrix} > CH$ (stable form) or $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{NH} \end{smallmatrix} > CH_2$ (transition form).

Formation.—1. By warming potassium indoxyl-sulphate with HCl or H_2SO_4 .—2. By heating indoxyl ether alone or with H_2SO_4 (Baeyer, *B.* 14, 1744).—3. By boiling *o*-nitro-phenyl-acetylene with acid ammonium sulphate, and treating the product with zinc-dust and ammonia (Baeyer, *B.* 15, 567).—4. By reducing isatogen-sulphuric acid with zinc-dust and ammonia.

Properties.—Oil. Not volatile with steam.

In the pseudo-form $C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{NH} \end{smallmatrix} > CH_2$, it is not known in the free state, but di-substitution products of ψ -indoxyl are stable. Nevertheless indoxyl forms condensation products, called indogenides, with bodies containing a CO group, in which reactions it must be supposed first to change into the pseudo-form.

Reactions.—1. In alkaline solution it is rapidly oxidised in the air to indigo. $FeCl_3$ forms a white amorphous body, which is immediately converted by HCl into indigo (E. Baumann a. Tiemann, *B.* 13, 415).—2. Indoxyl is not affected by H_2SO_4 or conc. $HClAq$, but dilute $HClAq$ converts it into an amorphous red substance.—3. A solution in H_2SO_4 , treated with *o*-nitro-phenyl-propionic acid gives indoin.—4. On warming with a solution of Na_2CO_3 and *o*-nitro-phenyl-propionic acid, indigo is produced.—5. By the action of Na_2CO_3 upon an alcoholic solution of isatin and indoxyl there is formed indirubin, while with bromo-isatin the product is bromo-indirubin (Baeyer).—6. Bromine gives tri-bromo-aniline (E. Baumann a. Tiemann, *B.* 12, 1192).—7. In alkaline solution $K_2S_2O_8$ forms indoxyl-sulphuric acid.—8. *Diazo-benzene chloride* forms $C_6H_4 \begin{smallmatrix} \text{C(OH)} \\ \diagup \text{N.N}_2\text{Ph} \end{smallmatrix} > CH$? [236°] (Baeyer, *B.* 16, 2190).

Nitrosamine $C_6H_4 \begin{smallmatrix} \text{C(OH)} \\ \diagup \text{N(NO)} \end{smallmatrix} > CH$. Formed

by the action of nitrous acid on indoxyl (Baeyer, *B.* 16, 2188). Slender yellowish needles. When boiled with HCl it gives indigo.

Isonitroso-derivative of ψ -indoxyl

$C_6H_4 \begin{smallmatrix} \text{CO} \\ \diagup \text{NH} \end{smallmatrix} > C:NOH$. See *oxim* of ψ -ISATIN.

Ethyl derivative $C_6H_4 \begin{smallmatrix} \text{C(OEt)} \\ \diagup \text{NH} \end{smallmatrix} > CH$.

Formed by heating the ethyl derivative of indoxyl ether with HCl (Baeyer, *B.* 17, 781). Smells like indole, and colours pine wood, acidified with HCl , brownish-red. Its picric acid compound, $C_{10}H_7 \begin{smallmatrix} \text{NO}_2\text{C} \\ \diagup \text{NH} \end{smallmatrix} > C(OH).OH$ forms brown needles. Its **nitroso-derivative**

$C_6H_4 \begin{smallmatrix} \text{C(OEt)} \\ \diagup \text{N(NO)} \end{smallmatrix} > CH$ forms yellow prisms [85°], sol. alcohol, insol. water, and converted into indigo by heating with HCl (Baeyer, *B.* 17, 781).

Indoxyl-sulphuric acid $C_8H_7NSO_4$. Occurs in the urine of herbivora and, in smaller quantity, in that of man (Schunck, *P. M.* [4] 14, 288; Hoppe-Seyler, *C. B.* 1864, 511; *H.* 8, 79; E. Baumann a. Tiemann, *B.* 13, 408). When indole is introduced into a dog by injection or in food large quantities of indoxyl-sulphuric acid appear in the urine (Jaffé, *Fv.* 11, 358; E. Baumann a. Brieger, *H.* 3, 254). Indoxyl-sulphuric acid is also formed by adding $K_2S_2O_8$ to a solution of indoxyl in aqueous KOH (Baeyer, *B.* 14, 1745).

Potassium salt— KA' . Plates (from hot alcohol). V. sol. water, v. sl. sol. cold alcohol. Not affected by KOH even at 170°. Decomposed by hot dilute HCl or H_2SO_4 , or even by water at 120°, into indoxyl and $KHSO_4$. When warmed with $FeCl_3$ and a little HCl it is entirely converted into indigo. Indigo is also formed when the salt is heated alone.

INDOXYLIC ACID.

INDOXYLIC ACID C_8H_7NO , i.e.

Formed by saponifying its ether with fused NaOH at 180°. White crystalline pp., sl. sol. water. In dilute alkali solutions it is converted into indigo by the action of air or oxidising agents. On heating it splits off CO_2 , forming indoxyl.

Indoxyllic ether $C_8H_7N(OH)CO_2Et$. Colourless prisms, [121°]; dissolves in alkalis and is reppd. by CO_2 . Prepared by reduction of isotogenic ether or o-nitro-phenyl-propionic ether. Heated with H_2SO_4 it gives indigo-sulphonic acid. On oxidation it gives successively indoxanthidic ether $C_{11}H_9N_3O_3$, indoxanthic ether $C_{11}H_9NO_3$, and hydrogen ethylazoxyl-o-amido-benzoate $CO_2Et \cdot CO \cdot NH \cdot C_6H_4 \cdot CO_2H$.

Acetyl-indoxyllic ether

Ethyl-indoxyllic ether

Ethyl-indoxyllic acid

Nitroso-ethyl-indoxyllic acid

INDUCTION. When H and Cl are mixed in equal volumes and exposed to sunlight a measurable time elapses before chemical change begins. Hansen & Roscoe, who examined this phenomenon (T. 1857, 855), regarded the mixture as resisting chemical change, and they used the term *induction* to express the gradual overcoming of this resistance. The term has also been used by Wright, who noticed a similar phenomenon in the reduction of metallic oxides by CO and H (C. J. Trans. 1879, 475; 1880, 757); v. CHEMICAL CHANGE, vol. iv p. 749.

M. M. P. M.

INDULINES (O. N. Witt & A. Thomas, C. J. 48, 112). Coloured compounds formed by the action of such bodies as azo-, amido-azo-, nitro-, or nitroso- compounds on the hydrochlorides of certain aromatic amines with elimination of NH_3 . Aniline hydrochloride gives a dark-blue colouration with amido-azo-benzene. Hofmann & Geyger (B. 5, 474) supposed that only one dye-stuff was formed: $C_{12}H_{11}N_3 + C_6H_5N = C_{18}H_{16}N_4 + NH_3$. In reality a great number of dye-stuffs are got. If the mixture of diazo-benzene anilide (1 pt.), aniline (4 pts.), and aniline hydrochloride (1 pt.), which has been left until the diazo-benzene anilide has changed into amido-azo-benzene, be heated at 100° for 24 hours, crystals of azophenine $C_{18}H_{16}N_4$ separate. This forms garnet-coloured leaflets (from aniline) [287°] (v. AZOPHENINE). If the mixture of aniline, aniline hydrochloride, and amido-azo-benzene, after heating at 100° till azophenine is formed, be further heated at 125°-180° for 12 hours, the azophenine disappears, and the mass turns blue. If it be slowly cooled crystals are formed. These may be separated from the

mother-liquor (which contains 'induline B'), washed with spirit and with boiling water, and recrystallised from aniline mixed with aniline hydrochloride. So obtained, induline 8 B forms glistening brown leaflets, $C_{18}H_{16}N_4 \cdot HCl$. It is insol. cold, sol. hot, spirit, and v. sol. aniline. Alcoholic NaOH liberates the free base, which forms purple solutions with alcohol and with aniline. Induline 8 B is sky-blue. Its sulphonic acid resembles that of induline B.

Induline 6 B— $C_{18}H_{16}N_4$. Is formed by heating a mixture of amido-azo-benzene (100 pts.), aniline hydrochloride (180 pts.), and aniline (800 pts.), for 5 hours at 110°, then adding more aniline hydrochloride (66 pts.), and heating to 165°-170°. The hydrochloride, $RHCl$, separates as green crystals. The free base separates from aniline as brilliant green needles. The solution of this base is of a dark bluish-purple colour. The hydrochloride is insoluble in the usual solvents, and is hardly soluble in aniline. It dissolves in phenol and in H_2SO_4 , forming a greenish-blue solution.

Induline B hydrochloride is v. sol. spirit, sl. sol. water, v. sol. a conc. aqueous solution of aniline hydrochloride. The base forms a brown-red spirit solution. The sulphonic acid is insol. water, but its neutral alkaline salts form reddish-blue aqueous solutions.

Formation of indulines is due to the dehydrogenating action of amido-azo-benzene, which itself becomes aniline and p-phenylene diamine, the latter then entering into the reaction. Azo-benzene, phenyl-amido-azo-benzene, chrysoidine, nitroso-di-methyl-aniline, and even amido-azo-naphthalene, may be substituted for amido-azo-benzene, but if instead of aniline o-toluidine or naphthylamine be used, red dyes are got (azotoline, &c.). This would indicate that azophenine was an oxidation product of aniline, and not derived from the amido-azo-benzene. In the preparation of azophenine by heating aniline (4 pts.) with aniline hydrochloride (1 pt.) and amido-azo-benzene (2 pts.) at 85°, ammonium chloride and p-phenylene-diamine are constant by-products, indicating that phenylation and reduction of the amido-azo-benzene has taken place (Witt, B. 20, 1538). When azophenine (400 g.) is boiled with alcohol (40 litres) and strong H_2SO_4 (2 kilos.) for 10 hours quinone dianilide (195 g.) is formed. The compound

Fischer & Hepp for azophenine, which is also consistent with its formation from nitroso-di-

aniline on azophenine, induline (6 B) of the formula $NH_2 \cdot C_6H_4 \cdot (NHPh)_2 \cdot \begin{array}{c} \diagup NPh \\ \diagdown N \end{array} > C_6H_5$ might be formed. A mixture of 3 B and 6 B induline is formed by heating p-nitroso-di-phenylamine with aniline and aniline hydrochloride in alcoholic solution at 180°. By heating p-nitroso-di-

INOSITE

phenyl-amine (1 pt.) with aniline hydrochloride (1 to 2 pts.) and aniline (4 pts.) at 135°-140°, a very rich yield of induline is obtained, which chiefly consists of 6B. If pure asophaeline is heated at 140° with equal parts of aniline and aniline hydrochloride 6B induline is almost exclusively formed (Fischer, A. Hepp, B. 20, 2484). By the action of azo-, nitro-, or nitroso-compounds on *m*- or *p*-diamines, indulines which are soluble in water are formed, e.g. *paraphenylenes blue*.

Resinduline $C_{24}H_{18}N_2$, i.e.

$C_6H_5(NPh) \langle \begin{smallmatrix} N \\ NPh \end{smallmatrix} \rangle C_6H_5$. [225°]. Formed by the action of nitroso-phenyl-(α)-naphthylamine hydrochloride on aniline and aniline hydrochloride at 120° (O. Fischer, B. 21, 2621). Formed also by oxidising tri-phenyl-tri-amido-naphthalene $C_{18}H_6(NHPh)_3$ [1:2:4]. Red plates, almost insol. water, sol. alcohol, v. sol. benzene. Reduced by HI and P at 150° to a yellowish-red base and aniline. Zinc and HCl give naphthalene and aniline.

Salts.— $BHCl \frac{1}{2}aq$: reddish-brown prisms. — BH_2SO_4 . — $BHNO_3$. [231°]. — **Picrate**: plates, insol. water.

INDYL PHENYL KETONE CARBOXYLIC

ACID $C_{17}H_{11}O_3$, $CH_3 \cdot CO \cdot C_6H_4 \cdot \langle \begin{smallmatrix} CH \\ NH \end{smallmatrix} \rangle \cdot CO_2H$. *Benzoin-dole carboxylic acid*. [285°]. From the *esobenzoyl-phenyl-hydrazone* of pyruvic acid by heating with $ZnCl_2$ at 220° (Ruhemann & Blackman, O. J. 55, 617). White needles, sl. sol. boiling water. Decomposes on fusion.

INOGEN v. MUSCLE

INOSIC ACID $C_{10}H_{11}N_5O_7$? Occurs in the mother-liquor in the preparation of creatine from flesh (Liebig, A. 62, 317; A. Ch. [3] 33, 129). Occurs to the extent of $\frac{1}{10}$ p.c. in the flesh of hens. Pigeon's flesh and human flesh contains none (Gregory, A. 64, 106; Schlossberger, A. 66, 32). It is found in some fish (Limpricht, A. 133, 101).

Preparation.—The filtrate from which creatin has separated is concentrated, then mixed with alcohol till it acquires a milky consistence, and left to itself for a few days. It then deposits a crystalline mixture containing the inosates of Na and Ba. The crystals are dissolved in hot water and BaCl₂ added. The Ba salt crystallises on cooling.

Properties.—Uncrystallisable; v. sol. water, forming a solution with a flavour of broth, whence alcohol ppt. it as an amorphous powder. Insol. ether.

Salts.— $KA' \frac{1}{2}aq$: long, four-sided prisms, v. sol. water, insol. alcohol. — $BA' 6aq$: prisms. S. 25 at 16°.

INOSITE $C_6H_8O_5$. *Phaseomannite*. [217°] (Maquenne); [235° cor.] (Kirk). (319° in *vacuo*) [M.]. S.G. (of $C_6H_8O_5, 2aq$) 1.524. S.G. (of $C_6H_8O_5$) 1.752. S. (of $C_6H_8O_5, 2aq$) 10 at 124 (T. s. v.); 13 at 19° (Rok). H. C. 666500. H. F. 811500 (Berthelot & Recoura, C. R. 105, 143). Discovered by Scherer (A. 73, 322; 81, 375) in muscular substance (i. e., *lvs.*, muscle). It occurs especially in the heart, but also in the lungs, kidneys, liver, and spleen of oxen (Cloetta, A. 99, 289), in the brain of oxen (W. Müller, A. 103, 140), in human kidneys, and in the urine in a case of Bright's disease to the amount of .1 p. c.

and sometimes in healthy urine (Küls, Fr. 16, 185). Found also in birds, in cephalopoda (Krukenberg, J. Th. 1881, 443), and in the flesh of a young porpoise (O. Jacobsen, A. 157, 927). Inosite occurs in green kidney beans (*Phaseolus vulgaris*) (Vohl, A. 99, 125; 105, 630), in the green pods and unripe seeds of pea (*Pisum sativum*), in unripe lentils (*Eryum Lens*), in the unripe fruits of the common acacia (*Robinia Pseud-Acacia*), in the heads of the common cabbage (*Brassica oleracea*, var. *capitata*), in foxglove leaves, in extract of digitalis, in the leaves of the dandelion (*Taraxacum dens leonis*), in potato shoots, in green asparagus and in its berries, in *Lactaria piperatus*, in *Clavaria crocea* (Marmé, A. 129, 222), in the leaves of the common ash (*Fraxinus excelsior*) (Gint, J. pr. 104, 491), in grape juice (Hilger, A. 160, 333), in young vine leaves (Neubauer, Fr. 12, 45), in walnut leaves (Tanret & Villiers, A. Ch. [5] 23, 389; C. R. 86, 486; Maquenne, C. R. 104, 250).

Preparation.—1. Walnut leaves are extracted with water. The brown liquid is treated, at 100°, with excess of milk of lime, filtered, ppd. with lead acetate, again filtered and treated with ammonia and lead acetate. The crude lead compound of inosite is treated with dilute sulphuric acid, and the inosite is ppd. with alcohol and ether. It can be further purified by recrystallisation from hot dilute acetic acid (Hilger; Maquenne).—2. The fresh-chopped tissue is covered with water, and allowed to stand for 24 hours in a cool place, with frequent stirring; the liquid is then separated, and the residue pressed; the solution is heated with a little acetic acid to separate albumin and hematin, then strained, evaporated on the water-bath to one tenth, ppd. with neutral acetate of lead, and filtered; and the filtrate is mixed with basic acetate of lead, whereupon inosite is thrown down in combination with oxide of lead, accompanied by uric acid, cystine, and other substances. The pp., after washing, is decomposed under water by H_2S , and the liquid filtered from the sulphide of lead; it then sometimes deposits crystals of uric acid, and when evaporated to a small bulk on the water-bath, and mixed with alcohol till a turbidity is produced, it yields crystals of inosite (Cloetta).—3. Crystals of inosite may often be obtained by evaporating an aqueous liquid containing it, and adding three volumes of alcohol to one of the boiling liquid (Cooper Lane, A. 117, 118).

Properties.—Monoclinic crystals (containing 2aq) $a:b:c = 1.090:1.535:\beta = 111:89^\circ$. Effloresces in dry air. At 100° it gives off its water of crystallisation. It has a sweet taste and is optically inactive. Sl. sol. cold dilute alcohol, insol. absolute alcohol and ether. Does not combine with NaCl or KCl. With lead subacetate it forms a gelatinous pp. which may be $C_6H_8O_5, 2PbO$. Inosite does not react with phenyl-hydrazine (E. Fischer, B. 17, 593). Inosite is not turned brown by boiling alkalis, or by boiling dilute H_2SO_4 . It does not reduce Fehling's solution but forms a green pp. It will not undergo alcoholic fermentation. In presence of decaying cheese or of putrid meat and chalk it forms butyric and lactic acids. Sodium-amalgam does not affect inosite. Inosite does not form an acid solution with borax.

Reactions.—1. Evaporated with *nitric acid* it leaves a residue which gives with CaCl_2 in ammoniacal solution a rose-red colouration (colour test).—2. When a solution of inosite is evaporated nearly to dryness and a drop of mercuric nitrate solution is added there is formed a yellow pp. which turns red on warming (Gallois, *Fr.* 4, 264).—3. Heated with oxalic acid it gives CO_2 and formic acid. According to Lorin (*Bl.* [2] 48, 235), this indicates that it is a polyhydric alcohol.—4. HIAg at 170° gives a trace of benzene, phenol, and tri-iodo-phenol [153°].—5. It forms no addition products with chlorine and bromine.—6. It does not reduce boiling ammoniacal AgNO_3 , but on adding KOH a mirror is formed.—7. *Chromic acid* oxidises it to CO_2 and formic acid in the solid.—8. KMnO_4 gives CO_2 .—9. Conc. HNO_3 at 100° forms oxalic acid, but in an open dish on the water-bath it gives on evaporation a white substance which dissolves in water, and the solution, mixed with alcohol and evaporated, then deposits black crystals of tetra-oxo-quinone. HNO_3 also forms rhodozonic acid (Maquenne, *Bl.* [2] 47, 290). According to Maquenne this reaction, and reaction 4 indicate that inosite is hexa-oxo-benzene hexahydrate.

Hexa-acetyl derivative $\text{C}_6\text{H}_4(\text{OAc})_6$, [212°] (234° *in vacuo*). From inosite and AcCl or Ac_2O . Sublimes at 200° . Insol. water, sol. hot alcohol and Ac_2O . Saponified by alkalis and strong acids (Maquenne, *C. R.* 104, 1719; *Bl.* [2] 48, 58). According to Fick (*C. C.* 1887, 452), the acetyl derivative is $\text{C}_6\text{H}_4\text{Ac}_6\text{O}_6$ and melts at 216° cor.

Hexa-benzoyl derivative $\text{C}_6\text{H}_4(\text{OBz})_6$, [258°]. Minute needles. Insol. all usual solvents.

Hexa-nitroxyl derivative $\text{C}_6\text{H}_4(\text{ONO})_6$, 'Nitro-inosite.' [120°]. Formed by adding a solution of inosite in fuming HNO_3 to conc. H_2SO_4 . May be crystallised from alcohol, a crystalline tri-pitroxyl derivative being left in the mother-liquor. Trimetric tables; insol. water, v. sol. alcohol. Detonates when struck. Cold alcoholic KOH decomposes it forming KNO_3 , the inosite being completely broken up. When boiled with alcohol and a little H_2SO_4 , the products are nitrous ether and inosite.

INULIN ($\text{C}_6\text{H}_{10}\text{O}_5$), or $\text{C}_{12}\text{H}_{22}\text{O}_{11}$. *Helenin*. *Alantinn*. *Menyanthin*. *Dahlin*. *Synanthrin*. *Sinistrin*. Mol. w. 1980 (by Raoult's method. Brown & Morris, *C. J.* 55, 464). [160°]. S.G. 1.35 (Kiliani); 1.36 (Payen); 1.46 (Dubrunfaut); 1.47 (Dragendorff). [α] $_D$ = -35° (Dubrunfaut, *C. R.* 42, 803); -38.5° (Lescour & Morelle, *C. R.* 87, 216); -40° (Lefranc, *J. Ph.* [5] 2, 216). H.C. 684900 (Berthelot & Vieille, *Bl.* [2] 47, 868; *A. Ch.* [6] 10, 459). H.F. 230600 (B. a. V.); 197000 (Von Rechenberg). A starch-like substance occurring in the roots of elecampane (*Inula Helenium*) (Valentin Rose, *A. D.* 1804), dandelion (*Taraxacum dens leonis*), chicory (*Oichorium linytus*), feverfew (*Phacelium Parthenium*), and meadow saffron (*Colchicum autumnale*); in the tubers of the potato, the dahlia, and the Jerusalem artichoke (*Helianthus tuberosus*); in Lerp manna (from *Eucalyptus dumosa*), and in certain lichens (*Lichen fraxineus* and *Lichen fastigiatus*). Sinistrin, from the sea-onion (*Urginea Scilla*), is perhaps identical with inulin.

Preparation.—The finely divided roots are boiled with water in presence of a small quantity of CaCO_3 . The filtrate is cooled by a freezing-mixture, and, after thawing the ice, filtered again. The pp. is redissolved in hot water, and the filtered solution again subjected to the action of a freezing mixture, the process being repeated until the inulin is perfectly white. The inulin is then freed from traces of levulose by treatment with 97 p.c. alcohol, and is finally dried over sulphuric acid. It still, however, contains about .6 p.c. proteid matter corresponding to .1 p.c. nitrogen, and also minute traces of inorganic substances (Kiliani, *A.* 205, 147).

Properties.—White powder, resembling starch. Tasteless. Occurs also in a gum-like or horny modification, probably as a hydrate. Sl. sol. cold water, v. sol. hot water, insol. alcohol. The powder is composed of minute spheres (Sachse). It melts at 160° , becoming changed to amorphous 'pyro-inulin' (Prantl, *N. J.* 2, 19, 513, 577, 641). Inulin is very hygroscopic, and even when dried at 100° its composition appears to be $(\text{C}_6\text{H}_{10}\text{O}_5)_n \cdot \text{H}_2\text{O}$ (Kiliani). The aqueous solution of inulin does not form a jelly like that of starch. It is not coloured blue by iodine. It dissolves in cold aqueous KOH and the solution, when acidified, deposits after a while unaltered inulin. It dissolves in ammoniacal cupric oxide solution (Cramer, *J. pr.* 73, 16) the solution yielding after a few hours a copious blue pp. (Schlossberger, *J. pr.* 73, 378). It dissolves in an ammoniacal solution of nickel oxide. It does not ppt. lead acetate or subacetate, but with a solution of lead acetate containing ammonia it gives a white pp. Inulin is not ppt. by salts of Fe, Cu, Hg, Ag, or Au. Inulin forms with alkalis unstable compounds which are soluble in water and ppt. therefrom by alcohol. When carbonised it emits an odour of burnt sugar. It reduces ammoniacal gold and silver solutions, but not Fehling's solution. It is not fermentable, nor is its optio activity affected by diastase. It is not converted into levulose by invertin. A solution of inulin dissolves PbO . Baryta-water gives a pp. soluble in excess of a solution of inulin, and not decomposed by CO_2 .

Reactions.—1. When heated with water at 100° it is slowly but completely converted into levulose.—2. Boiling dilute acids quickly convert it into levulose.—3. Dilute *nitric acid* oxidises it to racemic, oxalic, glycolic, and formic acids, but forms neither saccharic nor mucic acids (Tollens, *A.* 249, 220).—4. By long contact with bromine it yields bromoform, oxalic acid, and CO_2 .—5. With bromine and silver oxide it yields glycolic acid, (from the intermediate formation of levulose).—6. When heated with baryta-water small quantities of lactic acid are formed.—7. *Sodium-amalgam* has no action on inulin.—8. With *chloro-sulphuric acid* (ClSO_3H) at 0° it forms $\text{C}_6\text{H}_4(\text{SO}_3\text{H})_6(\text{Cl})_2$ ($[\alpha]_D = +11\frac{1}{2}^\circ$) whence warm water produces levulose (Classon, *J. pr.* 128, 27).

Acetyl derivatives. These are best formulated as derivatives of $\text{C}_6\text{H}_4\text{O}_6$.

Tri-acetyl derivative $\text{C}_6\text{H}_4\text{Ac}_3\text{O}_3$. Formed by boiling inulin (1 pt.) with Ac_2O (1 pt.) and HOAc (2 pts.) for 15 minutes (Ferreouillet & Savigny, *Z.* [2] 5, 509; Lescour & Morelle,

amorphous yellowish mass, v. sol. water and alcohol, insol. ether. Laboratory.

Tetra-acetyl derivative $C_4H_4I_4O_4$. From inulin by heating with Ac_2O (F. a. S.; Schützenberger, *A.Ch.* [4] 21, 234). Amorphous. Laboratory.

Hexa-acetyl derivative $C_6H_6I_6O_6$. Amorphous. Laboratory.

Hepta-acetyl derivative $C_7H_7I_7O_7$. Dextrorotatory.

Metinulin. When inulin is heated with glycerin alone, or when it is heated with dilute acids, the product contains bodies resembling dextrin. They are not very soluble in water and on heating yield soluble metinulin and inuloid which are not so powerfully levorotatory as the unaltered inulin. Optically inactive derivatives are also formed, but they are not identical with levulosan (Hönig a. Schubert, *M.* 8, 529). Metinulin was prepared by Dragendorff by heating inulin (1 pt.) with water (5 pts.) in a closed vessel, and ppg. with alcohol. Inuloid is a similar or identical substance, said by Popp (*A.* 156, 190) to occur in the Jerusalem artichoke. It is twice as soluble in water as inulin.

INVERTIN v. FERMENTATION, vol. ii. p. 541.

IOD- or IODO-. Use of this prefix applied to inorganic compounds; for Iodo-compounds and Iodo-salts v. the element the iodo-compound of which is sought for, or the salts to the name of which iodo- is prefixed. Thus iodo-chloride of lead will be found under LEAD, and iodo-chromate of potassium under CHROMATES.

IODATES and PERIODATES. Salts of iodic and periodic acids, v. IODINE, Oxyacids of, pp. 21, 23.

IODATION v. IODO-COMPOUNDS.

IODHYDRIC ACID HI. (Hydriodic acid. Hydrogen iodide.) Mol. w. 127.53. Solidifies at -55° (Faraday, *T.* 1845, 170). V.D. 63.22. S.H.p. ($21^\circ-100^\circ$; equal mass of water = 1) .055

(Strecker, *W.* 17, 447). S.H.p. (20°) 1.397; S.H.v.

(100°) 1.396 (Strecker, *loc.*). E.C. of $HIAq$ v. Kohlrausch, *P.* 159, 233. S.G. of $HIAq$ saturated at $0^\circ=1.99$ (De Luynes, *A.Ch.* [4] 2, 385); 2.0 (Vigier, *Bl.* [2] 11, 125). Vapour-pressure of liquid HI at $-17.8^\circ=2.9$ atmos., at $0^\circ=4$ atmos., at $15.5^\circ=5.8$ atmos. (Faraday, *T.* 1845, 170; values approx. only). H.F. $[H, I] = -6036^\circ$ gaseous H and solid I to form gaseous HI ; $[H, I] = -436$ gaseous elements at 180° ; $[H, I, Aq] = -18,170$ (*Th.* 2, 35). HI does not occur in nature.

Formation.—1. By direct union of H and I , by passing a stream of H over I at a full red heat (Courtois, *A.Ch.* 85, 305; Merz a. Helzmann, *B.* 22, 869). Corenwinder passes H and I vapour over Pt black heated to $300^\circ-400^\circ$ (*A.Ch.* [8] 30, 242; 34, 77; v. also Blundell, *P.* 2, 216; Lemoine, *G.R.* 85, 34).—2. HI is formed by decomposing a metallic iodide by another acid, but a portion of the HI is generally decomposed with separation of I , and in some cases the HI reacts with the other acid, e.g. when H_2SO_4 is added to KI , SO_2 and H_2S are produced as well as HI and I . To prepare a solution of HI in water, Glover adds an exactly equivalent quantity of H_2SO_4 to BaI_2Aq , and separates from ppg. $BaSO_4$ (*P.M.* [8] 19, 92).—

3. By the reaction between Na_2SO_3 (Mène, *C.R.* 28, 478), or $Na_2S_2O_3$ (Gladstone, *P.M.* [8] 85, 845), I , and H_2O (cf. formation of HBr , vol. i. p. 532).—4. By decomposing PI_3 by water (Kolbe, *J.pr.* 15, 172; Vigier, *Bl.* [2] 11, 125; Pattenkofler, *A.* 188, 57). Risckher (*Ch.D.* 1863, 207) recommends to make PI_3 by adding P to I in CS_2 and distilling off the CS_2 .—5. Etard a. Moissan (*B.* 13, 1862) heat I with colophony.

Preparation.—1. Washed H_2S is passed into water in which a little finely-powdered I is suspended ($2H_2SAq + 2IAq = 4HIAq + 2S$); more I is added little by little, and the passage of H_2S is continued. When all the I has been added, and no brown colour is produced on shaking the liquid, the separated S is agglomerated by briskly agitating the vessel; the liquid is filtered, H_2S is removed by gently warming, and the liquid is distilled; $HIAq$ of S.G. c. 1.7 distils at $126^\circ-128^\circ$. An inverted untubulated retort with wide neck is a suitable vessel; the H_2S is passed down the neck of the retort by a tube dipping into the water in which the I is suspended. The $HIAq$ thus prepared may be used for making gaseous HI or a more conc. solution. About 2 pts. I are dissolved in the $HIAq$ made as described, and the solution is dropped from a tap-funnel on to amorphous P (in a flask) moistened with $HIAq$ of the same concentration; the HI produced is passed through a wide U-tube containing glass beads and some amorphous P moistened with $HIAq$ (to convert any I vapour into HI) [$PI_3 + 3H_2O + Aq = H_2PO_4Aq + 3HI$]. If dry HI is wished for, the gas is passed through a $CaCl_2$ (or better CaI_2) tube and then over P_2O_5 , and collected by downward displacement. If $HIAq$ is to be prepared, the gas coming from the first U-tube is passed into the tubulus of a retort, the neck of which dips a very little way beneath the surface of water kept cold by ice; this arrangement prevents the water from rushing back into the U tube. The flask containing P in $HIAq$, into which the solution of I is dropped, should be only very gently warmed for some time, as H_2PO_5 is among the first products of the reaction, and when this is heated H_2PO_4 and PH_3 are formed, the latter of which combines with HI to form PH_3I (cf. Bannow, *B.* 6, 1498).—2. L. Meyer recommends the following method of preparing $HIAq$ by the formation and decomposition by water of PI_3 (*B.* 20, 3831). 100 g. in a retort, with the neck inclined upwards, are moistened with a 10 g. water; a tap-funnel (or a funnel into the neck of which fits a glass rod) is fitted into the tubulus of the retort; 5 g. amorphous P and 10 g. water are placed in the funnel, and a single drop of this is allowed to flow into the retort; after a little a drop or two more is allowed to follow, and a little later the liquid is added in larger quantities. HI passes off, and may be collected in water as described under 1. No heating is required. If more than one drop of the P in water is added at first an explosion usually follows. The I carried over is nearly all deposited on the neck of the retort. 8. 14 pts. KI are warmed with 20 pts. I , and 1 to 1.5 pts. P with a little water (Millon, *J.Ph.* 28, 99; Roscoe, *C.J.* 13, 146).—4. Na_2SO_3 (6 pts.) is rubbed up with water (1 pt.), and after warming, I (3 pts.) is slowly added, and the

28, 478; cf. Gladstone, *P. M.* [3] 35, 345).—5. 60 g. of copaiba oil are slightly warmed in a 500 c.c. retort connected with a reversed condenser; 30 g. of I are added little by little, and the temperature is allowed to rise; after a few minutes a regular and steady stream of HI comes off; when this slackens the retort is allowed to cool somewhat, more I added, and heating is recommenced; about 145 g. HI may be obtained from 150 g. I (Bruylants, *B.* 12, 2059).

S. Kemp (*P. M.* [3] 7, 444) says that liquid HI may be prepared by placing H persulphide in one limb of a sealed tube and a little I in the other, and gently warming the persulphide; H_2S is evolved and liquefied, and the I dissolves in the liquid H_2S ; on then adding a drop of water (this is done by a special arrangement of the tube) HI is produced and liquefied; no details are given as to how the HI is separated from the H_2S .

Properties.—HI is a colourless, strongly acid gas; it is inflammable and extinguishes flame. Dry HI is unchanged when kept in closed tubes in the dark (Lemoine, *J.* 1877, 138). HI is readily liquefied (*v. c.*); liquid HI is colourless (Kemp, *P. M.* [3] 7, 444, says it is yellowish); at -55° it solidifies to a colourless, ice-like mass (Faraday, *T.* 1845, 170). Liquid HI is a very bad conductor of electricity (Bleekrode, *W.* 3, 161; Hætorf, *W.* 4, 374). HI is very soluble in water; the solution contains a strong acid; affinity of HIAq is about the same as that of HClAq (*v. Arrhenius*, vol. i. p. 82). HIAq is a colourless, strongly acid, fuming liquid; the solution saturated at 0° has S.G. 1.99 to 2.0; this solution gives off much HI when warmed to 40° – 50° . When HIAq containing more than c. 57 p.c. HI is distilled, HI is evolved until the S.G. becomes c. 1.67–1.70 when the B.P. becomes approximately constant at 127° (at 774 mm.), and the liquid contains 57.0 p.c. HI; if the original liquid contains less than 57 p.c. HI water distils over until the acid of 57 p.c. is produced, which then distils at 127° almost unchanged (Roscoe, *C. J.* 13, 160). By passing dry H through HIAq at 15° – 19° , an acid of constant concentration, 60.8 to 60.7 p.c. HI, is obtained; at 190° the constant acid contains 58.2 to 58.5 p.c. HI (Roscoe, *l.c.*). Topsøe gives the following S.G. and composition of HIAq (*B.* 3, 403; cf. Wright, *C. N.* 23, 242):—

Temp.	S.G. referred to H_2O at same temp.	P.c. HI	Temp.	S.G. referred to H_2O at same temp.	P.c. HI

HI is absorbed by charcoal; according to Favre 22,000 gram thermal units are produced for every 128 grams HI absorbed (*A. Ch.* [5] 1, 209).

Reactions.—1. HIAq is decomposed by electrolysis to HIO_3 and H (Riché, *J.* 1858, 101).

2. HI is slowly decomposed in sunlight, the decomposition proceeds without limit (Lemoine, *J.* 1877, 139). When mixed with oxygen and exposed to sunlight, even when the gases are dry, decomposition occurs, and proceeds the more rapidly the greater the mass of O (dry HCl and HBr are not decomposed under the same conditions) (Richardson, *C. J.* 51, 801). HIAq is readily decomposed with separation of I by exposure to air.—3. HI is decomposed by heat to H and I, slowly at 180° , quickly at 440° (Hautefeuille, *Bl.* [2] 7, 198); the dissociation of HI has been exhaustively studied by Lemoine (*v. Dissociation*, vol. ii. p. 400).—4. Heated with oxygen H_2O and I are formed.—5. Chlorine forms HCl and I; with excess of Cl, ICl_3 is produced; bromine reacts similarly.—6. Sulphur and selenium form H_2S or H_2Se , and iodide of S or Se (Hautefeuille, *Bl.* [2] 7, 198); in presence of water I reacts with H_2S to form HIAq and S (*v. Preparation* No. 1).—7. HI is without action on amorphous phosphorus at 100° , but with ordinary phosphorus, even at the ordinary temperature, it forms P_2I_4 . HIAq slowly reacts with excess of P to produce H_3PO_4 and PH_3 ($2P + HIAq + 3H_2O = PH_3 + H_3PO_4$) (Damoiseau, *J.* 1880, 272).—8. Conc. nitric acid decomposes gaseous HI instantaneously.—9. Conc. sulphuric acid forms I, and also SO_2 and H_2S .—10. Sulphur dioxide forms S, I, and H_2O .—11. Iodic acid reacts with HIAq to form I and H_2O .—12. Very many oxidisers separate I with simultaneous formation of H_2O ; e.g. MnO_2 , $HClO_4$, $HClO_3$, chromates.—13. Many metals form iodides and evolve H, with HIAq.—14. Metallic oxides and carbonates generally form iodides and H_2O ; metallic peroxides form the same products and also separate I.—15. HI produces pps. of iodides when added to solutions of salts of metals which form insoluble iodides, e.g. salts of Mg , Ag , Cu , Pd .—16. Potassium permanganate produces KIO_3 .—17. HI reacts with carbon compounds generally, especially with such as contain the group OH, as an energetic reducing agent (*cf.* Berthelot, *Bl.* [2] 9, 81, 175, 265).

Combinations.—1. HIAq dissolves several metallic iodides, e.g. BiI_3 , HgI_2 , PtI_4 , and PtI_2 ; some of the solutions thus formed react with alkalis and alkaline hydroxides to form salts, which are probably derived from acids containing I and the metal, whose iodide was dissolved in HI; e.g. by dissolving AuI_3 in HIAq and adding KOH the salt $KAuI_4$ is obtained; by similar reactions the salts Na_2PtI_6 , $MgPtI_6$, &c., are formed. Such reactions render it probable that HI combines with many metallic iodides, and that the products frequently react as acids; one or two such acid compounds have been isolated, e.g. $BiPtI_9 \cdot 9H_2O$ (*cf.* Bromhydric acid, Reaction 7, vol. i. p. 583; and Chlorhydric acid, Reaction 13, vol. ii. p. 8).—2. HI combines with ammonia to form NH_4I ; $[NH_4^+][I^-] = 48,462$ (*Th.* 2, 75).—3. With phosphine HI combines to form PH_4I ; $[PH_4^+][I^-] = 24,100$ (Ogier, *C. R.* 89, 705).

The solution of HI in water is attended with production of much heat $[HI, Aq] = 19,207$ (*Th.* 2,

Thomsen's measurements of the heat of solution of HIAg point to the existence of a hydrate $\text{HI} \cdot \text{H}_2\text{O}$; the results are similar to those obtained for HClAq , but cannot be represented by so simple a formula (cf. *CHLORHYDRO ACID*, vol. ii, p. 8).

The heat produced by diluting HI in $n\text{H}_2\text{O}$ with quantities of water varying from 200 to 300 H_2O is given by Thomsen as follows (*Th.* 8, 76):—

n	$[\text{HI} \cdot n\text{H}_2\text{O}, (300 - n)\text{H}_2\text{O}]$
2	6670
3	4400
5	1820
10	630
20	220
50	70
100	30

The acids HI , HBr , and HCl are very similar in their properties and reactions. All dissolve very freely in water, forming solutions of monobasic acids, the affinities of which are great and approximately equal. All combine with certain metallic haloid compounds, especially with those of Hg , Au , Pt , and Pd , to form compounds which are best regarded as distinct acids. The thermal reactions attending the syntheses of the three acids show a gradation. Thomsen (*Th.* 2, 39) gives the following data:—

X [H, X] gaseous, at 180° , from gaseous elements.
 Cl 22,153
 Br 12,413
 I — 436
 X [$\text{H}, \text{X}, \text{Aq}$]
 Cl 30,315 gaseous Cl at 19° .
 Br 32,197 } calculated on assumption that Br
 I 18,619 } and I are gaseous at 19° .

Of the three acids HI is the most easily decomposed by heat and by oxidisers (cf. *HALOGEN ELEMENTS*, vol. ii, p. 665, where HF is compared and contrasted with the other haloid acids HX).

IODIC ACID v. IODINE, *Oxyacids of*, p. 19.

IODIDES. Binary compounds of I with more positive elements, i.e. with any element except O , F , Cl , or Br . Iodides of almost all metals, and binary compounds of I with all non-metals except B , have been isolated. Most metallic iodides may be obtained by direct combination of the elements; many are obtained by heating I with metallic oxides, or by dissolving metals or their oxides in HIAg ; I reacts with alkalis as I alkaline hydroxides to form iodides and iodates. Some non-metallic iodides are formed by direct union of the elements, e.g. iodides of H , Br , Cl , Se , S , and P ; NI_3 is obtained by the reaction between I and NH_3Aq ; ClI by the reaction of AlI_3 on a mixture of CCl_4 and CS_2 . O and I combine indirectly; oxides of I are obtained by the action of oxidisers on I . The non-metallic iodides as a class are more easily decomposed by heat than the chlorides or bromides; oxide of I is much more stable than oxide of Cl , and no oxide of either Br or F has yet been isolated. If two chlorides or bromides of a specified metal are known, the more stable iodide of that metal as a general rule corresponds to the lower chloride or bromide, e.g. SbCl_3 and SbCl_5 exist, but only SbI_3 ; FeCl_2 and FeCl_3 are stable, but if

FeI_2 exists it very easily goes to FeI , and I ; similarly with CuI , which exists only in solution, and very readily parts with I becoming CuI , whereas CuCl_2 is more stable than CuCl . In their reactions with water metallic iodides are usually less easily decomposed than the corresponding bromides and chlorides. Metallic iodides as a class dissolve in water without change; some, however, form oxyiodides, e.g. SbI_3 and BiI_3 ; and some form oxides and HIAg , e.g. SnI_4 . Metallic iodides, generally speaking, are not so readily volatilised as chlorides or bromides; most of them are unchanged by heat, but some are decomposed to metal and I , e.g. iodides of Au , Pt , and Pd . As a whole, then, the metallic iodides are not so numerous or so varied in composition as the chlorides or bromides, and they are more stable towards heat and the action of water than the chlorides and bromides; they are also less easily reduced, e.g. by H or CO , than the chlorides or bromides.

The heat of formation of a metallic iodide is usually considerably less than that of the bromide or chloride of the same metal. The following data are taken from Thomsen:—

X	[Na , X , Aq]
Cl	193,020
Br	171,160
I	140,600
X	[Ca , X , Aq]
Cl	187,230
Br	165,360
I	134,940
X	[Al , X , Aq]
Cl	475,650
Br	410,040
I	318,780

The difference between the heat of formation in aqueous solution of a chloride and the analogous bromide of the same metal is approximately 21,850, and the difference in the case of a chloride and analogous iodide is approximately 52,250. Some metallic iodides exhibit differences in crystalline form and S.G.; for instance SbI_3 forms hexagonal crystals, and also exists in trigonal and in monoclinic forms; CdI_2 probably exists as a white salt S.G. 5.644 unchanged at 250° , and also as a brownish compound S.G. 4.626, which begins to change at 40° (v. vol. i. p. 656); there are also differences between BiI_3 according as it is prepared by sublimation or by ppn.

Iodides are usually decomposed when heated in Cl or Br with production of chlorides or bromides and I ; heated in HCl they generally form chlorides and HI . Heated with conc. H_2SO_4 , or conc. HNO_3 , I is separated, and SO_2 (also sometimes H_2S) or NO_2 is evolved. I is separated from iodides by the action of many oxidising agents, such as CrO_3 , ferric salts, MnO_2 , &c.

Many metallic iodides dissolve freely in solutions of the alkali iodides, frequently with formation of double iodides. An aqueous solution of KI dissolves much I , with formation of KI_3 , but the greater part of the I thus dissolved is ppt. on largely diluting the liquid. Some other periodides analogous to KI_3 are known; part of the I in such compounds is more loosely combined than the rest, and can generally be removed very readily; CuI_2 in solution, for instance,

is reduced to CuI by shaking with CS₂. Some iodides, e.g. PtI₂, HgI₂, combine with HI to form compounds which are best regarded as metallic acids (H₂PtI₆, H₂HgI₆, &c.). Some of the resemblances and differences between the three allied classes, chlorides, bromides, and iodides, are considered in the article HALOGENS, BINARY COMPOUNDS OF THE (vol. ii. p. 666).

IODINE. I. At. w. 126.53. Mol. w. 253.06 (v. infra). [113°-115°] (Stas); [114°-15°] (Ramsay a. Young, *C. J.* 49, 480): solidifies at 113.6° (Regnault, *J.* 1856. 41); (200°) (Stas); (184.35°) at 760 mm. (R. a. Y., l.c.). Sublimes *in vacuo* without melting (L. Meyer, *B.* 8, 1827). S.G. 4.917 at 40.3°, 4.886 at 60°, 4.857 at 79.6°, 4.841 at 89.8°, 4.825 at 107°, 4.804 liquid at 107°, 8.866 liquid at 151°, 3.796 liquid at 170°; ρ l. increases for 1° by .000235 (Billet, *J.* 1855. 46). V.D. c. 250°-1000° 125-127; c. 1500° 68 (v. *Properties*, p. 10). S.H. (solid 9°-98°) .05412 (Regnault, *M. Ch.* [2] 73, 1). S.H.p. for I vapour at 206°-377° (equal wt. of water = 1) .03369

• (Strecke, *W.* 17, 85); S.H.p. 1.294 at 220°-375° S.H.v.

(Strecke, *W.* 13, 20). Heat of fusion = 11,710; heat of vaporisation = 23,950 (Favre a. Silbermann, *A. Ch.* [3] 37, 461). For vapour pressures of solid I from 58° to 114°, and of liquid I from 114° to 186°, v. Ramsay a. Young, *C. J.* 49, 458. S.V.S. 25-9. S. .018 at 10°-12° (Wittstein, *J.* 1857. 123); .015 at 6.3° (Dossios a. Weith, *Z.* 1869. 579); S. in glycerin = 1. (Regarding solubility v. further under *Properties*.) The absorption-spectrum of I vapour shows numerous fine lines extending from the red to the violet. As the thickness of the layer increases absorption becomes very marked in the red; but even when the whole of the red part is obscured, the violet portion remains without bands (Plücker, *J.* 1863. 109; Thalen, *P.* 159, 503; cf. Conroy, *J.* 1876. 146; and Salet, *A. Ch.* [4] 28, 29). The emission-spectrum shows many bright lines in the yellow-green and yellow. By using an induction-current of low tension lines are seen coincident with the dark absorption lines (Salet, l.c.; Wüllner, *P.* 120, 158); at red heat a continuous spectrum is observed. I crystallises very easily from alcohol or HIAq, or by sublimation; the crystals are trimetric, $a:b:c = 4.866:1:7.824$ (Mitscherlich, *B.* 1855. 416).

Iodine was discovered by Courtois in 1811 in the mother-liquor of kelp after preparation of Na₂CO₃. Davy (*T.* 1814. 74) and Gay-Lussac (*A. Ch.* 89, 811, 319; 91, 5) showed I to be an element, and established its relationship to chlorine.

Occurrence.—Certain mineral waters contain small quantities of free I₂. According to Wanklyn (*C. N.* 54, 300), the water of Woodhall Spa, near Lincoln, is coloured slightly brown by free I. Iodides of Na and Mg, and iodate of Mg according to Sonstadt (*C. N.* 25, 196, 283, 241), occur in small quantities in sea-water; alkaline iodides are found in very many mineral waters; in the ashes obtained by burning sea-plants, and some sea-animals; and in certain specimens of Chili saltpetre, dolomite, phosphates, and some other minerals. Iodides of Hg, Ag, and Pb occur in small quantities in Mexico.

Formations.—1. By decomposing alkali iodides by MnO₂ and H₂SO₄, or by ClP or K₂Cr₂O₇ and H₂SO₄, or by NO₂.—2. By heating an acidified solution of an iodide with FeCl₃. 3. By reducing NaIO₃ by SO₂.

Preparation.—The greater part of the I of commerce is prepared from kelp, which is the product of burning sea-plants; the kelp is lixiviated with hot water, and the liquid is evaporated in successive stages until most of the salts except Na₂S, Na₂S₂O₃, and Na₂S₂O₄ have been removed. Enough H₂SO₄ is added to decompose the S compounds. After exposure to the air for some time S separates, and SH₂ and SO₂ escape. The liquid is then run off and distilled with addition of more H₂SO₄ and MnO₂, and the I is collected in a series of tubulated receivers luted one into the other. For details of manufacture v. *DICTIONARY OF APPLIED CHEMISTRY*. The I obtained as described is dried and sublimed. By slow resublimation fairly pure I is obtained, but ICy cannot thus be removed.

The chief impurities in commercial I are chlorides, water, traces of various salts, and sometimes ICy.

Stas (*Chem. Proport.* 187) gives two methods for preparing pure I:—1. KI is dissolved in its own weight of water, the solution is saturated with I (about 4 parts I are required to 1 part KI), water is added until formation of a permanent pp. begins. After settling, the liquid is poured off and shaken with $\frac{1}{2}$ of the quantity of water required to bring down all the I which can be pptd. by this method (the amount of water is determined by a preliminary experiment on a small quantity of the liquid). The separated I is washed by decantation until the washings are free from K, distilled with water from a large retort, allowed to drain, placed over dry Ca₂NO₃, which is frequently changed (all other drying materials bring impurities into the I), and finally twice distilled after mixing with 5 p.c. finely-powdered pure BaO. The last traces of H₂O and traces of HI are thus removed.—2. Iodide is prepared by adding powdered I to cold conc. NH₄Aq until the dark-brown liquid is nearly colourless; the compound is washed by decantation with cold conc. NH₄Aq until NH₄I is removed, placed on a funnel, the neck of which is drawn to a fine point, and covered with cold water. When the black colour of the compound changes to brownish, and the wash-water is coloured yellowish brown, the moist iodide is placed in test tubes its weight of water contained in a large glass balloon, and slowly heated on a water-bath to 60°-65°, when decomposition occurs with formation of crystals of I, solution of I in NH₄I₂Aq, and a white salt, which is probably NH₄IO₃. When the change seems completed the liquid is warmed to 100° for a few minutes; if the temperature is at once raised above 65° decomposition occurs very rapidly, at 100° it proceeds with explosive violence, at the ordinary temperature the change is very slow. After cooling, the solid which separates is thrown on to a funnel with drawn-out neck and washed with water; it is then distilled with water from a retort (NH₄IO₃ is not

volatilised), and the I is dried over Ca_2NO_3 , and finally by distilling with pure BaO as in 1.

Recovery of iodine from laboratory residues. Berstein (Z. 4870, 528) recommends to evaporate with excess of Na_2CO_3 , to heat the residue until it is white, to add excess of H_2SO_4 , and to pass in NO_2 gases, obtained by heating starch with HNO_3 , until all I has separated; to wash the I in cold water, dry over H_2SO_4 , and sublime slowly. The stream of NO_2 is best obtained by adding 15 grams starch to about 90 grams fairly conc. HNO_3 in a large flask (the acid must not be added to the starch, else the latter may cake on the bottom of the flask and cause it to break), heating till red fumes appear, and then removing the flame and cooling from time to time, if necessary, by cold water. If insoluble iodides, e.g. HgI_2 , are present, Henry (B. 2, 693), heats with water and granulated Zn or Fe filings, whereby soluble ZnI_2 or FeI_2 is produced. The final sublimation of the recovered I may conveniently be conducted as described by Mohr. The rim of a flat porcelain basin is ground with sand, so that the glass plate placed on the basin touches the rim in every part; the I is placed in the basin, a little finely powdered KI is strewn on the surface, the glass plate is placed in position and bound to the rim by a strip of paper, and the basin is placed on a sand-tray and very slowly heated. The process of sublimation should occupy several days. If any ICl is present it reacts with the KI to give KCl and I.

Properties.—A grayish-black, soft, solid with metal-like lustre. Perfectly pure I is described by Stas as quite black, whether solid or liquid. Only the thinnest plates of I are transparent (cf. Schultz-Sellack, P. 140, 334). I is very easily vaporised; the vapour corrodes the skin and mucous membranes; unsaturated vapour has a violet colour, saturated vapour appears deep blue in thin layers (Stas); a layer 10 centims. thick is quite impervious to light (cf. Andrews, C. N. 24, 75). I vapour shows orange-yellow fluorescence (Lommel, W. 19, 356); solid I does not fluoresce (Stokes). Crystals of I polarise light (Conroy, J. 1876, 147). I is a non-conductor of electricity (Jolly, P. 37, 420). I dissolves freely in solutions of alkaline oxides and in HIAg ; it is more soluble in solutions of NH_3 salts than in water. Dossios a. Weith (Z. 1869, 379) give the following numbers for the S. G. of I in KIAg :

P.a.		P.a.	
S.G. at 7°	I	S.G. at 7°	KI
1.0234	1.173	1.1382	8.363
1.0438	2.303	1.1637	10.036
1.0668	4.623	1.1893	11.034
1.0881	5.935	1.2110	11.893
1.1112	7.201	1.2293	12.643

I is more soluble in solution of tannic acid than in water; addition of .015 parts of the acid increases S. to .42 at c. 30°, and when 3.3 parts acid are present S. is .24 at 13° (Koller, Z. 1806, 880). I is very sol. in CS_2 , CHCl_3 , ether and alcohol, C_2H_5 and various hydrocarbons; also sol. in SO_2 (Sestini, Z. 1868, 719), and in SO_3 (Weber, J. pr. 25, 224); solutions in ether or alcohol contain HI (cf. Carles, Ph. 3, 5, 83). Addition of CS_2 to an aqueous solution of I causes withdrawal of most of the I from the water; according to Berthelot a. Jungfleisch

c. 400 parts of the I go into solution in the CS_2 for each part remaining in the water (C. R. 69, 338). Solutions of I in CS_2 , CHCl_3 , C_2H_5 and other liquid hydrocarbons are violet; solutions in ether, alcohol, and some other solvents are reddish-brown. The reddish solutions absorb light in the violet end of the spectrum up to midway between D and E; conc. violet solutions absorb the rays of mean refrangibility to the limits of the yellow and blue; very conc. solutions absorb all rays except the ultra-violet (cf. Vogel, B. 11, 919).

The at. w. of I has been determined:—1. By changing AgI into AgCl (Berzelius, P. 14, 558; Dumas, J. 1859, 3).—2. By synthesis of ZnI_2 (Gay-Lussac, A. Ch. 91, 5).—3. By synthesis of AgI (Marignac, *Mémoires. Univ. Genève*, 46, 387; *Ann. Chem. Phys.*, 46, 387).—4. By determining the quantity of KI required to ppt. a known quantity of Ag dissolved in HNO_3 (Marignac, l.c.).—5. By analysis of AgIO_3 (Stas, l.c.).—6. By determining V.D. of many binary compounds.—7. By measuring S.H. of I.

Attempts have been made to determine the mol. w. of I in solution. Paternò Nasini (B. 21, 2153) measured the lowering of the freezing-point of benzene and acetic acid produced by dissolving I in these liquids; the results point to the existence of molecules of I_2 in very dilute benzene solutions, and more complex molecules in more conc. solutions; the numbers got with acetic acid lead to a mol. w. between I and I_2 . Loeb (C. J. 53, 806) determined the vapour-pressure of I in solution in CS_2 and ether; ethereal solutions of I are reddish brown, solutions in CS_2 are violet; Loeb's results point to the mol. I_2 in red solutions, and a mol. w. between I_2 and I in violet solutions.

Determinations of the S.G. of I vapour, by Gay-Lussac, Dumas, Bineau, Deville a. Troost, up to c. 1000° gave values from 8.68 to 8.67 (calc. for $\text{I}_2 = 8.75$). V. Meyer (B. 13, 401, 1723; 14, 1458) obtained the following results:—8.86 at 293°, 8.72 at c. 586°, 6.76 at c. 842°, 5.76 at c. 1027°, 5.7 at c. 1570°. Crafts a. Meier (B. 13, 870; C. R. 92, 39) obtained similar results; the S.G. remained constant (8.8) to c. 700°, even when pressure was diminished, but decreased above that temperature, and decreased the more rapidly the more the pressure was lowered; the S.G. decreased with rising temperature rapidly to a certain point and then more slowly; at a pressure of 230 mm. S.G. became constant at 1400°–1500° and was = 4.6; at 152 mm. S.G. became constant at c. 1400°; at 76 mm. a constant value for S.G. was obtained at c. 1350°. At c. 1700° V. D. corresponds with molecular weight = I (Biltz a. Meyer, B. 23, 735). There can be little doubt that these results prove a gradual dissociation of I_2 into I (S.G. calc. for I = 4.875) (cf. *Dissociation*, vol. ii. p. 894; v. also Naumann, B. 13, 1050). The molecule I_2 is more easily dissociated than either of the molecules Br₂ or Cl₂.

The atom of I is monovalent in gaseous molecules. I acts as a non-metallic element; it is negative to all elements except O, F, Cl, and Br. I combines directly with most of the metals, and with some of the non-metals, e.g. H, Br, Cl, Se, S, and P; binary compounds of I with all non-metals except B have been isolated. I is closely related to F, Cl, and Br; the relationship is con-

sidered in the article HALOGEN ELEMENTS, vol. ii. p. 664; cf. also IODINES in this vol. p. 18.

Reactions.—1. I dissolves very slightly in water; the solution probably contains traces of HI. According to Cross & Higgins (*C. J.* 85, 235) I dissolves slightly in water at 100° in a sealed glass tube with production of a little alkaline iodide and iodate. Electrolysis of IAq yields HIO_3Aq (Biche, *J.* 1858, 101).—2. I does not react directly with oxygen, even when I and O are heated to c. 300° in presence of spongy Pt (Wehsarg, *B.* 17, 2896). Ogier (*C. R.* 86, 722) says that if I vapour and O are subjected to the silent discharge, all the oxides of I are produced.—3. *Hydrogen peroxide* produces HIAg and O, but conc. HIAg is decomposed by H_2O_2 with separation of I.—4. *Hydrogen sulphide* is decomposed by I in presence of water forming HI and S; dry H_2S does not react with I.—5. With solutions of *caustic alkalis*, I forms alkaline iodide and iodate; according to Van Deventer a Van't Hoff, KIO is also formed (the proof of this is indirect, *C. C.* 1888, 862).—6. *Ammonia gas* forms NH_4I and N_2 (v. *Combinations*, No. 2); *ammonia solution* forms NH_4IAg and N iodide. 7. When I is shaken with *lime* suspended in water, a bleaching liquid is obtained which reacts as if it contained Ca hypiodite $\text{Ca}(\text{IO})_2$ and CaI_2 (Lunge & Schock, *B.* 15, 1883).—8. I vapour heated with *oxides or carbonates of the alkaline earth metals*, in presence of oxygen yields periodates without formation of oxyiodides; with *lead oxides* various oxyiodides are produced (Cross & Sigiura, *C. J.* 83, 405).—9. I is oxidised to I_2O_5 by *nitric acid*, *chromic anhydride*, *chlorates*, and some other oxidisers.—10. In presence of water acts as an oxidiser towards some salts and other easily oxidised compounds; *arsenious oxide* and *arsenites* are oxidised to As_2O_5 and arsenates in alkaline solutions. *Sulphurous acid* is oxidised to H_2SO_4 , *sodium thiosulphide* is oxidised to $\text{Na}_2\text{S}_2\text{O}_8$ and a little NaHSO_4 (Pickering, *C. J.* 37, 128).—11. With some *carbon compounds* I reacts to substitute I for H, but the HI formed tends to reproduce the original compound, so that the reactions of I with C compounds are much less marked than those of Cl and Br.—12. I dissolved in CS_2 reacts with *ppd. arsenious sulphide* (not with *orpiment*) to give AsI_3 and S; at a higher temp. As_2S_3 and I are re-formed; by distilling As_2S_3 and I in the ratio $\text{As}_2\text{S}_3 : \text{I} = 61$ and heating the distillate in a sealed tube to 72° (AsI_3/SI_3 was obtained (Schneider, *J. pr.* [2] 86, 498).

Combinations.—No combination of I with H_2O has been isolated.—1. With most *metals*, and with many *non-metals*, especially with H, Cl, Br, S, Se, P, As. According to Holzmann (*B.* 22, 869) Na is scarcely attacked by I when the pure elements are heated to 300°. Fe and I combine by shaking Fe filings with I in presence of water; FeI_2 is produced, and also Fe_2O_3 and HI probably by the formation and decomposition of FeI_3 (Fleury, *J. Ph.* [6] 16, 523).—2. *Ammonia* forms several compounds with I; the dry gas is absorbed forming a dark-blue liquid; the volume of NH_3 absorbed varies with temperature, at 20° it corresponds to $3\text{NH}_3.2\text{I}$, at 80° to NH_3 , at 0° to $(\text{NH}_4)_2\text{I}_2$, at -10° to $(\text{NH}_4)_3\text{I}_3$ (Raschig, *A.* 241, 258; cf. Bineau, *A. Ch.* [8] 15, 80; Millon, *A.* 62, 54).

Detection and Estimation.—Free I is detected in solution by the colour which it gives to $\text{KF} \cdot \text{CHCl}_3$ and by the formation of a deep-blue col when a drop of starch-paste is added (cf. *Champ.* *Fr.* 14, 66; Mylius, *B.* 20, 688; Persoz, *C. R.* 74, 617; Duclaux, *C. R.* 74, 588; Gopp-riöder, *P.* 119, 57; Miasiwetz, *W. A. B.* 11, 181). I in soluble iodides is detected by adding a very little Cl water, or a drop of a solution NO_2 in conc. H_2SO_4 , and then a little starch paste. Iodates are reduced to iodides by SO_2 ; alkaline iodates mixed with alkaline iodides form a drop of a weak acid, e.g. tartaric, give free I. Many insoluble iodides may be converted to soluble ZnI_2 by treatment with Zn and dil. $\text{H}_2\text{SO}_4\text{Aq}$. Most non-metallic iodides are decomposed by water or caustic alkalis giving HI and alkaline iodide. I is estimated gravimetrically by ppn. AgI ; iodates are reduced by SO_2 and then $\text{ppd. by AgNO}_3\text{Aq}$. Volumetrically is estimated by titration with $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ or standard As_2O_3 dissolved in NaHCO_3Aq . The water in samples of iodine I may be determined by mixing with a weigh quantity of Hg, rubbing up with a little alcohol and carefully drying at 100°; loss of weight water (Bolley, *D. P. J.* 126, 40). The quantity I may be determined by dissolving in a conc. solution of an alkali sulphite, filtering, $\text{ppn. AgNO}_3\text{Aq}$, washing $\text{pp. with NH}_4\text{Aq}$ to remove AgCl and AgBr , boiling with H_2O containing little AgNO_3 to remove Ag_2SO_4 , washing the residual AgI , and weighing it, after drying, in the usual manner (Hesse, *A.* 122, 225).

Iodine, bromides of. Two bromides of I are known, IBr and IBr_3 , but neither has been gasified; attempts to prepare IBr , analogous to ICl , have failed (Bornemann, *A.* 189, 188). The combination of I with Br has been studied by Balard (*A. Ch.* 32, 337), Lagermark (*B.* 7, 107) and Bornemann (*A.* 189, 201).

IODINE MONOBROMIDE IBr. Formula not necessarily molecular, but probably so, from analogy to ICl which has been gasified. Prepared by heating I with rather more than the calculated quantity of Br to 25°–50° in a retort, removing excess of Br by a stream of CO_2 , and allowing to cool. Form dark-greyish, iodine-like crystals, melting at 86°; probably sublimes with only partial decomposition; smells of Br, the vapour attacks the eye and mucous membranes. The vapour appeared in thick strata (Gernez, *C. R.* 74, 1190). Soluble in alcohol, CHCl_3 , CS_2 , and other slowly decomposed by water with separation of I. Berthelot (*A. Ch.* [5] 21, 870) gives the H.F. of solid IBr from solid I and liquid Br as $\text{I} + \text{Br} = 2470$. A hydrate $\text{IBr} \cdot 5\text{H}_2\text{O}$ described by Löwig is merely a mixture of IBr and ice.

FORMING TRI-BROMIDE IBr₃. A dark-brown liquid obtained by heating excess of Br with I; soluble in water; with alkali solutions forms bromide and iodate; solution in sunlight decomposes to HBr and HIO_3 .

Iodine, carbide of, better called Carbon iodide; v. vol. i. p. 689.

Iodine, chlorides of. I combines rapidly with Cl even at -90° (Douny & Maréchal, *C. R.* 20, 813). Two chlorides of I have been isolated, ICl and ICl_3 ; ICl can be gasified without decomposition, ICl_3 decomposes when heated. Kämmerer (*J. pr.* 88, 88; cf. *B.* 8, 489, note) asserted

the probable existence of a tetrachloride ICl_4 , but the non-existence of this compound has been proved (cf. Hannay, *C. J.* 85, 189); Brenken (*B. 8*, 487) failed to procure any higher chloride by passing Cl over strongly cooled ICl_3 . By adding I to liquid Cl , Hannay (*C. J.* 85, 189) obtained a reddish liquid when the elements were present in the ratio $\text{I} : \text{Cl}$ as 5:1, but on removing pressure or raising temperature Cl was at once evolved.

IODINE MONOCHLORIDE. ICl . Mol. w. 161.9. $[\text{d}_4^{20}]$: (181.8°); S.G. $^{20}_{20}$ 3.18223 (Thorpe, *C. J.* 87, 174). H.F. $[\text{I}, \text{Cl}]$ = 2,100 (solid ICl from gaseous Cl and solid I), 6,700 (solid ICl from gaseous constituents) (Berthelot, *A. Ch.* [5] 24, 870). V.D. 80.29 at 120°, 83.2 at 512° (Hannay, *C. J.* [2] 11, 819). Absorption-spectrum of vapour v. Gernez, *C. R.* 74, 660.

Preparation.—1. By passing dry Cl over carefully dried I till liquefaction occurs and purifying by distillation with a gram or two of I .—2. By heating an intimate mixture of I with 4 parts KClO_3 and distilling the product from powdered KClO_3 ($\text{I} + 8\text{KClO}_3 = \text{KClO} + \text{KIO}_3 + \text{KCl} + \text{O}_2 + \text{ICl}$).—3. By boiling I with excess of *aqua regia*, diluting with water, shaking with ether and evaporating the ethereal liquid (Bunsen, *A.* 84, 1).

Properties.— ICl seems to exist in two forms; a reddish-brown oily liquid (Gay-Lussac, *A. Ch.* 91, 6), and a hyacinth-red solid (Schützenberger, *Z.* 5, 1). Thorpe (*C. J.* 87, 175) says that ICl remains liquid in a closed vessel for weeks even in a freezing mixture but solidifies on addition of a minute fragment of ICl_3 . If the liquid ICl is exposed to the air it solidifies after a time and is partially changed to ICl_3 and I (cf. Hannay, *C. J.* [2] 11, 815; Bornemann, *A.* 189, 183). According to Stortenbeker (*R. T. C.* 7, 152), two forms of solid ICl exist, one forming dark-red needles melting c. 27° obtained by cooling the liquid ICl to -25°, and another crystallising in dark-red plates melting at c. 14° obtained by crystallising the liquid between -10° and +5°. ICl smells of I and Cl , it attacks all mucous membranes rapidly and forms very bad sores if let fall on the skin; decolorises indigo, does not give blue colour with starch (cf. Christomanos, *B.* 9, 434). ICl dissolves in alcohol, also in HCl aq. Can be distilled with only very slight decomposition (Schützenberger, *Z.* 5, 1; cf. Bornemann, *A.* 189, 183).

Reactions.—1. *Water* decomposes ICl forming HCl , HIO , and I (Hannay, *C. J.* [2] 11, 820). According to Schützenberger (*L.c.*) a compound ICl.HCl is formed (besides H_2O and I) by the reaction of water with ICl (cf. also Trapp, *J.* 1854, 810; and Bornemann, *A.* 189, 183).—2. *Potash solution* produces KIO and KI with separation of I (*H. L.c.*).—3. *Ammonia solution* forms NH_4Cl and N iodide which combines with a portion of the NH_3 (Bunsen, *A.* 84, 1).—4. Distilled repeatedly with *potassium iodide*, KCl and I are formed.—5. Dissolves in *carbon disulphide*; when a saturated solution is distilled CCl_4 and CSCl_2 are formed (*H. L.c.*).—6. With many metals ICl reacts to form chlorides and iodides (*H. L.c.*), e.g. with Hg , Sn , Sb , Bi , Al , Mg , Na .—7. With *mercuric oxide*, *cupric oxide*, and *lead peroxide*, forms chlorides and iodides

with evolution of O and separation of I .—8. *Hypochlorites* and *chlorates* produce iodates with evolution of Cl (Henry, *B.* 8, 892).—9. *Mercuric chloride* forms a pp. of HgI_2 (Kaps, *F.* 11, 250).—10. *Stannous chloride* produces SnCl_4 and SnI_4 .

Combination.—With *hydrogen chloride* to form HCl.ICl ; a yellow, volatile, unstable compound; produced by dissolving ICl in water, extracting with ether, and evaporating (Schützenberger, *C. R.* 84, 889).

IODINE TRICHLORIDE ICl_3 . Mol. w. unknown; decomposed by heat to ICl and Cl . S.G. c. 3.1107 (Christomanos, *B.* 10, 789). $[\text{d}_4^{25}]$ (Trapp, *J.* 1854, 810); $[\text{d}_4^{30}]$ (Christomanos, *L.c.*). H.F. (Berthelot, *A. Ch.* [5] 21, 870) $[\text{I}, \text{Cl}_3]$ = 21,700 solid ICl_3 from gaseous constituents; 16,800 solid product from solid I and gaseous Cl ; $[\text{I}, \text{Cl}_3]$ = 9,500 solid product from solid ICl and gaseous Cl . According to Brenken (*B.* 8, 487) ICl_3 is partially decomposed when it is melted. Stortenbeker (*R. T. C.* 7, 152) gives M.P. as varying from 20° to 60°, but says that at pressure of 16 atmos. the M.P. is definite and = 101°.

Preparation.—1. By leading excess of dry Cl over I or ICl until yellowish-red crystals are formed, and then subliming at as low a temperature as possible in a stream of Cl (Brenken, *B.* 8, 487).—2. By the action of HCl off warm powdered HIO ; Cl is evolved (Ditte, *A.* 158, 335). 3. By the action of PCl_5 on I_2O_5 .—4. Christomanos (*B.* 10, 434, 789) recommends to lead dry Cl and dry HI into a well-cooled glass receiver, keeping the Cl in excess ($\text{HI} + 4\text{Cl} = \text{HCl} + \text{ICl}_3$; if HI is in excess the reaction $\text{HI} + \text{ICl}_3 = \text{HCl} + 2\text{ICl}$ occurs). To prepare small quantities of ICl_3 , say, in a bulb tube, Christomanos leads dry Cl through the tube, cools the place where the ICl_3 is to be deposited, then allows dry HI to stream through the tube, and finally leads dry Cl again, all parts of the apparatus being gently warmed except that where the ICl_3 is to be formed.

Properties.—A citron-yellow, crystalline, deliquescent solid. Very disagreeable smell; attacks the eyes and nose. Can be kept unchanged only in dry Cl (Hannay; Christomanos). In air sublimation with partial decomposition begins even at -12° (*C.*). Complete decomposition into ICl and Cl occurs at c. 70°-80°, even in an atmosphere of Cl at pressure of 760 mm. (Malikoff, *B.* 8, 490). According to Brenken (*B.* 8, 487) ICl_3 does not melt when heated, but decomposes even in an atmosphere of Cl into ICl and Cl at c. 25°, the temperature varying according to the pressure. ICl_3 is sol. water, with partial change to ICl , HCl , and HIO ; at 100° this change occurs suddenly and completely (Bornemann, *B.* 10, 121; Christomanos, *L.c.*). Sol. benzene, sol. *o.c.* H_2SO_4 .

Reactions.—1. With *water* to form ICl , HCl , and HIO ; in cold water a part of the ICl_3 remains unchanged; in hot water the change is complete; at 100° it occurs very rapidly.—2. With *caustic alkalis*, chloride and iodide, chlorate and iodate, of the alkali are produced (Christomanos, *L.c.*).—3. With excess of *ammonia*, NH_4Cl , NH_4I , and NI_3 are formed (*C.*).—4. *Nitric acid* produces Cl and I (*C.*).—5. *Hydrogen iodide* in excess forms ICl and HCl (*C.*).—6. *Carbon disulphide* produces some S chloride, the reaction contains

Si_2I (C.) (*cf.* Weiss, P. 128, 459).—7. Carbon dioxide passed over ICl forms a little COCl_2 (C.). 8. ICl_3Ag shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Phil. p. B. 8, 4).—9. Hydrogen has no action at the ordinary temperature; when the ICl_3 is slightly warmed HCl + I are produced; at a higher temperature HCl , HI , and I are obtained (C.).—10. Potassium and phosphorus burn in ICl_3 , forming chlorides and iodides (C.).—11. ICl_3 oxidises hot sulphurous acid solution to SO_3Ag , and hot ferrous sulphate solution to ferric sulphate (C.).—12. On carbon compounds the action of ICl_3 is to chlorinate; e.g. $\text{C}_2\text{H}_5\text{O}$, even in the dark forms $\text{C}_2\text{H}_5\text{ClO}_2$, with simultaneous production of HCl and ICl .

Iodine, cyanides of. Better called CYANOGEN IODIDE, v. vol. ii. p. 313; and CYANOGEN IODIDE, v. vol. iii. p. 320.

Iodine, fluoride of. IF_5 . A colourless, strongly smelly and fuming liquid; does not solidify at -20° ; obtained by decomposing AgF by I . Attacks glass and Si at red heat; no action on Hg or Pt ; decomposed by water to HIO_3 and HF (Gore, C. N. 24, 291; MacIvor, C. N. 32, 232).

Iodine, hydride of, y . IODHYDRIC ACID, p. 11.

Iodine, nitride of. Better called NITROGEN IODIDE (*q. v.* in this vol.).

Iodine, oxides of. The only oxide of I which has been certainly isolated is I_2O_5 ; the existence of IO_2 is probable. Other oxides have been described, but the proofs of their isolation are very meagre. I and O do not combine directly; Wehsarg (B. 17, 2896) passed I and O over spongy Pt heated to $c. 300^\circ$ without obtaining any compound. According to Ogier (C. R. 36, 722) when a mixture of I vapour and O is submitted to the silent electric discharge all the oxides of I are produced. I_2O_5 is the anhydride of HIO_3 , which acid is known as a definite stable solid; IO_2 (if it exists) is not an anhydride, it is said to combine with H_2SO_4 . The hypothetical anhydride of periodic acid, I_2O_7 , has not been isolated. The heat of formation of I_2O_5 is a large positive quantity $\approx c. 45,000$. I_2O_5 is a much more stable body than any of the oxides of Cl ; no oxide of Br or E has been isolated.

Iodine pentoxide. I_2O_5 (Iodic anhydride.) Mol. w. unknown, as oxide has not been gasified. S.G. ≈ 4.487 (Ditte, A. Ch. [4] 21, 5); S.G. ≈ 4.7987 (Kämmerer J. pr. 79, 94). C.E. $0^\circ-51^\circ$. -0.00066 . H.F. from solid I [I° , O°] = 45,029; [I° , O° , Ag] = 43,237; [I° , O° , Ag] = -1,792 (Th. 2, 164). S. = 187.4 at 18° ; S.G. of this solution = 2.1269 (Kämmerer, P. 138, 890). A white crystalline solid; crystals belong to trimetric system (Schabus, J. 1854, 210). Produced by slowly heating dry HIO_3 to 170° . Melts when heated to $c. 300^\circ$, with decomposition into I and O . When HIO_3 crystallises from solutions containing H_2SO_4 , crystals of I_2O_5 are said to accompany the HIO_3 (Rammelsberg). Sol. Crater; insol. ether, alcohol, CHCl_3 , CS_2 , or C_2H_5 (Ditte, C. R. 70, 621). I_2O_5 dissolves in water to form HIO_3 . The general reactions of I_2O_5 are those of an oxidiser: CO passed over warmed I_2O_5 forms CO_2 and I ; SO_2 gives SO_3 ; H_2S produces HI , H_2O , S , and I ; HCl forms ICl and H_2O ; NH_3 on heating gives H_2O , N , and I (Ditte, *loc. cit.*) NO

does not react with I_2O_5 (Kämmerer, J. pr. 93).

Combinations.—1. According to Kämmerer (J. pr. 33, 73) when dry SO_2 is passed over I , heated to 100° , a part of the SO_2 is oxidised to SO_3 , a little I being separated, and then a yellow crystalline compound $\text{I}_2\text{O}_5 \cdot \text{SO}_3$ is formed. As soon as the compound is formed the SO_3 must be stopped. The compound is decomposed by moisture, even by exposure to ordinary air. Ditte (C. R. 70, 621) says that in this reaction only I and SO_3 are produced. According to Web (B. 20, 87) the compound $\text{I}_2\text{O}_5 \cdot \text{SO}_3$ is formed by heating the constituents in a sealed tube at $c. 60^\circ$, and pouring off excess of SO_3 ; the compound is decomposed above 60° .—2. By heating HIO_3 slowly to $50^\circ-40^\circ$, or more quickly to 130° the hydrate $\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ is said to be formed. Ditte however, says this is only a mixture of I_2O_5 and HIO_3 .

Nitroso-derivative (?). By treating perfectly dry finely-powdered I with $c. 10$ times its weight of the most conc. HNO_3Ag , of a mixture of equal parts of conc. HNO_3Ag and H_2SO_4 , a loose flocculent yellow powder is obtained. This substance was regarded by Millon (J. pr. 34, 819) to be a compound of I , O , and HNO_3 ; according to Kämmerer (J. pr. 33, 65) it is $\text{I}_2\text{O}_5(\text{NO})_2$, but analyses are given. The substance is extremely unstable, it cannot be dried over CaO without decomposition; it is decomposed by water (HNO_3 , HIO_3 , and I). Heated in CO_2 , NO , or I_2O_5 are formed.

Iodine dioxide or tetroxide. IO_2 or I_2O_4 . This substance probably exists as a definite compound. One part of perfectly dry I is rubbed in a basin with 10–12 pts. conc. HNO_3Ag S.G. at least 1.486, until a loose flocculent yellow powder is produced (*v. supra*); excess of acid is poured off, the powder is placed in a funnel stopped with asbestos, and is then dried on porous tile, and finally over lime; HIO_3 and are then removed by washing with water and then with alcohol (Millon, J. pr. 34, 819, 837). IO_2 is described as a sulphur-yellow powder, unchanged in air, decomposed to I and HIO_3 by heating in air to $170^\circ-180^\circ$, insol. cold water but decomposed by boiling water giving I and HIO_3 , not acted on by alcohol. Warm HNO_3 produces HIO_3 and I ; but H_2SO_4 dissolves the substance, and on cooling crystals of $\text{H}_2\text{SO}_4 \cdot \text{IO}_2$ separate; HClAg forms ICl and Cl ; aqueous alkali solutions produce iodates, but alcoholic solutions of alkalis are said to form red liquid containing very unstable compounds.

Other compounds of iodine and oxygen have been described, but it is very doubtful whether any definite compound except I_2O_5 and probably IO_2 has been isolated. By the action of ozone on I , Andrews & Tait obtained a yellow powder supposed by some chemists to be I_2O (A. & T. Pr. 9, 608; no analyses given). Ogier (C. R. 35, 957) asserted the formation of I_2O by the action of ozonised O on I ; he described it as a yellow deliquescent powder decomposing at $125^\circ-130^\circ$, with evolution of I and O , giving HIO_3 and I with water. Millon (J. pr. 34, 836) supposed he had obtained I_2O by exposing to moist air the product of boiling I_2O_5 with conc. H_2SO_4 until both I and O were coming off. Kämmerer (J. pr. 33, 73) treated I_2O_5 with SO_2 and by

washing the product with water, it retained a brownish-yellow colour. Iodine and I_2O_5 . These substances give rise to Bengisser (in 1838) (A. 1838, 1839), heating H_2IO_3 (v. Periodates) in water, and that of c. 180° remains; possibly I_2O_5 may, but Ramberg (J. pr. 10, 1838) that decomposition of H_2IO_3 begins at 133°, and Lang (J. pr. 56, 36) puts the decomposition temperature at 130°.

Iodine, oxyacids of. The only oxyacids of I which are certainly known are HIO_3 and H_2IO_3 ; both are solids. There are indications of the existence of HIO in aqueous solution, but neither this acid nor any of its salts has been actually isolated. The periodic acid corresponding with $HClO_4$ has not been isolated, but many salts of the form $M^+HIO_4^-$ are known; the periodates form several complex series of salts whereas all the perchlorates belong to the series $M^+ClO_4^-$. HIO_3 is a product of the action of many oxidisers on I, e.g. HNO_3 , in presence of H_2O , KOH . This acid or an iodate is also formed by digesting MgO , HgO , or Ag_2O with I and H_2O , or by shaking up $AgNO_3$ with an alcoholic solution of I. Electrolysis of IAq or $HIAq$ yields HIO_3 . Iodides dissolved in water are oxidised by $KMnO_4$, and by bleaching powder, to iodates. HIO_3 is produced by heating solutions of $HClO_4$, $HClO_3$, $HClO_2$, or $HBrO_3$ with I. If these reactions are compared with those whereby bromic and chloric acids are obtained (vol. i. p. 537, and vol. ii. p. 15) it is seen that it is more easy to pass from less oxidised, or non-oxidised, compounds of I to HIO_3 , than from corresponding compounds of Cl or Br to $HClO_4$ or $HBrO_3$. The heat of formation of HIO_3 is much greater than that of HI , whereas the heats of formation of $HClO_4$ and $HBrO_3$ are considerably less than those of HCl and HBr :— $[H, I, Aq] = 13,170$; $[H, I, O^+, Aq] = 55,800$ (cf. vol. ii. p. 665). Periodic acid and its salts are stable compounds; they are more readily formed by oxidation processes than perchlorates, e.g. passing I vapour with O over heated BaO produces Ba periodate, and passing Cl into an alkaline iodate in presence of alkali produces an alkaline periodate. The anhydride of iodic acid, I_2O_5 , is known as a stable solid; but the anhydride of periodic acid, I_2O_7 , has not been isolated (v. *supra*, Iodine, oxides of).

Detection and estimation of iodates and periodates. Iodates are detected by mixing with an alkaline iodide, adding a little starch paste, and a few drops of a weak acid, e.g. tartaric acid, when I is set free and colours the starch blue. Periodates give a brown ppt. of $AgIO_3$ on addition of $AgNO_3$ in presence of HNO_3 . Periodates may be separated from iodates by ppg. both as Ba salts and digesting pp. with NH_4 carbonate, when Ba^+ periodate remains unchanged, but the iodide is converted into $BaCO_3$. Iodates may be estimated by reduction to iodides by means of SO_2 or SH_2 , and ppg. with $AgNO_3$; or by digesting with KI and a little HCl , when CHI_3 is set free and decomposes the KI, giving free I, which is determined volumetrically. Periodates may be estimated by a similar method (v. Kimmins, C. J. 51, 861).

Hydro-iodous acid and Hydro-iodites. Neither the acid nor any of its salts has been isolated.

IODIC ACID.

HIO_3 and I_2O_5 . This acid quickly bleaches indigo, gives a blue colour when I is decomposed by H_2O , Aq with starch, evolution of O_2 on heating, &c. formed. This solution probably contains a trace of $NaIO_3$ (Schönbein, J. pr. 84, 337; Bertius, B. 10, 337; Van Deventer, Van't Hoff, C. C. 1888, 337; Lunge, Schönbein (B. 15, 1883), by the action of I_2 on Ca suspended in water, obtained a colourless solution which bleached logwood, litmus, and cochineal; gave no colour with starch; addition of acids separated I; H_2O , Aq caused evolution of O_2 ; the solution decomposed slowly in the dark, more rapidly in sunlight, but even on boiling for some hours it was only partially decomposed. L. a. S. suppose this solution to contain an I compound, analogous with bleaching powder, probably $CaOI_2$.

Iodic acid; and Iodates. HIO_3 ; MIO_3 . The acid seems to have been first obtained by Connel by oxidising I by conc. nitric acid (New Edin. Philos. Journ. 10, 93, 337; 11, 72; 13, 284). Occurrence.—Sometimes in commercial nitric acid (Pettenkofer, J. 1857, 581). Formation.—1. By oxidising I by very conc. HNO_3 , Aq , or by $HBrO_3$, Aq (Kammerer, J. pr. 79, 94), or $HClO_4$, Aq (Davy, S. 11, 68, 234; 16, 343).—2. By decomposing $Ba(IO_3)_2$ by the proper quantity of H_2SO_4 , Aq .—3. By suspending $AgIO_3$ in water, adding an equivalent quantity of I, filtering from AgI , and evaporating to dryness ($10AgIO_3 + 12I + 6H_2O + Aq = 12HI + 10AgI + 10AgI$; Kammerer, p. 138, 390). The $AgIO_3$ is prepared by ppg. NH_4IO_3 by $AgNO_3$, and the NH_4IO_3 is made by digesting $Ba(IO_3)_2$ with solution of NH_4 carbonate.—4. By digesting an aqueous or alcoholic solution of $AgNO_3$ with I ($10AgNO_3 + 12I + 6H_2O = 10HNO_3 + 10AgI + 2HIO_3$, Aq ; Lassaigne, J. Chim. méd. 9, 508; Weltzien, A. 91, 43).—5. By decomposing KIO_3 , Aq by H_2SiF_6 , Aq , filtering, and evaporating to dryness; the product is impure.—6. By leading Cl into water containing I in suspension; the greater the dilution the greater the quantity of Cl required to change all the I into HIO_3 (cf. Bornemann, A. 189, 183; Sodini, B. 9, 1126).—7. By electrolysis solution of I or HI (Riche, C. R. 46, 848).—8. By the action of AuO_3 on I in presence of water ($6I + 5Au_2O_3 + 3H_2O + Aq = 6HIO_3 + 10Au$; Collin, G. A. 48, 280).—9. By moistening IOI with a little water and then shaking with ether or alcohol (Liebig, P. 24, 863).—10. Alkaline iodates are obtained by acting on I with caustic alkalis, or by oxidising alkaline iodides by $KMnO_4$, Aq or solution of bleaching powder (Hempel, A. 107, 100; Reinige, Fr. 9, 89; Reichardt, A. P. [3] 5, 109; $KIAq + 2KMnO_4 + H_2O = KIO_3 + 2MnO_2 + 2KOH$; $2KIAq + 6CaOCl_2$; $= Ca(IO_3)_2 + 5CaCl_2 + 2KCl$).—11. $Hg(IO_3)_2$ is obtained, along with HgI_2 , by shaking I with ppg. HgO suspended in water (Collin, G. A. 48, 280).

Preparation.—1. About 5-10 grams finely powdered I is placed in a large flask, twice its

SiO_2 (C.) (cf. Weiss, P. 128, 459).—7. Carbon dioxide passed over ICl_3 forms a little COCl_2 (C.). 8. ICl_3 shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Philipp, B. 3, 4).—9. Hydrogen has no action at the ordinary temperature; when the ICl_3 is slightly warmed HCl and ICl are produced; at a higher temperature HCl , H_2O , and HIO_3 are obtained (C.).—10. Potassium HIO_3 . The phosphorus burn in ICl_3 is poured off, the semi-iodides (C.) are separated to dryness in a basin, and the remaining acid is removed either by repeated evaporations with water or by heating to 100° – 180° in an air-current. The crystalline mass may be dissolved in water and slowly evaporated to the crystallisation-point, and the crystals heated to 170° .—2. Two pts. conc. H_2SO_4 and c. 8 pts. water are added to 9 pts. finely powdered $\text{Ba}(\text{IO}_3)_2$, the whole is boiled for half-an-hour; after settling, BaSO_4 is removed by filtration, and the filtrate is evaporated until HIO_3 separates on cooling; the crystals are dissolved in water, a very little $\text{Ba}(\text{IO}_3)_2$ is added, and the liquid is evaporated and filtered. Stas says that pure HIO_3 cannot be obtained by this method; the crystals always contain either $\text{Ba}(\text{IO}_3)_2$ or H_2SO_4 . The $\text{Ba}(\text{IO}_3)_2$ required may be prepared: (1) by adding BaCl_2 to NaIO_3 obtained by passing Cl into water containing I in suspension, till the I is all dissolved, then adding Na_2CO_3 till neutral, and again passing in Cl (Liebig, P. 24, 363); (2) by suspending I in hot saturated BaOAc and passing Cl into the liquid (Kämmerer, J. 1860, 94); (3) by adding rather more than the equivalent quantity of I to hot conc. KClO_3 and then a few drops of nitric acid, Cl is freely evolved, and KIO_3 crystallises on cooling, the salt is recrystallised once and decomposed by BaCl_2 Aq.—3. NH_4IO_3 is prepared by digesting $\text{Ba}(\text{IO}_3)_2$ with NH_4 carbonate solution, filtering, and crystallising; AgNO_3 Aq is added to a solution of the NH_4IO_3 , and the AgIO_3 obtained is collected and washed; the AgIO_3 is suspended in water and I is added in the ratio of 1 gram to 1.857 grams of the AgIO_3 ; the reaction $10\text{AgIO}_3 + 12\text{I} + 6\text{H}_2\text{O} = 12\text{HIO}_3 + 10\text{AgI}$ proceeds when the liquid is warmed on the water-bath; AgI is removed by filtration and the liquid is evaporated to dryness and the residue heated to c. 170° (Kämmerer, P. 138, 390).

Properties.— HIO_3 forms colourless trimetric crystals; $a:b:c = 589:11:1903$ (Rammelsberg, P. 90, 12); $a:b:c = 9388:1:13181$ (Schabus, J. 1854, 810). It is doubtful whether HIO_3 shows dimorphism or not (v. Rammelsberg, *Handbuch der Krystallographischen Chemie*, i. 41). Thomsen gives the following thermal data (Th. 2, 163):— $[\text{H}, \text{I}, \text{O}] = 57,963$; $[\text{HIO}_3, \text{Ag}] = -2,166$; $[\text{IO}_3^-, \text{H}^+] = 2,540$. S.G. 2.4629 (Ditte, C. R. 70, 621). Very soluble in water; most conc. solution, according to Kämmerer, contains 68.51 p.c. HIO_3 , boils at 100° , and has S.G. 2.1629. Kämmerer gives the following table:—

S.G. at 14°	P.c. HIO_3	S.G. at 14°	P.c. HIO_3
1.0058	1.65	1.4428	36.89
1.0268	5.27	1.5371	42.16
1.0525	10.54	1.6315	46.98
1.1228	15.51	1.7356	52.70
1.2098	21.08	1.8689	57.97
1.2778	26.86	1.9954	63.24
1.3484	32.62	2.1269	68.51

does not react with I_2O_5 the volume-change is $\frac{1}{10}$ Aq. He expresses

Combinations.—1. $\text{Acid} + 89 \left(1 - \frac{a}{a+18}\right)$; (J. pr. 38, 72) when dry, heated to 100° , a part of solution is represented SO_3 , a little I being a volume of one molecule crystalline compound taken as 18. For optical upon as the compound crystals v. Lang, W. A. B. 31. The compound 1625 (Ditte, A. Ch. [4] 21, 52). Electrolysis of HIO_3 produces I and O (Magnus, P. 102, 1; Buff, A. 110, 257).

Reactions.— HIO_3 reacts as an energetic oxidiser. 1. Most non-metals are oxidised by HIO_3 Aq; e.g. P to H_3PO_4 , As to H_3AsO_4 , B to HBO_3 , Si at 250° to SiO_2 (Ditte, Bl. 1870, 318); S , Se , and C are oxidised by heating in sealed tubes with HIO_3 Aq, S to H_2SO_4 , Se to H_2SeO_4 , gas coke at 180° and anthracite at 210° to CO_2 ; diamond is not acted on.—2. All metals, except the Pt metals and Au, are oxidised by HIO_3 Aq.—3. Sulphurous acid is oxidised to H_2SO_4 ; sulphuretted hydrogen to S and HI ; the lower oxides of nitrogen to HNO_3 .—4. Hydrochloric acid forms ICl and Cl .

Combinations.—1. With water to form $2\text{HIO}_3 \cdot 9\text{H}_2\text{O}$; obtained by cooling saturated HIO_3 Aq to -17° .—2. With sulphuric acid; by dissolving HIO_3 in hot conc. H_2SO_4 , and cooling, crystals of $2\text{HIO}_3 \cdot 3\text{H}_2\text{SO}_4$ are said to be obtained; the mother-liquor deposits other compounds of the two acids; if $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ is used crystals of $3(\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}) \cdot 2\text{HIO}_3 \cdot 2\text{H}_2\text{O}$ are formed; these compounds are decomposed by water (Millon, J. pr. 34, 321). Crystalline bodies, supposed to be compounds (Davy), are obtained by mixing conc. HIO_3 Aq with solutions of H_3PO_4 and HNO_3 .

Basicity and formula of iodic acid.— HIO_3 is generally looked on as a monobasic acid, analogous to HClO_3 and HBrO_3 . Besides the normal K salt there exist two acid salts, KHI_2O_6 and $\text{KH}_2\text{I}_2\text{O}_6$; there are no chlorates or bromates similar to these. Iodic acid is easily decomposed by heat to water and the anhydride I_2O_5 ; such a reaction does not usually occur with monobasic acids. Iodic acid is isomorphous with the dibasic acids, succinic and itaconic. The chlorates and bromates as a class are easily soluble in water; the iodates are very slightly soluble. The thermal phenomena attending the formation of the three acids, HClO_3 , HBrO_3 , and HIO_3 , mark off HIO_3 from the two others, thus:—

$[\text{HCl}, \text{Aq}] = 39,320$	$[\text{HClO}_3, \text{Aq}] = 23,940$
$[\text{HBr}, \text{Aq}] = 23,380$	$[\text{HBrO}_3, \text{Aq}] = 12,420$
$[\text{HI}, \text{Aq}] = 13,170$	$[\text{HIO}_3, \text{Aq}] = 65,800$

The heat of formation of the acid HX decreases as the atomic weight of X increases, whereas in the series of oxyacids the heat of formation decreases from Cl to Br , but then increases very largely from Br to I . A similar variation is shown in the R salts, thus:—

$[\text{KCl}] = 105,810$	$[\text{KClO}_3] = 95,840$
$[\text{KBr}] = 95,810$	$[\text{KBrO}_3] = 84,062$
$[\text{KI}] = 80,180$	$[\text{KIO}_3] = 124,489$

The iodates are not generally isomorphous with the chlorates and bromates. Thomsen says the only case of isomorphism is presented by the Ba salts. There is no doubt that the constitution of periodic acid is very different

from that of perchloric acid. Thomsen shows some fairly marked differences in boiling acid. Thus, if one dissolves alcohol in this H_2O , (228 grams) is dissolved, give rise, in this case, to a solution of the iodine in the acid, the volume of the solution is 1500.2 c.c.; the molecular weight of iodine acid is taken as H_2O , and this quantity (352) is dissolved in 80 H_2O , the volume of the solution is 1440 + 59.9 = 1499.9 c.c. In other words, one molecular proportion of H_2O , dissolved in 80 molecular proportions of water, produces the same expansion of the liquid as is produced by one molecular proportion of iodic acid, provided the formula of this acid is taken to be H_2O . The foregoing are the chief arguments brought forward by Thomsen for establishing a difference between the constitutions of iodic acid on the one hand and chloric and bromic acids on the other hand, and for showing that iodic and periodic acids are closely related (*Th.* 2, 168-223).

The heats of neutralisation of HClO_4 , HBrO_3 , and HIO_3 are practically identical (*Th.* 1, 242). When NaOHaq is added to NaIO_3 a very small quantity of heat is developed, about 4 p.c. of the total heat of neutralisation; but the reaction of NaOH with the monosodium salt of an undoubted dibasic acid is always accompanied by the production of as much, or nearly as much, heat as attends the addition of the first molecular weight of NaOH to the acid. If iodic acid is regarded as dibasic, then the salt KH_2IO_6 must be looked on as either a compound of the normal salt K_2IO_6 with $2\text{H}_2\text{IO}_3$, ($2\text{KH}_2\text{IO}_6 = \text{K}_2\text{IO}_6 + 2\text{H}_2\text{IO}_3$), or as the acid salt of a hypothetical acid H_2IO_6 .

On the whole there appear to be marked differences between the oxyacids of I and those of Cl and Br. The oxyacids of I form more complex salts than those of the other halogens. The constitution of the iodates and periodates cannot be settled by defining the basicities of the acids HIO_3 and H_2IO_4 . Several series of periodates certainly exist, and there is probably more than a single series of iodates.

The salts KHI_2O_6 and $\text{KH}_2\text{I}_2\text{O}_6$ may of course be formulated as $\text{K}_2\text{O} \cdot 2\text{I}_2\text{O}_5 \cdot \text{H}_2\text{O}$ and $\text{K}_2\text{O} \cdot 3\text{I}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ respectively.

IODATES. These salts are formed by neutralising HIO_3 by bases, or in some cases by oxidising I in presence of a base (e.g. *Iodic acid, Formation*, Nos. 10 and 11), or by double decomposition from the alkali iodates. The iodates are generally insoluble or slightly sol. in water; the alkali iodates are readily soluble. KIO_3 , however, is only slightly soluble (S. at $20^\circ \text{C} = 8$). The iodates are decomposed by heat, generally giving a mixture of metallic iodide and oxide, sometimes iodide only. Solutions of iodates are more easily reduced than chlorates; reduction of $\text{KIO}_3 \cdot \text{Aq}$ is brought about by $\text{SO}_2 \cdot \text{Aq}$ or $\text{SH}_2 \cdot \text{Aq}$; with HIAq iodates give I and metallic iodide; with HClAq they give IOCl_2 , Cl_2 , H_2O , and metallic chloride; dilute H_2SO_4 produces HIO_3 .

The following are the chief memoirs on igloos; they are referred to by numbers in the following descriptions:—(1)^a Bell, J. 1871. 298: (2) Berthelot, C. Ammonium iodate NH_4IO_3 . Lustrous plates decompose at 150° ; S. 2.6 at 15° , 14.5 at 100° . S.G. 3.31-3.34. Formed by action of NH_3 on HIO_3 or HIO_4 on NH_3 or $(\text{NH}_4)_2\text{CO}_3$ (4, 24, 28).

Barium iodate $\text{Ba}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$. By dissolving I or ICl_3 in BaO aq; or by pptg. NaIO_3 aq b BaCl_2 or $\text{Ba}(\text{NO}_3)_2$. Lustre is monoclinic crystals which lose H_2O at 130° , and when strongly heated form Ba periodate $\text{Ba}_2\text{I}_2\text{O}_8$. S.G. 5.18-5.28. S. 0.7 at 135° ; 1.5 at 100° (4, 8, 10, 12, 13, 16, 18, 24, 27).

Calcium iodate $\text{Ca}(\text{IO}_3)_2$. Occurs in sea water. Formed by adding $\text{CaCl}_2\text{Aq.}$ to $\text{KIO}_3\text{Aq.}$ or $\text{HIO}_3\text{Aq.}$ to $\text{Ca}(\text{NO}_3)_2\text{Aq.}$ By action of bleach-
ing powder on KIO_3 crystallises with $6\text{H}_2\text{O}$, and
from $\text{KIO}_3\text{Aq.}$ + $\text{Ca}(\text{NO}_3)_2\text{Aq.}$ with $4\text{H}_2\text{O}$ (Flight).
Efflorescent rhombic crystals; on heating gives
mixture of CaO and Ca periodate; v. insol.
water (6, 18, 18, 24, 27).

Copper iodates.—1. $\text{Cu}(\text{IO}_3)_2 \cdot 2\text{H}_2\text{O}$; greenish-blue pp. by mixing conc. NaIO_3 aq and CuSO_4 aq; salt with H_2O remains on warming. S. 53 col. 65 at 100° .—2. $3\text{Cu}(\text{IO}_3)_2 \cdot 3\text{Cu}_2\text{O} \cdot 2\text{H}_2\text{O}$; by action of HIO_3 aq on strongly-heated CuO . By dissolving (1) in NH_4aq the compound $\text{Cu}(\text{IO}_3)_2 \cdot 4\text{NH}_3 \cdot 3\text{H}_2\text{O}$ is formed (18).

Mercury iodate $\text{Hg}(\text{IO}_3)_2$. By warming freshly pptd. HgO with HIO_3Aq , or adding HIO_3Aq to $\text{Hg}(\text{NO}_3)_2\text{Aq}$ or $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ (not by adding HIO_3 to HgCl_2). White powder; insol. water (3).

Potassium iodate. Normal iodate KIO_3 . Prepared by dissolving I in KOH Ag, evaporating to dryness, and dissolving out KI by alcohol S.G. '81; also by passing Cl into I suspended in water, neutralising by KOH Ag and evaporating. Stas adds 1½ pts. KClO_3 to semi-fluid KI in a crucible, dissolves, on cooling, in hot water, and recrystallises the KIO_3 , which separates (8, 16, 17, 28). Crystallises in cubical forms. S.G. 4.875; KIO_3 Ag S.G. 1.0741 at 19°5' contains 9.08 KIO_3 to 100 water (13). S. at 5° 5.8, at 9° 5.67, at 24° 7.7, at 22° 2-9.2, at 45° 8-16.6, at 69° 27 (8). Insol. alcohol S.G. '81. Poisonous. Decomposes, at higher temperature than KClO_3 , to KI and O_2 without production of KIO_4 ; heated with MnO_2 forms I_2O_5 and K_2O (8, 24, 25). KIO_3 Ag shaken with finely-divided Fe gives KI (21). From solution in hot dilute H_2SO_4 Ag rhombic crystals of $2\text{KIO}_3 \cdot \text{H}_2\text{O}$ separate, which lose H_2O at 190° (6). The double salt $\text{KIO}_3 \cdot \text{KHSO}_4$ is obtained by heating KIO_3 in large excess of dilute H_2SO_4 Ag, evaporating at 25° until KHSO_4 crystallises out, and further

AgI (O.) (*cf.* Weiss, P. 128, 459).—7. Carbon dioxide passed over AgI forms a little COCl_2 (O.). 8. ICl_2Ag shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Philipp, B. 3, 4).—9. Hydrogen has no action at the ordinary temperature; when the ICl_2 is slightly warmed HCl + ICl are produced; at a higher temperature H_2O + a double is obtained (O.).—10. Lined by heating KIO_3 + phosphorus humus + HCl , or by adding to ICl_2Ag less than enough KOH to saturate it (c. ratio $\text{KOH} : 2\text{ICl}_2$) and allowing to evaporate (16, 24, 26). 8. Tri-iodate KHI_3O_8 (or $\text{K}_2\text{O} \cdot 3\text{I}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$). Formed by adding a large excess of HIO_3Ag to KIO_3Ag and evaporating; also by heating KIO_3 with large excess of dilute H_2SO_4 and evaporating at 25° . Large transparent triiodine crystals; lose all H_2O at 200° . S. 4 at 15° (6, 16, 24, 26). Berthelot (2) describes a basic iodate $\text{KIO}_3 \cdot \text{K}_2\text{O}$ obtained by heating KI in O_2 .

Silver iodate AgIO_3 . Formed by ppg. AgNO_3Ag by HIO_3Ag or NaIO_3Ag . Crystallises from NH_4Ag in monoclinic crystals. S.G. 5.4. Soluble without decomposition in dilute HNO_3Ag (4, 14, 16, 24, 28).

Sodium iodate NaIO_3 . Prepared by saturating 10 pts. water holding 1 pt. I in suspension, with Cl , neutralising by Na_2CO_3 , again passing Cl , again neutralising by Na_2CO_3 and passing Cl , and so on; finally the solution is evaporated to $\frac{1}{10}$ th its bulk and mixed while warm with half its volume of alcohol; the crystals which separate are pressed and washed with alcohol till free from NaCl (15). Crystallises at under 5° with $2\text{H}_2\text{O}$, above 5° with H_2O ; at 70° crystals of $\text{NaIO}_3 \cdot 6\text{H}_2\text{O}$; hydrates with 8, 6, and 3 H_2O are also described (6, 18, 24). S. 2.52 at 0° , 3.3.9 at 400° (18). Loses O and I when heated (15). According to Rammelsberg (24), a compound of NaI with Na_2O ($6\text{NaI} \cdot \text{Na}_2\text{O}$) remains on heating NaIO_3 . With conc. HCl Ag , Cl is evolved, and a compound of HIO_3 and NaCl remains (6). Double salts with NaI are obtained by evaporating mixtures of NaIO_3Ag with NaIAg ; $\text{NaI} \cdot \text{NaIO}_3 \cdot 8\text{H}_2\text{O}$, $\text{NaI} \cdot \text{NaIO}_3 \cdot 10\text{H}_2\text{O}$, and $8\text{NaI} \cdot 2\text{NaIO}_3 \cdot 20\text{H}_2\text{O}$ are described (6, 15, 19, 24). The existence of acid iodates is denied (6, 32; *cf.* 18, 22, 26).

Besides the foregoing iodates, the following have been prepared:— $\text{Cd}(\text{IO}_3)_2$ (24); $\text{Co}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ and $\text{Co}(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$ (4, 24); various Fe iodates (1, 5, 24); $\text{Pb}(\text{IO}_3)_2$ (23, 24); $\text{Mg}(\text{IO}_3)_2 \cdot 4\text{H}_2\text{O}$ (6, 16, 18); $\text{Ni}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ and $\text{Ni}(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$ (4, 24); $\text{Sr}(\text{IO}_3)_2$ (24); $\text{Zn}(\text{IO}_3)_2 \cdot 2\text{H}_2\text{O}$. Iodates of Al , Bi , Ce , Cr , Di , Au , La , Li , Mn , Sr , Sn , U , Y , and Zn also seem to exist, but they have not been fully investigated.

Periodic acid and periodates.—The only acid which has been isolated is H_5IO_6 ; but at least five distinct series of periodates are known. The anhydride of periodic acid has not been obtained; when the acid is heated it loses H_2O , O , and I , and iodic anhydride, I_2O_5 , remains; Bengieser in 1886 (4, 17, 254) stated that by heating periodic acid to 180° it lost water of crystallisation, and that O comes off rapidly at 180° ; but according to Rammelsberg (J. pr. 103, 278) and Langlois (J. pr. 56, 86) decomposition begins at a 186° .

does not react with I_2O_5 (14); they prepared H_5IO_6 .

Combinations.—1. Acid cold water, where heated to 100° , a part of the action of I on SO_2 , a little I being set free (P. 188, 404, 410). Crystalline compound, $\text{Na}_2\text{H}_2\text{IO}_6$, is prepared by the compound of equal parts NaIO_3 and HIO_3 concentrating, and allowing to crystallise (P. 188, 404, 410). This process is also used for $\text{Na}_2\text{H}_2\text{IO}_6$ and $\text{Na}_2\text{H}_2\text{IO}_6$; the latter is more soluble and may be removed by long-continued washing with cold water (Kimmerling, C. J. 51, 357), but it is not necessary to do this in preparing H_5IO_6 . The Na salt dissolved in water with addition of just enough HNO_3 to form a clear solution, and AgNO_3Ag added; a brown pp. of Ag_2HIO_6 is thus obtained (Kimmerling, C. J. 51, 357; former observers said that Ag_2IO_6 or $\text{Ag}_2\text{H}_2\text{IO}_6$ is produced). The brown Ag salt is suspended in water, and shaken with Br ; AgBr ppts., and H_2O , along with HBrO_3 , goes into solution; the filtrate is evaporated to the crystallising point, whereby HBrO_3 is decomposed, and is then placed over H_2SO_4 in *vacuo* (Kimmerling, P. 188, 390).—2. Ag_2HIO_6 prepared as described in 1 is dissolved in conc. HNO_3Ag , and the solution is evaporated at 100° , orange-red crystals of $\text{AgIO}_3 \cdot \text{H}_2\text{O}$ separate; by treatment with cold water this salt decomposes to $\text{H}_2\text{IO}_6\text{Ag}$ and $\text{Ag}_2\text{I}_2\text{O}_8 \cdot 8\text{H}_2\text{O}$ which may be again converted into AgIO_3 by solution in conc. HNO_3Ag and evaporation (Magnus, A. Ammermüller, P. 28, 514).—3. $\text{Na}_2\text{H}_2\text{IO}_6$ prepared as described in 1, and mixed with $\text{Na}_2\text{H}_2\text{IO}_6$, is dissolved in as little dilute HNO_3Ag as possible, $\text{Pb}(\text{NO}_3)_2\text{Ag}$ is added, the pp. of Pb periodate ($\text{Pb}_2(\text{IO}_6)_3$, Kimmerling) is digested with rather less dilute $\text{H}_2\text{SO}_4\text{Ag}$ than suffices to decompose it all, and the liquid is filtered and evaporated (Bengieser, A. 17, 254).

Properties.— H_5IO_6 crystallises in transparent, colourless prisms, probably monoclinic (Rammelsberg). M.P. 183° (Rammelsberg, J. pr. 103, 278), 180° (Langlois, J. pr. 56, 86); melting is accompanied by partial decomposition (Bengieser, A. 17, 254, put the temperature of decomposition at 180°). H_5IO_6 does not lose weight at 100° , nor by keeping over H_2SO_4 . Very deliquescent; fairly sol. in alcohol; slightly sol. in ether. Thomsen (B. 7, 71; Th. 2, 427) gives the following data for S.G. and expansion of $\text{H}_5\text{IO}_6\text{Ag}$:

Ratio of H_5IO_6 to H_2O	S.G. of solution	Expansion for each formula-weight of acid
$\text{H}_5\text{IO}_6 \cdot 20\text{H}_2\text{O}$	1.4008	59.77
" 40 "	1.2165	59.80
" 80 "	1.1121	59.99
" 160 "	1.0570	60.2
" 320 "	1.0288	60.0

The volume when H_2O is present is expressed by the formula $V_a = 18a + 59.8$. The following thermal data are taken from Thomsen (Th. 2, 166):— $[\text{H}_5\text{IO}_6] = 135,780$; $[\text{H}_5\text{IO}_6\text{Ag}] = -1880$; $[\text{I}_2\text{O}_5\text{Ag}] = 27,000$. $\text{H}_5\text{IO}_6\text{Ag}$ exposed to air becomes yellow, and smells strongly of ozone.

Reactions.— $\text{H}_5\text{IO}_6\text{Ag}$ reacts as an energetic oxidiser; with HCl it gives Cl and HIO_3 (M. A. L.); with P and Bi it forms P_2O_5 and Bi_2O_3 .

(Kammerer, *loc. cit.*); O_2 v. (2). Other acids are oxidised by iodine, and HI are also oxidised; boiling alcohols at HI form ZnO , Fe_2O_3 , Hg give rise, in this case, the iodine dis-
tively (Bengieser, *loc. cit.*).
PERIODATES. Most of the penultimate soluble in water; they are isopropyl from the Na or K salts by heating; many of them are decomposed by heat giving O and metallic iodides, e.g. KIO_3 , $AgIO_3$; others evolve O and I , and leave either oxide, e.g. salts of Ni and Mg, or a mixture of oxide and iodide, e.g. salts of Pb, Cu, Cd; Hg salts give iodide and Hg; NH salts decompose explosively to I , N , O , and H_2O . Very many periodates are known; they may be divided into several classes; the following scheme presents the chief classes and the chief salts in each class. The nomenclature is that adopted in Gmelin-Kraut's *Handbuch*. All the acids except H_5IO_6 are hypothetical; formulas of salts are given here without water of crystallisation.

does not act on stylyl-p-toluidine (*B. 11*, 107).
8. By heating chloro- compounds with fuming HNO_3 (Lieben, *Z.* 1868, 712).—9. Nitrogen iodide, acting on dilute alcoholic solutions of the potassium derivatives of phenols, forms iodo-phenols and ammonia (Willgerodt, *J. pr.* [2] 87, 446).

Reactions.—1. The displacement of iodine by chlorine. Iodine may be effected by heating

FeH_2IO_3	ortho	$Pb_2H_2IO_3$
$Pb_2H_2IO_3$		$Ag_2H_2IO_3$
$Ag_2H_2IO_3$		CdH_2IO_3
CdH_2IO_3		$Ag_2H_2IO_3$
$Ag_2H_2IO_3$	meso	$Ag_2H_2IO_3$
Ni_2IO_3		

When a salt is obtained by ppn. from a acidified solution of an alkali salt, the series to which the ppd. salt belongs is conditioned by the relative quantity of acid present; thus when $AgNO_3$ is added to a solution of $Na_2H_2IO_3$, K_2L_2O or KIO_3 , acidified by a little HNO_3 , $Ag_2H_2IO_3$ is obtained; when more HNO_3 is present the pp. is $Ag_2H_2IO_3$; and when conc. acid is present

$Ba_2I_2O_6$
 $Ag_2I_2O_6$

Primeso-periodates
derived from H_5IO_6
($3H_5IO_6 - 10H_2O = H_3I_3O_9$)

$Ba_3I_3O_9$
 $Sr_3I_3O_9$

The series to which a periodate belongs seems to depend partly on the nature of the base, and to a large extent on the conditions of preparation. By neutralising H_5IO_6 by $NaOH$ Ag Rammeberg (*P.* 184, 368, 449) obtained $NaIO_3$; by neutralising the same acid by various carbonates the following salts have been obtained:—

Ortho-series	Dimeso-series	Meta-series	Di-series
BeH_2IO_3	$Ca_2I_2O_6$	$Cd(IO_3)_2$	$Mg_2I_2O_6$
	$Cu_2I_2O_6$	$Mg(IO_3)_2$	$Zn_2I_2O_6$
	$Mg_2I_2O_6$	$Sr(IO_3)_2$	
	$Zn_2I_2O_6$		

By passing Cl into a hot mixture of KIO_3 and KOH , KIO_3 , K_2L_2O , and $K_2H_2I_2O_6$ are produced; but the Na salts formed under similar conditions are $Na_2H_2IO_3$, $Na_2H_2IO_3$, $Na_2I_2O_6$, and perhaps $NaIO_3$. By heating $Ba(IO_3)_2$ the salt

sent the salt $AgIO_3$ is obtained. Boiling salts of the ortho-, meso-, or dimeso- series with HNO_3 as a rule produces salts of the meta- series. Acid salts of the ortho- series are changed to normal salts of the meso- or dimeso- series by heating, and acid salts of the meso- series are changed to normal salts of the dimeso- series; thus $Pb_2H_2(IO_3)_2$ at 275° gives $Pb_2(IO_3)_2$ and H_2O , and $Ag_2H_2IO_3$ gives $Ag_2I_2O_6$ and H_2O at 300° . Some of the periodates show very distinctly the difference between so-called 'water of crystallisation' and 'water of constitution'; thus $Ag_2H_2IO_3$ (which might be written $Ag_2I_2H_2O_6$) and $Ag_2I_2O_6$ (which also might be written $Ag_2I_2H_2O_6$) are quite different bodies; the change $2Ag_2H_2IO_3 = Ag_2I_2O_6 + H_2O$ occurs at 300° , but $Ag_2I_2O_6$ loses H_2O at 130° ; again $Ag_2H_2IO_3$ (which might be written $Ag_2I_2H_2O_6$) is a dark-red pp., obtained by adding $AgNO_3$ to $Na_2H_2IO_3$ in a slight excess of HNO_3 , Ag .

H_2I_2 (O). (cf. Weiss, P. 128, 459).—7. Carbon dioxide passed over H_2I_2 forms a little COCl_2 (C). 8. ICl_2Ag shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Philipp, B. 3, 4).—9. Hydrogen has no action at the ordinary temperature; when the ICl_2 is slightly warmed HCl + ICl are produced; at a higher temperature periodates, v. Kinnear, v. O., 182. Thomsen (Th. 1, 244) has determined the heat of neutralisation by KOH of H_2IO_3 with the following results:—

	$[\text{H}_2\text{IO}_3\text{Ag} + \text{KOH}]_{\text{aq}}$	diff.
1	5,180	
2	26,590	21,440
3	29,740	3,150
5	82,040	2,800

From these results Thomsen concludes that H_2IO_3 is dibasic, but that basic salts are produced when more than 2KOH reacts. To explain the existence of many of the periodates, Thomsen prefers to double the formula of the acid and to represent it as normally tetrabasic, thus $\text{H}_4\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$; he classifies the chief periodates as follows:—

Normal salts.

Basic salts.

The existence of undoubted acid salts, i.e. salts in which the H is not combined with O in the form of H_2O , militates against the classification of Thomsen. The reaction of KOH with $\text{H}_2\text{IO}_3\text{Ag}$ is almost certainly a complex occurrence.

In the following description of periodates only one or two salts in each series are described in detail.

The following are the principal memoirs on periodates; they are referred to in the following paragraphs by numbers: (1) Atterberg, J. 1873. 257; (2) Bengieser, A. 17, 250; (3) Blomstrand, B. 3, 817; (4) Fernlund, J. 1867. 165; (5) Groth, P. 184, 536; (6) Kimmins, C. J. 51, 356; 55, 148; (7) Langlois, J. 1852. 345; (8) Lautsch, J. pr. 100, 65; (9) Magnus a. Ammermüller, P. 23, 514; (10) Philipp, B. 3, 4; (11) Rammelsberg, P. 44, 545; 46, 159; 62, 416; 90, 12; 115, 584; 125, 147; 134, 368, 499; 137, 805; (12) Ritter, Gm.-Z. (8th ed.), 1 [2] 805.

Ortho-series; salts derived from H_2IO_3 .

Barium orthoperiodate $\text{Ba}_2(\text{IO}_3)_4$. Prepared by heating $\text{Ba}(\text{IO}_3)_2$ in a current of dry air (Sigiura a. Cross, C. J. 85, 118); by passing I vapour and dry air over heated BaO (S. a. C.); by heating BaI_2 in a current of dry air so long as I is given off (S. a. C.). Insol. water; sol. HNO_3Ag ; heated in H gives BaI_2 and BaO .

Silver orthoperiodates.—1. AgIO_3 : said to be ppd. as a brown salt by adding AgNO_3Ag to a neutral solution of an alkaline periodate, also by shaking $\text{Ag}_2\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ with cold AgNO_3Ag (11); Kimmins (6) failed to obtain this salt; sol. in HNO_3Ag and in NH_4Ag .—2. $\text{Ag}_2\text{H}_2\text{IO}_7$: dark-red pp. by adding AgNO_3Ag to $\text{Na}_2\text{H}_2\text{IO}_7\text{Ag}$ or $\text{K}_2\text{I}_2\text{O}_7\text{Ag}$ in slight excess of HNO_3 (6).—

does not react with I_2O_5 (cf. pp. by 54). For $\text{K}_2\text{I}_2\text{O}_7\text{Ag}$ in press.

Combinations.—1. AgIO_3 (6). (J. pr. 38, 72) when dry AgIO_3 and $\text{Na}_2\text{H}_2\text{IO}_7$ heated to 100° , a part of the salts formed by Ag_2SO_4 , a little I being set free, solution of equal weights crystalline compound; the second salt is less soluble than the compound from which it may be separated by continued washing with small quantities of cold water (6).

For descriptions of the other salts of series v. (1) for Ba salt, (6) for Cu and Fe salts, for Hg salt, (11) for Ca, Sr, and Zn salts (for mps of salts, v. p. 28).

Meso-series; salts derived from hypothetical H_2IO_4 .

Barium mesoperiodate $\text{Ba}_2(\text{IO}_4)_2 \cdot 6\text{H}_2\text{O}$. ppd. the corresponding K salt by Ba_2NO_3 (11).

Potassium mesoperiodate $\text{K}_2\text{IO}_4 \cdot 4\text{H}_2\text{O}$. KI is prepared by saturating with Cl a saturated solution of equal weights of KIO_3 and KOH , a repeatedly crystallising; the salt is dissolved in water and the solution is ppd. by alcohol (11).

Silver mesoperiodate (acid salt) Ag_2HIO_4 . A dark-brown pp. by ppd. $\text{Na}_2\text{H}_2\text{IO}_7$ or $\text{K}_2\text{I}_2\text{O}_7$ just enough dilute HNO_3Ag to form a solution (6).

For description of other salts of this series (formulas given on p. 23), v. (6) for salts of I and Ni, and (11) for salts of Cd (crystallises with $5\text{H}_2\text{O}$) and Sr.

Dimeso-series; salts derived from hypothetical $\text{H}_4\text{I}_2\text{O}_7$.

Barium dimesoperiodate $\text{Ba}_2\text{I}_2\text{O}_7$. Obtained by ppn. from alkali periodates in presence of HNO_3 . By neutralising $\text{H}_2\text{IO}_3\text{Ag}$ by BaOAg , salt with $7\text{H}_2\text{O}$ is obtained, which loses $4\text{H}_2\text{O}$ at 100° , and on strongly heating goes to Ba_2IO_7 (11, 7, 8).

Ferric dimesoperiodate (acid salt) $\text{FeH}_2\text{I}_2\text{O}_7$. By ppd. solution of $\text{Na}_2\text{H}_2\text{IO}_7$ or $\text{K}_2\text{I}_2\text{O}_7$ by FeCl_3Ag and drying at 100° . Boiling with dilute HNO_3Ag does not change this salt (6).

Potassium dimesoperiodates $\text{K}_2\text{I}_2\text{O}_7$ and $\text{K}_2\text{HI}_2\text{O}_7$. Both salts are obtained by passing Cl into KIO_3 mixed with KOHAg (6). If equal weights of the KIO_3 and KOH are used, and the KIO_3 which separates is removed by filtration, the filtrate on concentration gives $\text{K}_2\text{I}_2\text{O}_7$; if this filtrate is exactly neutralised by HNO_3 , the salt $\text{K}_2\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ (v. also 11) crystallises out without concentration; if excess of HNO_3 is used, $\text{K}_2\text{HI}_2\text{O}_7$ is obtained. A solution of KIO_3 to which KOH is added is said to give triclinic crystals of $\text{K}_2\text{I}_2\text{O}_7 \cdot 9\text{H}_2\text{O}$ on concentration (5, 9). $\text{K}_2\text{I}_2\text{O}_7$ is soluble in KOHAg ; S. 10-3 cold water; solution has alkaline reaction; Cl led into boiling $\text{K}_2\text{I}_2\text{O}_7\text{Ag}$ produces KIO_3 ; with I, KI and KIO_3 are produced; strongly heated leaves $2\text{K}_2\text{K}_2\text{O}$ (11).

Silver dimesoperiodates $\text{Ag}_2\text{I}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$. Light-yellow crystals, obtained by treating $\text{AgIO}_3 \cdot \text{H}_2\text{O}$ with cold water (6, 9). Heated to 100° for 12 hours claret-coloured crystals of $\text{Ag}_2\text{I}_2\text{O}_7 \cdot \text{H}_2\text{O}$ are formed; and when the temperature is raised to 180° and kept there for many hours a chocolate-coloured powder, $\text{Ag}_2\text{I}_2\text{O}_7$, remains (6). When $\text{Ag}_2\text{I}_2\text{O}_7$ is treated with NH_4Ag , $\text{Ag}_2\text{I}_2\text{O}_7$ is produced (11).

For descriptions of other salts of this series

IODO-ALIPHONIC ACID.

21

(formulae given on p. 23) v. (9). Crystallises with 7 and 9 H₂O for Ni and Zn, (7) for Sr, and (8) for Ba. (8) and (9) for Na give rise, in this H₂O, and (11) for salts of the iodine dis-9H₂O, Cu (with 6H₂O), Mg, and penn. Meta-series; salts derived isopropyl

tical HIO.
Ferric metaperiodate Fe₂(IO₆)₃. Low, produced by boiling FeH₂IO₆ for some time with conc. HNO₃ Aq (8).

Potassium metaperiodate KIO₄. Prepared by saturating with Cl a boiling conc. solution of equal parts KIO₃ and KOH, cooling, and crystallising repeatedly from water (6, 7, 9, 11). S. 35 cold water; almost insol. KOH Aq. KIO₄ Aq shows acid reaction. At 800° forms KIO₃, decomposed by I at 160°. Reduced in solution by KI to KIO₃ and I, which is then oxidised to KIO₄ (8, 9, 10).

Silver metaperiodate AgIO₄. By dissolving Na₂H₂IO₆ or Na₂H₄IO₆ or K₂L₂O₆ in conc. HNO₃ Aq and adding AgNO₃; also by treating Ag₂H₂IO₆, Ag₂H₄IO₆, or Ag₂L₂O₆ with conc. HNO₃ Aq and evaporating on steam-bath. Orange-coloured crystals. Crystals are AgIO₄.H₂O; heated to 180° for 6 hours AgIO₄ remains as a bright-yellow powder (6). Decomposed by water giving Ag₂L₂O₆.3H₂O (11).

For descriptions of other salts of this series (formulae given on p. 23) v. (11) for salts of Ba, Cd, Ca, and Sr (crystallises with 6H₂O), (5), (7), (8), (9), and (11) for salt of Na (crystallises with 2 and 3 H₂O).

Di-series; salts derived from hypothetical H₂L₂O₆.

Cadmium diperiodate Cd₂L₂O₆.3H₂O. By ppg. a slightly acidified solution of NaIO₃ by a soluble Cd salt (11).

Silver diperiodate Ag₂L₂O₆. By treating Ag₂L₂O₆ with NH₄Aq (8, 11).

For descriptions of the other salts of this series (formulae given on p. 23) v. (11) for salt of Cu (crystallises with H₂O and 7H₂O), (11) for salt of Mg (with 6 and 9 H₂O), (11) for salt of Hg (cf. 8), (7) for salt of Zn (cf. 11).

Dimeso-di and Tri-meso series; salts derived from hypothetical H₂L₂O₆ and H₃L₃O₉ respectively; v. (8) and (11).

Iodine, phosphides of, better called **Phosphorus iodides**; v. PHOSPHORUS.

Iodine, selenides of, better called **Selenium iodides**; v. SELENIUM.

Iodine, silicides of, better called **Silicon iodides**; v. SILICON.

Iodine, sulphides of, better called **Sulphur iodides**; v. SULPHUR.

Iodine, tellurides of, better called **Tellurium iodides**; v. TELLURIUM.

iodo-ACETIC ACID C₂H₃IO₂. M. M. P. M. CH₂ClCO₂H. Mol. w. 186. [623].

Formation.—1. By digesting bromo-acetic ether with KI and alcohol, for about two hours in the dark, distilling off the resulting iodo-acetic ether and decomposing it with baryta-water (Pekin a. Dappa, P. M. [4] 18, 54).—2. By boiling Ac₂O with iodine and acetic acid (Schützenberger, J. pr. 107, 108).—3. By the oxidation of iodo-acetic aldehyde (Chantard, A. Ch. [6] 16, 152).

Does not act on ethyl-p-toluidine (B. 11, 107).—

By heating chloro-compounds with fuming HNO₃ (Lieben, Z. 1868, 722).—9. Nitrogen iodide, acting on dilute alcoholic solutions of the potassium derivatives of phenols, forms iodo-phenols and ammonia (Willgerodt, J. pr. [3] 87, 446).

Reactions.—1. The displacement of iodine by chlorine. Iodo-acetic acid may be effected by heating BAA; crystalline, decomposed by H₂O, Sn, aqueous solution by alcohol.—PbA; in solution it easily splits up into PbI₂ and glycolic acid.

Methylether MeA'. (170°). Pungent liquid (Aronstein a. Kramps, B. 14, 604).

Ethylether EtA'. (180°). From bromo-acetic ether, KI, and alcohol (P. a. D.). Also from chloro-acetic acid, KI, and alcohol (96 p.p.) by heating on the water-bath in the dark. Easily obtained by heating chloro-acetic ether with CaL₂3Aq at 75° (Spindler, A. 231, 272). Pungent heavy oil. Decomposed by EtI at 230° giving acetic ether and ethylene iodide (Aronstein a. Kramps, B. 13, 489; 14, 604). With Me₂S it forms MeS.CH₂.CO₂H and dimethyl S(CH₂.CO₂H)₂.

Chloro-ethyl ether Cl.CH₂.CH₂.O.CO.CH₂I. S.G. 1.954. From chloro-ethyl chloro-acetate by gently heating with an alcoholic solution of NaI (Henry, C. R. 97, 1308). Very pungent oil. Turns brown in daylight.

Propyl ether PrA'. (198°). S.G. 1.679. From propyl chloro-acetate and alcoholic NaI (Henry, C. R. 100, 114). Pungent oil.

Amide CH₂L.CO.NH₂. [158°]. Formed from methyl iodo-acetate and alcoholic NH₃ (Henry). Also from chloro-acetamide and alcoholic KI, by standing a few days in the cold (Menschutkin a. Jermolajeff, Z. 1871, 5). Small needles or prisms.

Nitrile CH₂L.CN. Iodo-acetonitrile. [187°]. S.G. 1.2307. From chloro-acetonitrile and alcoholic NaI (Henry, C. R. 103, 413). Colourless, very pungent oil, which becomes brown in daylight. V. sol. alcohol and ether. Slightly decomposed on distillation, with liberation of some iodine and HCl. AgOAc forms CH₂(OAc).CN.

Di-iodo-acetic acid CHL₂.CO₂H. Formed by heating di-bromo-acetic ether with KI, converting the resulting di-iodo-acetic ether into a Ca salt with milk of lime, and adding HCl (Perkin a. Duppa, C. J. 13, 1). Crystalline sulphur-yellow compound, volatile in the cold, al. sol. water. Does not blister the skin. The K and Na salts are deliquescent.—BAA; trimetric crystals, giving off iodine when heated.—CaA; silky yellow needles.—PbA; crystalline pp.—AgA; yellow crystalline powder.

Ethylether EtA'. Formed by treating di-chloro-acetic ether with CaL₂3Aq at 75° (Spindler, A. 231, 273). Formed also by adding iodine to a solution of diazo-acetic ether in ether (Curtius, J. pr. [2] 88, 433). Oil, volatile with steam; reddens on exposure to air.

Amide CH₂L.CO.NH₂. [150°]. Formed by the action of iodine upon a cold alcoholic solution of diazo-acetamide (Curtius, B. 18, 1385). Formed also by the action of conc. NH₄Aq upon di-iodo-acetic ether. Greenish-white prisms (from hot water); v. al. sol. water. Very stable towards acids and alkalis.

I_2 and I (C). (cf. Weyl, P. 128, 459).—7. Carbon dioxide passed over I_2 forms a little COCl_2 (C).—8. ICl_3 shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Phillips, B. 5, 4).—9. Hydrogen has no action at the ordinary temperature; when the I_2 is slightly warmed $\text{HI} + \text{I}_2$ are produced; at a higher temperature and water (60 C.), on leaving the closed flask to stand for about a week (in summer). Water (500 c.c.) is then added, when the iodo-acetic aldehyde separates as an oil (Chautard, A. Ch. [6] 16, 145; C. R. 102, 118; C. N. 54, 87; cf. W. P. Bloxam & E. F. Herroun, C. N. 53, 301; 54, 133).

Properties.—Limpid colourless oil, unflammable. Blackens rapidly when exposed to light. Its vapour is excessively irritating. Cannot be distilled even *in vacuo*. Decomposes at 80°. Miscible with alcohol, ether, chloroform, and CS_2 . Sol. water. Forms a crystalline hydrate. Forms a crystalline compound with NaHSO_4 .

Reactions.—1. Dilute aqueous KOH forms iodoform. Conc. KOH resinsifies it.—2. Ammonia either aqueous or alcoholic forms ammonium iodide and various bases, e.g. oxytrialdine ($\text{C}_4\text{H}_9\text{N}_3\text{O}_2$).—3. Chlorine and bromine at ordinary temperatures displace iodine giving chloro- and bromo-acetic aldehydes and resins. 4. All mineral acids decompose iodo-acetic aldehyde.—5. Reducing agents (Na amalgam, Zn and HCl) remove the iodine.—6. Oxidation with HNO_3 yields $\text{CH}_3\text{I.CO}_2\text{H}$ (82°).—7. NaOEt and KOEt yield only resinous matters.—8. Silver acetate yields acetic ether (74°).—9. AgCN gives $\text{CH}_3\text{CN.CO}_2\text{H}$.—10. AgSCN similarly gives $\text{CH}_3\text{SCN.CO}_2\text{H}$.—11. The amines form crystalline bases with elimination of water. Thus aniline gives $\text{CH}_3\text{I.CH(NH}_2\text{C}_6\text{H}_5)_2$, and *p*-toluidine gives $\text{CH}_3\text{I.CH(NH}_2\text{C}_6\text{H}_4)_2$.

Tri-iodo-acetic aldehyde CI_3CHO . Iodal (above 200°). From chloral or bromal and HI (Bertrand, J. 1881, 588).

iodo-aceto-acetic ether

$\text{CH}_3\text{CO.CHCl.CO}_2\text{Et}$. S.G. $\frac{1}{4}$ 1.7053. From cupric aceto-acetic ether and iodine in ether (Schönbrodt, A. 253, 178). Yellowish oil; v. sol. ether. Begins to decompose at 25°. AgCl gives chloro-aceto-acetic ether. AgCy gives di-oxy-terephthalic ether dihydride. AgNO_3 forms nitro-aceto-acetic ether. Reduced silver gives di-acetyl-fumaric ether. Sodium aceto-acetic ether in benzene forms di-acetyl-succinic ether.

iodo-acetone $\text{C}_2\text{H}_3\text{IO}$ i.e. $\text{CH}_3\text{CO.CH}_2\text{I}$. S.G. $\frac{1}{4}$ 2.17. Formed by the action of KI on chloro-acetone (Glutz & E. Fischer, J. pr. [2] 4, 52). Prepared by mixing acetone (200 c.c.) with iodine (100 g.) and iodic acid (40 g.), and, after a week, boiling for three hours, adding water (500 c.c.), drying the separated oil over CaCl_2 , and distilling *in vacuo* in the dark (De Clermont & Chautard, C. R. 100, 745). Very pungent oil. Not inflammable. Decomposes slowly in sunlight, but more rapidly when heated. Reduces Fehling's solution. Mineral acids convert it into $\text{CH}_3\text{I.CO}_2\text{CH}_2\text{I}$. Silver chloride forms chloro-acetone. KOAc gives $\text{CH}_3\text{CO.CH}_2\text{OAc}$.

Di-iodo-acetone $\text{C}_2\text{H}_2\text{I}_2\text{O}$ i.e. $\text{CH}_2\text{I.CO}_2\text{CH}_2\text{I}$ (62°) (M. Simpson, J. pr. 102, 880; O. Völker, A. 192, 90).

does not react with H_2 (96 g.) at 68°. As soon as released it is cooled. The oil that

Combinations.—1. From acetone (48 g.), water (96 g.) and I_2 (96 g.) at 68°. As soon as released it is cooled. The oil that (J. pr. 83, 72) when dried to the air till crystals separate these are recrystallised from heated to 100°, a part of $\text{CH}_3\text{I.CO}_2\text{CH}_2\text{I}$ and aqueous SO_2 , a little I being crystalline compound, white needles. Violently attacks glass as the compound is. Decomposed when heated. Soluble in chloroform, CS_2 , or alcohol. Sol. benzene, v. sol. ether and acetone. Cannot be distilled undecomposed.

Reactions.—1. Silver chloride gives solid $\text{CH}_3\text{Cl.CO}_2\text{CH}_2\text{Cl}$ [43°].—2. Decomposed by cold KOH, and by boiling K_2CO_3 .—3. Not converted into acrolein or acrylic acid by Ag_2O , AgCy , or HgO .—4. HgI_2 forms aceto-iodo-acetone, HI , and acetic acid, but no acrolein.—5. Zinc and acetic acid reduce it to acetone.

iodo-acetophenone

$\text{C}_6\text{H}_5\text{I.CO}_2\text{CH}_3$ [79°]. Obtained by diazotising *p*-amido-acetophenone, and heating the diazo-chloride with excess of HI (Klingel, B. 18, 2692). White flat needles or plates. Easily sol. alcohol and ether, and to a certain extent in hot water. By CrO_3 it is easily oxidised to *p*-iodo-benzoic acid [266°].

iodo-acetothienone v. iodo-thienyl methyl ketone

iodo-acetylene $\text{HC}\equiv\text{CI}$. Formed by passing a current of steam through a solution of barium iodo-propargylate ($\text{C}_3\text{I}_2\text{CO}_3$)₂ Ba (Baeyer, B. 18, 2274). Crystalline solid. Sol. water. Volatile with steam. Very poisonous. It gives a purple-red pp. with ammoniacal Cu_2Cl_2 , which is soon converted by an excess of the copper solution into copper-acetylene and cuprous iodide. It soon polymerises on keeping.

Di-iodo-acetylene $\text{ICl}_2\text{C}\equiv\text{CI}$ [78°]. Formed by the action of iodine upon acetylene-silver. By treatment with an excess of ammoniacal Cu_2Cl_2 it is converted into copper-acetylene and cuprous iodide. It readily polymerises (Baeyer, B. 18, 2275).

Di-iodo-diacetylene $\text{ICl}_2\text{C}\equiv\text{C}\equiv\text{CI}$ [101°]. Colourless crystals. Odour resembling iodoform. Formed by the action of a solution of iodine in aqueous KI upon silver-diacetylene. By treatment with an excess of ammoniacal Cu_2Cl_2 it yields copper-diacetylene and cuprous iodide. It explodes violently on heating, with a brilliant red flash. It soon polymerises on keeping (Baeyer, B. 18, 2276).

iodo-acetylene carboxylic acid v. iodo-propionic acid

iodo-acids v. Iodo-compounds.
iodo-acrylic acid $\text{C}_3\text{H}_3\text{I.CO}_2\text{H}$. Large, colourless, four-sided prisms [65°]; or plates [148°]. Easily soluble in water, alcohol, and ether. Formed by the addition of HI to propiolic acid (Bandrowski, B. 15, 2703; Stolz, B. 19, 542). The Pb and Ag salts are white crystalline fns.

α -Di-iodo-acrylic acid $\text{CHI.CO}_2\text{CH}=\text{CHI}$ [106°]. Formed by treating propiolic acid with an ethereal solution of iodine (Homblka & Stolz, B. 18, 2284). Colourless prisms, or long needles. Volatile with steam. Easily soluble in alcohol, ether, and hot water.

β -Di-iodo-acrylic acid $\text{I.C}\equiv\text{C.CO}_2\text{H}$ [183°]. Formed by addition of HI to iodo-propionic acid

IO-COOH (Homolka & Stolz). Prisms. Easily soluble in iodine and tolerably in hot water, giving alcohols at Not volatile with steam. Tri-iodo-acrylic acid (the iodine dis- Formed by the action of I_2 on penultimate iodine upon iodo-propionic acid gives isopropyl molka & Stolz, B. 18, 2286). are formed by prisms. Easily soluble in H_2O on the water, insoluble in cold water.

iodo-di-allyl-acetic acid $\text{C}_6\text{H}_{11}\text{IO}_2$, i.e. $\text{Cl}(\text{C}_6\text{H}_5)_2\text{CO}_2\text{H}$. Iodo-octinoic acid. From $\text{Cl}(\text{OH})(\text{C}_6\text{H}_5)_2\text{CO}_2\text{H}$ and fuming HIAq (Schatzky, J. B. 17, 78). Crystals; insol. water, v. sol. alcohol and ether. Easily decomposes.

iodo-allyl-alcohol $\text{C}_3\text{H}_5\text{IOH}$. [160°]. Produced by the action of aqueous I_2 on di-iodo-propyl alcohol (Hübner & Lellmann, B. 13, 460). Needles. Highly volatile with steam. Insol. water, sol. alcohol, chloroform, KHSO_4 . Not attacked by AgO .

iodo-allylene C_3H_4 i.e. $\text{CH}_2=\text{C}(\text{I})=\text{CH}_2$ (?). (98°). S.G. 1.7. From silver-allylene and iodine in KIAq (Kiebertmann, A. 135, 270). Pungent oil. Almost insol. alcohol. With zinc and HCl it gives off allylene. Combines with iodine (1 mol.).

Iodo-allylene $\text{CH}_2\text{I}_2\text{CH}_2$. Propargyl iodide. (116°). S.G. 2.077. From propargyl bromide and alcoholic NaI (Henry, B. 17, 1132). Liquid. V. e. sol. alcohol and ether, m. sol. boiling water. Readily combines with iodine, forming colourless needles of $\text{CHI}:\text{ClCH}_2\text{I}$ [41°]. Combines with mercury.

iodo-allylene iodide v. Tri-iodo-propylene.

tri-iodo-allyl ethyl oxide $\text{C}_6\text{H}_9\text{IO}_3$ i.e. $\text{Cl}_2:\text{C}(\text{IOH})_2\text{OEt}$. From the silver derivative of propargyl ethyl oxide and iodine in ethereal solution (Liebertmann, A. 135, 285). Oil.

di-iodo-allyl-iodide v. Tri-iodo-propylene.

tetra-iodo-di-allyl phosphite $(\text{CHI}:\text{ClCH}_2\text{O})_2\text{P}(\text{OH})$. [49°]. From propargyl alcohol, iodine, and red phosphorus (Henry, B. 8, 893; 17, 1133). Long slender needles (from alcohol). Very pungent.

iodo-amido-benzoic acid $\text{C}_7\text{H}_5\text{INO}_2$, i.e. $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO}_2\text{H}$ [8:2or6:1]. [137°]. Formed by reducing iodo-nitro-benzoic acid [265°] dissolved in glacial acetic acid (Grothe, J. pr. [2] 18, 326). Dark brown crystals. V. sol. water. By further reduction it forms *o*-amido-benzoic acid [143°].— HA^+HCl .— BaA^+ .

Iodo-amido-benzoic acid $\text{C}_7\text{H}_5(\text{NH}_2)\text{CO}_2\text{H}$ [8:2or2:1]. [209°]. From iodo-nitro-benzoic acid [174°]. Needles, sl. sol. water. May be reduced to *o*-amido-benzoic acid. $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO}_2\text{H}$.— KA^+ .— BaA^+ .

di-iodo-m-amido-benzoic acid $\text{C}_7\text{H}_4(\text{NH}_2)_2\text{CO}_2\text{H}$. Formed together with $\text{N}(\text{C}_6\text{H}_5)_2\text{CO}_2\text{H}$, by treating an alcoholic solution of *m*-amido-benzoic acid [173°] with iodine and mercuric oxide (Benedikt, B. 8, 384). The acids are separated by fractional ppn. of their alcoholic solution by lead acetate. Long needles. Decomposed by heat. Insol. water, v. sol. alcohol, ether, aqueous acids, alkalis, and Na_2CO_3 .— KA^+ : long silky needles, obtained by mixing alcoholic solutions of the acid and KOH .

Does not act on *o*-styryl-*p*-toluidine (B. 11, 107).—
8. By heating chloro-compounds with fuming HIAq (Lieben, Z. 1869, 712).—9. Nitrogen iodide, acting on dilute alcoholic solutions of the potassium derivatives of phenols, forms iodo-phenols and ammonia (Willgerodt, J. pr. [2] 37, 448).

Reactions.—1. The displacement of iodine by chlorine or bromine may be effected by heating needles, sol. hot water. AgA^+ .

DI-iodo-*p*-AMIDO-PHENOL

$\text{C}_6\text{H}_3(\text{NH}_2)\text{OH}$. [222°]. Formed by reducing the corresponding nitro-phenol with SnCl_2 and HCl (R. Seifert, J. pr. [2] 28, 437). Needles (from alcohol) or plates (from MeOH). With HCl and bleaching powder it gives di-iodo-quinone chlorimide (q. v.). With H_2SO_4 and $\text{K}_2\text{Cr}_2\text{O}_7$ gives di-iodo-quinone (q. v.).— B^+HCl . Decomposed by water.

iodo-amido-phenol

$\text{C}_6\text{H}_4(\text{NH}_2)\text{OH}$ (6:5:2:1:4). From the oxim of iodo-thymoquinone by reduction with SnCl_2 (Kehrmann, J. pr. [2] 89, 392). Its stannochloride forms large colourless prisms.

iodo-amido-toluene sulphonic acid

$\text{C}_7\text{H}_5\text{MeI}(\text{NH}_2)\text{SO}_3\text{H}$ [1:4:2:5]. Formed from the corresponding nitro-toluidine sulphonic acid by diazotisation and treatment of the product with conc. HIAq at 135° (Foth, A. 230, 808). Slender silky needles (from water). V. sl. sol. cold water.

iodo-AMYL ALCOHOL $\text{C}_5\text{H}_{11}\text{IO}$ Amylene glycol iodhydrin. Formed by shaking up amylenes with iodine, water, and HgO (Lippmann, Z. 1867, 17; A. Suppl. 5, 124). Heavy oil, decomposed by distillation.

iodo-AMYLIDENE-ANILINE

$\text{C}_6\text{H}_4\text{I}:\text{CH}:\text{NC}_6\text{H}_5$. Formed by heating iodo-isovaleric aldehyde with aniline (Chautard, A. Ch. [6] 16, 168). Yellow prismatic needles of rectangular tables. Decomposed by heat. V. sol. alcohol, sol. water and ether, v. sl. sol. benzene and chloroform. With HCl it forms an uncrystallisable salt.

***o*-iodo-ANILINE** $\text{C}_6\text{H}_4\text{IN}$ i.e. $\text{C}_6\text{H}_3(\text{NH}_2)$

[1:2]. Mol. w. 219. [56.5°]. Formed by heating at 100° a mixture of *o*-iodo-nitro-benzene (25 pts.) with ferrous sulphate (250 pts.) and a moderate excess of dilute ammonia. The product is extracted with ether, the extract distilled with steam, the product dissolved in dilute H_2SO_4 , freed from iodo-nitro-benzene by shaking with ether, ppd. by ammonia, and the iodo-aniline again distilled with steam (Rörner & Wender, G. 17, 486). Long silky needles, with an odour resembling pyridine. Sl. sol. hot water, v. sol. other solvents. Exhibits an alkaline reaction. Turns brown on exposure to air and light. Decomposes when heated, evolving iodine. Iodine converts it into di-iodo-aniline [96°].

Salts.— B^+HCl aq: small prisms or cubes, turning opaque on exposure, with loss of water of crystallisation.— $\text{B}^+(\text{H}_2\text{SO}_4)_2$: silky needles, m. sol. water. Nitrate: small four-sided tables. Acetyl derivative $\text{C}_6\text{H}_3(\text{NHAc})_2$. [110°]. Prisms or hexagonal tables; m. sol. hot water, v. sol. alcohol.

***m*-Iodo-aniline** $\text{C}_6\text{H}_4(\text{NH}_2)$ [1:3]. [27°]. Formed by reducing *m*-iodo-nitro-benzene (Griess, Z. 1866, 218). Silvery plates.

Acetyl derivative $\text{C}_6\text{H}_3(\text{NHAc})_2$. [119.5°].

I_2 (C). (cf. Weber, P. 128, 459).—7. Carbon dioxide passed over ICl_2 forms a little COCl_2 (C).
 8. ICl_2 shaken with silver oxide forms AgCl and HIO_3 , heated with excess of Ag_2O , Ag periodate (Phillips, B. 8, 4).—9. Hydrogen has no action at the ordinary temperature; when the ICl_2 is slightly warmed HCl + ICl are produced; at a higher temperature H_2 (Hofmann, Ber. 64). Prisms or needles; heavier than water.

Has no action on litmus. Sl. sol. cold water; v. sol. other solvents. Bromine converts it into tri-bromo-aniline. — B^1HCl : thin laminae or needles (from hot water); sl. sol. cold water, almost insol. HClAq ; sol. alcohol, insol. ether. — $\text{B}^2\text{H}_2\text{PtCl}_6$: orange pp. — $\text{B}^3\text{H}_2\text{C}_2\text{O}_4$: long needles, sl. sol. water and alcohol, insol. ether. — $\text{B}^4\text{H}_2\text{SO}_4$: scales.

Acetamide derivative $\text{C}_6\text{H}_4\text{I}(\text{NHAc})$. [183°]. S. (alcohol of 95 p. cent.) in small quantities on tables or trimetric prisms. — B^1HCl : by dissolving acetanilide in glacial acetic acid and passing in vapour of iodine chloride, the yield being 85 p. (Michael & Norton, Am. 1, 255).

Benzoyl derivative $\text{C}_6\text{H}_4\text{I}(\text{NHbz})$. [180°]. Long needles (Hübner, B. 10, 1717). An isomeride [210°] is formed from benzanilide and ICl_2 .

Di-iodo-aniline $\text{C}_6\text{H}_3\text{I}_2(\text{NH}_2)$. [4:2:1]. [96°]. Formed by the action of iodine on phenylated 'white precipitate' NHPb.HgCl (Rudolph, B. 11, 78). Formed also by passing ICl (2 mols.) into a solution of aniline in HOAc (Michael & Norton, Am. 1, 255; B. 11, 109). Needles. Sl. sol. boiling water and ligroin, v. sol. ether, chloroform, CS_2 , acetic ether, and hot alcohol. Volatile with steam. It is slightly basic, but its hydrochloride is decomposed by cold water. — B^1HCl : long white needles, decomposed at 50°. — $\text{B}^2\text{H}_2\text{PtCl}_6$. — B^3HNO_3 . — $\text{B}^4\text{H}_2\text{SO}_4$.

Benzoyl derivative $\text{C}_6\text{H}_3\text{I}_2(\text{NHbz})$. [181°]. Slender needles (Rudolph).

Tri-iodo-aniline $\text{C}_6\text{H}_2\text{I}_3(\text{NH}_2)$. [6:4:2:1]. [185-5°]. Prepared by the action of ICl (3 mols.) on a solution of aniline in HClAq (Michael & Norton, Am. 1, 255). Long white needles; sol. CS_2 and acetic ether; insol. water.

IDO-ANISIC ACID *p*. **Methyl derivative of IODO-OXY-BENZOIC ACID.**

IDO-BENZENE $\text{C}_6\text{H}_4\text{I}_2$. **Phenyl iodide.** Mol. w. 204. (188°). S.G. $\frac{4}{4}$ 1.8606; $\frac{15.2}{4}$ 1.8380 (Young, C. J. 55, 486); $\frac{2}{4}$ 1.8578; $\frac{1}{4}$ 1.8403; $\frac{2}{4}$ 1.8321. S.V. 130-55 (R. Schütz, B. 19, 564). $\mu = 1.6189$ (Seubert, B. 22, 2520).

Formation. — 1. By treating phenol with iodine and phosphorus. The yield is bad (Williamson & Sorgham, C. J. 13, 244). — 2. By the action of ICl on sodium benzate (Schützenberger, C. R. 52, 963). — 3. By heating benzene for some time with iodic acid (Peltzer, A. 136, 194). — 4. By the action of HI on diazobenzene salts (Griess, J. 1866, 447). — 5. By heating benzene (20 g.) with iodine (15 g.) and iodic acid (10 g.) at 220° (Kekulé, A. 137, 157). — 6. From benzene, iodine and FeCl_3 (Lothar Meyer, A. 281, 195). — 7. By the action of excess of iodine on phenyl hydrazine (E. v. Meyer, J. pr. 21, 36, 116).

Preparation. — By allowing chloride of iodine to drop slowly into a large excess of benzene

does not react with a small quantity of aluminium (J. pr. 90, 40).

Combinations. — 1. Colourless oil, insol. water. (J. pr. 93, 72) when dried by solid CO_2 . Easily heated to 100°, a part of the oil being reduced to benzene. Aqueous SO_2 , a little I being reduced to benzene. Not crystalline compound. HOH at 250°, nor by alcoholic ammonia as the compound (16).

Reaction with H_2SO_4 . at 100° forms a mixture of iodo-benzene sulphonic acid, di-iodo-benzene, and benzene sulphonic acid, in proportions varying with proportions of materials employed, strength of the acid, temperature, and duration of the experiment (Neumann, A. 241, 47). — 2. Silver nitrate does not act below 135°, but between 140° and 150° a reaction takes place forming tri-nitro-phenol, AgI , and metallic silver (Gräther, A. 245, 99). — 3. By heating with AlHCl_4 chloride there is formed benzene, H_2I , H_2I_2 , H_2I_3 , H_2I_4 , H_2I_5 , H_2I_6 , H_2I_7 , H_2I_8 , H_2I_9 , H_2I_{10} , H_2I_{11} , H_2I_{12} , H_2I_{13} , H_2I_{14} , H_2I_{15} , H_2I_{16} , H_2I_{17} , H_2I_{18} , H_2I_{19} , H_2I_{20} , H_2I_{21} , H_2I_{22} , H_2I_{23} , H_2I_{24} , H_2I_{25} , H_2I_{26} , H_2I_{27} , H_2I_{28} , H_2I_{29} , H_2I_{30} , H_2I_{31} , H_2I_{32} , H_2I_{33} , H_2I_{34} , H_2I_{35} , H_2I_{36} , H_2I_{37} , H_2I_{38} , H_2I_{39} , H_2I_{40} , H_2I_{41} , H_2I_{42} , H_2I_{43} , H_2I_{44} , H_2I_{45} , H_2I_{46} , H_2I_{47} , H_2I_{48} , H_2I_{49} , H_2I_{50} , H_2I_{51} , H_2I_{52} , H_2I_{53} , H_2I_{54} , H_2I_{55} , H_2I_{56} , H_2I_{57} , H_2I_{58} , H_2I_{59} , H_2I_{60} , H_2I_{61} , H_2I_{62} , H_2I_{63} , H_2I_{64} , H_2I_{65} , H_2I_{66} , H_2I_{67} , H_2I_{68} , H_2I_{69} , H_2I_{70} , H_2I_{71} , H_2I_{72} , H_2I_{73} , H_2I_{74} , H_2I_{75} , H_2I_{76} , H_2I_{77} , H_2I_{78} , H_2I_{79} , H_2I_{80} , H_2I_{81} , H_2I_{82} , H_2I_{83} , H_2I_{84} , H_2I_{85} , H_2I_{86} , H_2I_{87} , H_2I_{88} , H_2I_{89} , H_2I_{90} , H_2I_{91} , H_2I_{92} , H_2I_{93} , H_2I_{94} , H_2I_{95} , H_2I_{96} , H_2I_{97} , H_2I_{98} , H_2I_{99} , H_2I_{100} .

Di-iodo-benzene $\text{C}_6\text{H}_4\text{I}_2$. Formed by passing chlorine into liquid iodobenzene. Formed also by passing chlorine into a solution of iodobenzene (5 g.) in chloroform (15 g.) (Willgerodt, J. pr. 21, 33, 154). Begins to decompose at 20°, and at 120° it is all broken up into Cl_2 and $\text{C}_6\text{H}_5\text{I}$. It may be kept in glass bottles, but if placed over H_2SO_4 it gives off chlorine. It is decomposed by solution in alcohol, but it may be crystallised from chloroform as yellow needles. It dissolves in benzene, glacial acetic acid, light petroleum, CS_2 , and ether. As a reagent it displaces iodine by chlorine, turning KI , PbI_2 , SnI_4 , into KCl , PbCl_2 , SnCl_4 , &c., with separation of iodine. May therefore be used as a test for iodides. It also converts alcoholic iodides (e.g. MeI) into chlorides. It is hardly attacked by cold aqueous NH_3 or NaOH .

o-Di-iodo-benzene $\text{C}_6\text{H}_3\text{I}_2$. [1:2]. [27°]. [287°].

Preparation. — Iodo-aniline (10 g.) is dissolved in hot water (70 g.) containing H_2SO_4 (9 g.), KNO_3 (4.5 g.) dissolved in a little water is added, and then an excess of solution of KI in aqueous HI (S.G. 1.1). After standing a few hours the oil that has separated is washed with KOH and distilled with steam (Körner & Wender, G. 17, 486; cf. Körner, G. 4, 305). Long prisms or hexagonal tables. Volatile with steam. Sl. sol. water; spl. alcohol.

m-Di-iodo-benzene $\text{C}_6\text{H}_3\text{I}_2$. [1:3]. [40°] (K.); [37°] (R.). [285°]. From m-iodo-aniline by displacing NH_2 by I (Körner). Also from di-iodo-aniline by elimination of NH_2 (Rudolph). Trimetric tables (from ether-soluble).

p-Di-iodo-benzene $\text{C}_6\text{H}_3\text{I}_2$. [1:4]. [127°] (Kekulé); [129°] (Körner). A product of the action of iodine chloride on NaOBz (Schützenberger) and of iodine and iodic acid on benzene (Kekulé). Formed also from p-iodo-aniline by the diazo-reaction (Kekulé, Z. 1866, 688). Nacreous laminae. Readily sublimed.

Tri-iodo-benzene $\text{C}_6\text{H}_2\text{I}_3$. [2:2:1]. Mol. w. 456. [76°]. A product of the action of iodine and iodic acid on benzene (Kekulé). Small needles. May be sublimed.

IDO-BENZENE-AZOXY-COMPOUNDS *o*. **AZOXY-COMPOUNDS.**

IDO-BENZENE o-SULPHONIC ACID $\text{C}_6\text{H}_3\text{I}_2\text{SO}_3\text{H}$. [1:2]. From o-amido-benzene sulphonic acid by the diazo-reaction (Bahlmann, A.

186, 825).—KA' aq: crystals, sl. sol. w. BaA': needles, sl. sol. acid, v. sol. iodine and Chloride $C_6H_4SO_2Cl$ [51]. g. alcohols at (from ether). Give rise, in this

Amide $C_6H_4SO_2NH_2$. the iodine dis- mine, sl. sol. water.

Iodo-benzene sulphonio gives isopropyl 1:4). From iodo-benzene are formed by (Körner a. Paterno, G. 2, 448).

On the dry amido-benzene sulphonio acid. By the NH_2 by I through the diazo- re- gends. This

B. 10, 1135). Deliquescent needles than in minute needles.—KA': needles.—The attaches

minute plates, sl. sol. water.—Phenyl of carbon Chloride $C_6H_4SO_2Cl$. [87].

Amide $C_6H_4SO_2NH_2$. [189]. CH_3CH_2 powder, sl. sol. water, v. sol. alcohol.

o-iodo-benzoic acid $C_6H_4CO_2H$. [157].

Formation.—1. From o-amido-benzoic acid by the diazo- reaction (Griess, C. J. 2, KHSO).

2. By oxidising o-iodo-toluene with dis- (Kekulé, Z. 7, 1007).—3. From m-iodo-nitro-

benzene and alcoholic KCy at 200° (Richter, B. 4, 554).

Properties.—Long needles; may be readily sublimed. Sl. sol. hot water, v. e. sol. ether and alcohol. Gives salicylic acid when fused with

potash. Salts.—CaA', Baq.—BaA', Gaq. m-iodo-benzoic acid $C_6H_4CO_2H$. [187].

Formation.—1. From m-amido-benzoic acid by the diazo- reaction (Griess, A. 113, 334; 117, 1; Cunze a. Hüner, A. 135, 108; Grothe, J. pr. [2] 18, 824).—2. By heating benzoic acid

(1 pt.) with KIO_3 (2 pts.) and dilute H_2SO_4 (Peltzer, A. 136, 201).—3. By oxidising o-iodo-

toluene with chromic acid mixture (Körner, Z. [2] 5, 637).—4. By heating dry silver benzoate

with iodine at 150°–180° (Birnbbaum a. Reinherz, B. 19, 456).

Properties.—Needles, sl. sol. water, v. sol. alcohol. May be sublimed. Gives p-oxy-benzoic

acid on oxidation. Ammonia forms amido-ben- zoic acid.

Salts.—NaA' aq.—MgA', 4aq.—CaA', 2aq: scales.—CaA': nodules.—BaA', 4aq: needles, sol. alcohol.—MgA', 4aq.

Ethyl ether EtA'. Oil. Nitrile C_6H_4CN . [41]. From m-amido-

benzonitrile by the diazo- reaction. Needles. p-Iodo-benzoic acid $C_6H_4CO_2H$. [266].

(Beran, B. 18, 137; Klingel, B. 18, 2693). Formed by oxidation with chromic acid mixture

from p-iodo-toluene (Körner, Z. [2] 5, 327), from p-iodo-phenylacetic acid (Jackson a. Mabery,

Am. 2, 253), or from p-iodo-acetophenone (Klingel). Nacreous scales (from alcohol). Nearly

insol. boiling water. Converted by potash-fusion into p-oxy-benzoic acid.

Salts (Glassner, B. 8, 562).—NaA' aq: colourless needles, v. sol. water.—KA'—BaA', 1½aq: long trimetric plates.—CaA', 2q.—SrA', aq: nacreous laminae.—ZnA', 4aq: cubes.

Methyl ether MeA'. [114]. Long needles (Schmidt a. Schultz, A. 207, 833).

Ethyl ether EtA'. Oil. o-iodo-benzoic aldehyde C_6H_4CHO . [37].

Formed from o-nitro-cinnamic acid by successive conversion into amido-, diazo-, and iodo-cinnamic acid, and oxidation of the latter

with $KMnO_4$ (Stuart, C. J. 53, 140).

Does not act on ethyl-p-toluidine (B. 11, 107).—

8. By heating chloro- compounds with fuming HNO_3 (Lieben, Z. 1888, 712).—9. Nitrogen iodide,

acting on dilute alcoholic solutions of the potas- sium derivatives of phenols, forms iodo-phenols

and ammonia (Willgerodt, J. pr. [2] 87, 446).

Reactions.—1. The displacement of iodine by chlorine or bromine may be effected by heating

with the chloride or bromide of Hg, Cu, Ag, Sn, Pb, As, or Sb (v. Chloro- compounds and Bromo- compounds).—2. Chlorine and bromine displace

iodine directly.—3. Sodium frequently removes iodine with ease, e.g. $2C_6H_4I + Na_2 = C_6H_4 + 2NaI$.

In like manner (by what is known as Fittig's re- action): $C_6H_4I + C_6H_4I + Na_2 = C_6H_4.C_6H_4 + 2NaI$.

4. Water readily decomposes tertiary alkyl iodides, forming HI and a tertiary al-

p-Iodo-benzylamine [4:1] $C_6H_4CH_2NH_2$. Formed by heating p-iodo-benzonitrile a. Mabery, Am.

alcohol. [113]. Absorbs CO_2 from the air forming a carbonate [113].—B'HCl: slender white needles

[240°], sol. water and alcohol, sl. sol. ether.—B'H₂PtCl₄.

Di-p-iodo-di-benzylamine $(C_6H_4CH_2)_2NH$. [76°].

Formed, together with tri-p-iodo-tri- benzylamine, by boiling p-iodo-benzyl bromide

with alcoholic NH_3 (Jackson a. Mabery, Am. 2, 256; D. 11, 58; P. Am. A. 13, 209). White

needles; insol. water, v. sol. hot alcohol; ether, benzene, and CS₂.

Salts.—B'HCl: thick white plates, sol. CS₂ and HOAc, sl. sol. alcohol and benzene.—B'HBz: thick pearly prisms, insol. water, sl. sol. alcohol,

sol. ether, benzene, and CS₂.—B'H₂PtCl₄: minute yellow needles, almost insol. water and alcohol. —B'H₂CO₃. [113]. Crystalline.

Tri-p-iodo-tri-benzylamine $(C_6H_4CH_2)_3N$. [115°].

Formed as above (J. a. M.). White needles (from ether); v. sl. sol. hot alcohol, v. sol. ether, benzene, and CS₂.—B'H₂PtCl₄: yellow

needles, nearly insol. water and alcohol.

o-iodo-benzyl bromide $C_6H_4CH_2Br$. [53°]. Prepared by dropping bromine into o-

iodo-toluene heated to 190°–200° (Mabery a. Robinson, Am. 4, 102; P. Am. A. 17, 108).

Thick flattened prisms (from ligroin); v. sol. ether, hot alcohol, benzene, CS₂, and chloroform,

insol. water. Its vapour is very pungent. Gives o-iodo-benzoic acid on oxidation with dilute HNO_3 .

p-Iodo-benzyl bromide $C_6H_4CH_2Br$. [76°]. Prepared by heating p-iodo-toluene in bromine

vapour at 115°–150° (Jackson, Am. 1, 93). Straw- coloured needles, somewhat pungent. Insol.

water and cold alcohol, sol. hot alcohol, v. sol. ether. Hardly attacked by CrO_3 .

iodo-benzyl cyanide v. Nitrile of Iodo- phenyl-acetic acid.

o-iodo-benzylidene-malonic acid C_6H_4IO , i.e. $C_6H_4CH=O(CO_2H)_2$. [204°]. Formed

by heating equal weights of malonic acid and iodo-benzaldehyde for several hours at 100°

with half their weight of HOAc (Stuart, C. J. 53, 142). Decomposed on melting into CO_2 and o-iodo-cinnamic acid.

o-iodo-benzyl-malonic ether $C_6H_4CH_2O(CO_2Et)_2$. From sodium benzyl- malonic ether and iodine (Bischoff a. Hausdörfer,

A. 289, 110). Oil. Decomposes on hydrolysis

SL. (C.) (cf. Weber, P. 128, 459).—7. Carbon dioxide passed over HI, forms a little COCl_2 (C.). 8. IOL. shaken with silver oxide forms AgCl and HIO_3 . Heated with excess of Ag_2O , Ag periodate (Philipp, B. 8, 4).—9. Hydrogen has no action at the ordinary temperature; when the IOL. is slightly warmed HCl + IOL. are produced; at a higher temperature, H_2 (Hofmann, Ber., 64). Prisms or needles; heavier than water.

Has no action on litmus. Sl. sol. cold water; v. sol. other solvents. Bromine converts it into tri-bromo-aniline. — B^*HCl : thin laminae or needles (from hot water); sl. sol. cold water, almost insol. HClAq ; sol. alcohol, insol. ether. — $\text{B}^*\text{H}_2\text{PtCl}_6$: orange pp. — $\text{B}^*\text{H}_2\text{C}_2\text{O}_4$: long needles, in water and alcohol, insol. ether. — $\text{B}^*\text{H}_2\text{SO}_4$:

IODO-BUTANE v. BUTYL IODIDES.

HI. iodo-butane $\text{C}_4\text{H}_9\text{I}$, i.e.

From the action of HI on $\text{C}_4\text{H}_9\text{Br}$. S.G. 2.291. (Wurtz, B., [2] 41, 362).

p -IODO-ISOBUTYL-BENZENE $\text{C}_{10}\text{H}_{11}\text{IO}$ (258° cor.). Formed by the action of HI on the diazo compound from p -amido-phenyl-butane (Pahl, B. 17, 1232). Colourless oil. By HNO_3 it is oxidised to p -iodo-benzoic acid.

IODO-BUTYLENE $\text{C}_4\text{H}_6\text{I}_2$. Crotyl iodide. (182°). From tri- oxy -butane (butenyl-glycerin), iodine and phosphorus (Lieben a. Zeisel, M. 1, 836). Pungent liquid. Combines with mercury forming an unstable crystalline compound.

IODO-ISOBUTYL-TOLUENE $\text{C}_9\text{H}_9\text{I}$ (1.3.6). [c. 85°]. (264°). Formed by diazotising amido-tolyl-isobutane and treating the product with HI (Effront, B. 17, 2325). Long white needles. V. sol. alcohol and ether. On oxidation with HNO_3 at 200° it gives nitro-tolyl-isobutyric acid.

α -IODO- γ -BUTYRIC ACID $\text{C}_4\text{H}_7\text{IO}_2$, i.e. $\text{CH}_3\text{CH}_2\text{CH}(\text{I})\text{CO}_2\text{H}$. [110°] (Fittig, B. 9, 1194). From α -crotonic acid and fuming HI at 100° (Hemilian, A. 174, 324; v. *infra*). Monoclinic crystals (Haushofer, Z. K. 6, 135).

Ethyl ether EtA'. (191°). Formed by boiling α -bromo-butyric ether with alcoholic KI (Hell, B. 6, 29).

β -Iodo-butyric acid $\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$. Formed, in small quantity, in the preparation of the preceding. Liquid.

According to Michael and Freer (J. pr. [2] 40, 95), HI unites with solid crotonic acid forming, contrary to the statement of Hemilian, only β -iodo-butyric acid, of low melting-point. The same acid is formed from liquid crotonic acid and HI . Boiling water converts it into β -oxy-butyric acid. Hot NaOH gives solid crotonic acid.

γ -Iodo-butyric acid $\text{CH}_3\text{CH}(\text{I})\text{CH}_2\text{CO}_2\text{H}$. [41°]. From the lactone of γ -oxy-butyric acid and HI (Henry, C. R. 102, 868; A. Saytzeff, B. 14, 2826). Colourless plates, which become yellow in sunlight. Sl. sol. warm water (difference from β -isomeride), v. sol. methyl alcohol, ether, and CS_2 .

Methyl ether MeA'. (199°). S.G. 1.666. Oil, with pleasant odour.

Iodo-isobutyric acid $(\text{CH}_3)_2\text{CHCO}_2\text{H}$ (?). [86°]. From methacrylic acid and fuming HI at 0° (Fittig a. Paul, A. 188, 58; 200, 67). Tables (from CS_2) or large prisms (from conc. HClAq). Sl. sol. water.

does not react with isobutyric acid $\text{C}_4\text{H}_9\text{IO}_2$. [127°].

Combinations.—1. Extracting the product with (J. pr. 88, 72) when dry. 2. Tafel, B. 22, 108). Long heated to 100°, a pale yellow oil and ether. 3. SO_2 , a little I being added. 4. HCl or $(\text{CH}_3)_3\text{CCOOH}$. S.G. crystalline compound.

By treating isobutyric aldehyde with HI and I_2 in 40 c.c. of alcohol, benzene, and CCl_4 , obtain pure, 100%, of the crude tions varying with more than 1 g. sufficiently pure employed, strength of silver removes the excess and duration of reduced silver removes the excess 24, 47).—2. S.G. [6] 16, 160).

Properties.—Heavy liquid, colourless when pure. Vapour is, like its homologues, ex-pure, irritating. It is completely decomposed by HI , and cannot be distilled even in HI . It forms a crystalline compound with ONH_2 which is rapidly resinified by solutions of alkalis, mineral acids. Combines with aniline, with elimination of water, giving a di-amine. $\text{Ag}(\text{C}_2\text{H}_3\text{O}_2)$ at 100° yields isobutyl acetate (114°). AgCN and AgSCN yield the corresponding cyano- and sulphocyan- derivatives.

IODO-CAMPFOR v. CAMPFOR.

IODO-CAPROIC ACID v. IODO-HEPTOIC ACID.

IODO-CAPRYL-BENZENE v. IODO-OCTYL-BENZENE.

IODO-CARBOSTYRIL v. IODO-OXY-QUINOLINE.

IODO-CHELIDONIC ACID v. CHELIDONIC ACID.

IODO-CHEYSIN v. CHEYSIN.

α -IODO-CINNAMIC ACID $\text{C}_9\text{H}_7\text{IO}_2$, i.e.

$\text{C}_6\text{H}_5\text{CH}(\text{I})\text{CH}=\text{CHCO}_2\text{H}$. [214°] (G. a. H.); [307°] (S.). Formed by boiling α -diao-cinnamic acid with aqueous HI (Gabriel a. Herzberg, B. 16, 2037). Formed also by heating α -iodo-benzylidene-malonio acid to its melting-point (Stuart, C. J. 53, 142). Crystals (from dilute alcohol).

γ -Iodo-cinnamic acid $\text{C}_9\text{H}_7\text{IO}_2$, i.e. $\text{C}_6\text{H}_5\text{CH}(\text{I})\text{CH}_2\text{CO}_2\text{H}$. [182°]. Formed by boiling γ -diao-cinnamic acid with HI (G. a. H.). Sol. benzene, petroleum-ether, and hot alcohol, sl. sol. water.

β -Iodo-cinnamic acid $\text{C}_9\text{H}_7\text{IO}_2$, i.e. $\text{C}_6\text{H}_5\text{CH}(\text{I})\text{CH}=\text{CHCO}_2\text{H}$. [c. 255°]. Formed by boiling β -diao-cinnamic acid with HI (Gabriel a. Herzberg, B. 16, 2040). Crystalline mass.

IODO-CODEINE v. CODEINE.

IODO-COMPOUNDS. Organic compounds containing iodine attached to carbon.

Formation.—1. Unlike chlorine and bromine, iodine is not capable of directly displacing hydrogen, inasmuch as the HI produced would cause a reverse reaction. But if iodic acid, mercuric oxide, or some other substance capable of removing HI be present, the substitution may take place (Kekulé, A. 181, 281). In the case of aniline, the free HI combines with excess of aniline and thus iodo-aniline may be formed. Mercuric oxide will not induce the iodation of fatty compounds, but is especially useful in the case of phenols and oxy-acids (Veselsky, A. 174, 99). The operation is performed in boiling alcoholic solution, and an intermediate body appears to be mercuriiodate (Lippmann, B. 7, 1778). Aromatic hydrocarbons may be iodated by heating with iodine and dry FeCl_3 (L. Meyer, A. 281, 195).—2. By the action of HI on hydroxylic compounds.

The alkyl iodide is prepared in the latter, of iodine and corresponding alcohols at alcohols give rise, in this alkyl iodides, the iodine dis-

attached to a penultimate carbon: thus glycerin gives isopropyl iodide. Iodides of acid radicals are formed by the action of iodine or phosphorus on the dry salts (Cahours, *Z.* 104, 111).—8. By the action of HI with unsaturated compounds. This combination takes place more readily than in the case of HCl and HBr. The iodine attaches itself to that one of the involved atoms of carbon that is combined with the smaller amount of hydrogen, e.g.: $\text{CH}_3\text{CH}=\text{CH}_2 + \text{HI} = \text{CH}_3\text{CH}_2\text{CH}_2\text{I}$. From aromatic amino-compounds by the diazo-reaction. This may be performed by heating the iazo-compounds with HIAq, or with aqueous KI, e.g.: $\text{C}_6\text{H}_5\text{N}_2\text{SO}_3\text{H} + \text{KI} = \text{C}_6\text{H}_5\text{I} + \text{N}_2 + \text{KHSO}_3$. Also by Sandmeyer's reaction, which consists in boiling the diazo-compound with cuprous iodide, v. Diazo-compounds.—5. By gradually adding HNO_3 to a hot solution of the amine in HIAq (Losanitsch, *B.* 18, 39).—6. By displacing Cl or Br by I by treatment with a metallic iodide. The elements K, Mg, Ca, Sr, Ba, Al, Mn, and Co prefer chlorine and bromine to iodine, and hence the iodides of these metals when heated with chloro- or bromo-compounds produce iodo-compounds (Köhnelein, *A.* 225, 194). Thus propyl chloride is converted into propyl iodide by CaI_2 , SrI_2 , MnI_2 , and CoI_2 , while it is but slightly affected by NiI_2 and FeI_2 , is not affected by SnI_2 , and is wholly decomposed by PI_3 . The conversion of benzyl chloride into benzyl iodide is partially effected by BaI_2 at 15° , by ZnI_2 at 10° , by CdI_2 at 100° , and by PbI_2 at 160° . On the other hand, isobutyl chloride is not converted into iodide at 70° by BaI_2 , by ZnI_2 , or by CdI_2 ; while CdI_2 at 135° decomposes it. The substitution of Cl in chloro-acetic acid by I is partly effected by CdI_2 or TI at 100° , and may be effected by BaI_2 or ZnI_2 at 100° (Brix, *A.* 220, 166). Potassium iodide is a very convenient reagent for the purpose (Perkin a. Duppa, *A.* 112, 125), but cannot be always depended upon; for though it displaces Cl by I in the case of epichlorhydrin, chloro-lactic acid, dichlorhydrin, and mono- and di-chloro-acetone, it does not act on di-chlorinated ether, and it decomposes chloroform into chloroform and CO . Calcium iodide $\text{CaI}_2 \cdot 8\text{H}_2\text{O}$ is also an excellent reagent for converting chloro- and bromo-compounds into the corresponding iodo-derivatives (Sandler, *A.* 231, 257). Thus it converts $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$ into ethylene iodide, and CH_3CHClBr into CH_3CHI ; but it fails with $\text{CH}_3\text{CH}_2\text{CHCl}_2$, with $\text{CHCl}_2\text{CHCl}_2$, with $\text{CCl}_3\text{CHCl}_2$, with $\text{C}_6\text{H}_5\text{Cl}$, with chloro-benzene, and with anisole. Dry CaI_2 requires a higher temperature (120°) before it reacts, and this decomposes many of the iodo-compounds that should be formed.—7. Iodine chloride also acts as an iodating substance, especially upon aromatic amines. Thus it converts aniline (dissolved in HOAc) into di-iodo-aniline (when 2 mols. ICl are used) and tri-iodo-aniline (when 3 mols. ICl are used). It converts acetanilide into acetyl-p-iodo-aniline, m-nitro-aniline into di-iodo-m-nitro-aniline, p-nitro-aniline chiefly into iodo-p-nitro-aniline, and p-toluidine into di-iodo-p-toluidine: but it

does not act on acetyl-p-toluidine (*B.* 11, 107).—8. By heating anhydro-compounds with fuming HIAq (Lieben, *Z.* 1868, 746).—9. Nitrogen iodide, acting on dilute alcoholic solutions of the potassium derivatives of phenols, forms iodo-phenols and ammonia (Willgerodt, *J. pr.* [2] 87, 446).

Reactions.—1. The displacement of iodine by chlorine or bromine may be effected by heating with the chloride or bromide of Hg, Cu, Ag, Sn, Pb, As, or Sb (v. Chloro-compounds and Bromo-compounds).—2. Chlorine and bromine displace iodine directly.—3. Sodium frequently removes iodine with ease, e.g. $2\text{C}_6\text{H}_5\text{I} + \text{Na} = \text{C}_6\text{H}_5\text{Na} + 2\text{NaI}$. In like manner (by what is known as Fittig's reaction): $\text{C}_6\text{H}_5\text{I} + \text{C}_6\text{H}_5\text{I} + \text{Na} = \text{C}_6\text{H}_5\text{C}_6\text{H}_5 + 2\text{NaI}$. 4. Water readily decomposes tertiary alkyl iodides, forming HI and a tertiary alcohol. Methyl and ethyl alcohol at 100° act in like manner, forming a tertiary alcohol and MeI or EtI.—5. Silver obtained by reduction sometimes removes iodine: e.g. $2\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H} + \text{Ag} = 2\text{AgI} + \text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$.

Some aromatic iodo-compounds can take up chlorine, e.g. PhI gives PhICl_2 (Willgerodt, *J. pr.* [2] 83, 154), $\text{C}_6\text{H}_5\text{BrI}$ gives $\text{C}_6\text{H}_5\text{BrICl}_2$, while $\text{C}_6\text{H}_5\text{Br}_2\text{I}$ gives $\text{C}_6\text{H}_5\text{Br}_2\text{ICl}_2$, and $\text{C}_6\text{H}_5(\text{NO}_2)_2\text{I}$ gives $\text{C}_6\text{H}_5(\text{NO}_2)_2\text{ICl}_2$. $\text{C}_6\text{H}_5(\text{NO}_2)_3\text{I}$ has no action.

iodo-m-cresol $\text{C}_6\text{H}_4\text{MeI}(\text{OH})$ [1:3:8]. Oil Formed by adding iodine to a solution of m-cresol in ammonia and alcohol (Willgerodt a. Kornblum, *J. pr.* [2] 89, 289).

Iodo-p-cresol $\text{C}_6\text{H}_4\text{MeI}(\text{OH})$ [1:3:4]. Formed by the action of dry iodine on sodium-p-cresol suspended in CS_2 (Schall a. Dralle, *B.* 17, 2538). Liquid. Volatile with steam.

Methyl ether $\text{C}_6\text{H}_4\text{MeI}(\text{OMe})$ (238°); oil. **Di-iodo-o-cresol** $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})$ [1:3:4:2]. [70°]. Formed by the action of iodide of nitrogen upon the sodium compound of o-cresol (Willgerodt, *J. pr.* [2] 87, 448, 39, 289).

Acetyl derivative $\text{C}_6\text{H}_4\text{MeI}(\text{OAc})$ [56°]. Tables.

Picrate. [204°]. Yellow crystalline aggregates.

Di-iodo-m-cresol $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})$ [76°]. Formed together with iodo-m-cresol (W. a. K.). Long needles, sol. usual menstrua.

Di-iodo-p-cresol $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})$ [1:3:5:4]. [61°]. Formed together with the preceding (Schall a. Dralle, *B.* 17, 2534). White tables. Easily soluble in alcohol, sparingly in water and ligroin. Volatile with steam.

Acetyl derivatives $\text{C}_6\text{H}_3\text{Me}_2(\text{OAc})$ [62°], white tables.

Benzoyl derivative $\text{C}_6\text{H}_3\text{Me}_2(\text{OBz})$ [180°], glistening white prisms.

Ethylether $\text{C}_6\text{H}_3\text{Me}_2(\text{OEt})$ [77°]. White solid, sol. organic solvents (Willgerodt a. Kornblum, *J. pr.* [2] 89, 289).

iodo-cresol sulphonic acid $\text{C}_6\text{H}_4\text{MeI}(\text{OH})\text{SO}_3\text{H}$ [3:1:2:5]. [155°]. Formed together with an isomeride, by the action of iodine on the potassium salt of o-cresol-sulphonic acid (Wehrmann, *J. pr.* [2] 87, 338). Colourless plates (containing 8aq). Converted by nitric acid into dinitro-cresol [86°]. Chromic acid forms iodo-toluidine [115°].

Salts.—A'K: fine needles.—A'Ba 4aq.

Di-iodo-m-cresol sulphonic acid $\text{C}_6\text{H}_3\text{Me}_2(\text{OH})\text{SO}_3\text{H}$ [3:5:2:1:4]. [70°]. From potassium m-cresol sulphonate by treatment with

iodo-CRESOL SULPHONIC ACID.

Iodine (Kehrmann, *J. pr.* [2] 89, 892). Small needles. Oxidised by CrO_3 to di-iodo-toluquinone.

iodo-ψ-CUMENE $\text{C}_9\text{H}_7\text{I}$, [1:2:4:5]. *Iodo-tri-methyl-benzene*. [37°]. (258°). Formed by decomposing ψ-cumene diazopiperide with HIAg (S.G. 1:78) (Wallach & Heusler, *A.* 243, 238). Formed also from ψ-cumidine by diazotising and heating the product, dissolved in H_2SO_4 with KI (Kürzel, *B.* 22, 1586). Scales. Treatment with H_2SO_4 forms two isomeric di-iodo-ψ-cumene sulphonic acids: ψ-cumene sulphonic acid and iodo-ψ-cumene sulphonic acid. One of the di-iodo-ψ-cumenes melts at 74°, the other is an oil.

iodo-ψ-CUMENE SULPHONIC ACID $\text{C}_9\text{H}_6\text{I}_2\text{SO}_3\text{H}$. Formed as above. Scales, m. sol. water.

Salts.— NaA : aq. plates.— BA' : aq. needles.

iodo-CYANETHINE v. **CYANETHINE**.

iodo-ETHANE v. **ETHYL IODIDE**.

Di-iodo-ethane v. **ETHYLENE IODIDE** and **ETHYLIDENE IODIDE**.

Tri-iodo-ethane $\text{C}_2\text{H}_3\text{I}_3$, i.e. CH_3I_3 , [95°]. Formed by the action of aluminium iodide upon CH_3COI (De Boissieu, *Bl.* [2] 49, 16). Yellow octahedra. V. s. sol. CS_2 , benzene, and ether; v. sol. petroleum-ether; m. sol. alcohol. Smells faintly of iodoform.

iodo-ETHYL ALCOHOL v. **GLYCOL IODHYDRIN**.

β-iodo-ETHYL-AMINE $\text{C}_2\text{H}_5\text{CHI}_2\text{NH}_2$.

Hydriodide BHI . [194°]. From vinylamine and conc. HIAg (Gabriel, *B.* 21, 1049). Trimetric crystals (from hot alcohol). V. sol. water. When treated with KOH it gives a liquid, soluble in water, with a disagreeable odour.

Picrate $\text{B}'\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ [c. 105°] (hydrated); [181°] (anhydrous). Short compact yellow prisms.

Di-iodo-ethyl-amine EtNI , v. **Ethyl-di-iodo-amine**, vol. ii. p. 474.

α-DI-iodo-ETHYL-BENZENE $\text{C}_8\text{H}_7\text{I}_2$, i.e. $\text{C}_6\text{H}_5\text{CHICH}_2\text{I}$. *Styrene di-iodide*. From styrene and a concentrated solution of iodine in KIAg (Berthelot, *Bl.* 6, 295, 7, 277). Crystals; v. sol. ether. Rapidly decomposes into iodine and meta-styrene.

iodo-ETHYLENE $\text{C}_2\text{H}_2\text{I}_2$, i.e. CH_2CHI . *Vinyl iodide*. (56°). S.G. 2:08. Formed by distilling ethylene iodide with conc. alcoholic potash, the receiver being kept very cool, and the distillate finally mixed with water (Regnault, *A.* 15, 69; E. Kopp, *C. R.* 18, 871). Also from ethylidene iodide (Gustavson, *B.* 7, 731). Formed also by the union of HI with acetylene (Berthelot, *A.* 182, 122; Semenov, *Z.* 1865, 725). Oil; v. sol. alcohol and ether, with alliaceous odour.

Di-iodo-ethylene $\text{C}_2\text{H}_2\text{I}_2$, i.e. CHI:CHI . *Acetylene di-iodide*. [78°]. (129° cor.). S.G. 2:802. Formed by passing acetylene over iodine moistened with alcohol (Sabanejeff, *A.* 178, 109; 216, 275; Plimpton, *O. J.* 41, 892). Elastic needles (from alcohol). It appears to be accompanied by a small quantity of a liquid isomeric. S.G. 2:942. With alcoholic AgNO_3 it forms long needles of a compound $\text{C}_2\text{H}_2\text{I}_4\text{AgNO}_3$, which is decomposed by HCl , giving off acetylene.

Tetra-iodo-ethylene C_2I_4 , *Di-carbon-tetra-iodide*. [c. 165°]. Prisms. Formed by the action of a solution of iodine in aqueous KI upon the cuprous compound of potassium propargylate. Formed also by the action of the

iodine solution upon acetylene copper (Homolka & Stolz, *B.* 18, 2283).

iodo-ETHYLIDENE DI-ETHYL DI-SULPHONE $\text{CH}_2\text{I}(\text{SO}_2\text{Et})_2$. [109°]. From ethylidene di-ethyl di-sulphone by boiling with iodine (Fromm, *A.* 253, 146). Needles.

iodo-DI-ETHYL OXIDE $\text{C}_2\text{H}_5\text{IO}$, i.e. $\text{CH}_3\text{ICH}_2\text{OEt}$. (155°). S.G. 2:1692. V.D. 6:91 (obs. and calc.). Formed by heating ethylene iodide with alcohol at 75° (Baumstark, *B.* 7, 1172). Formed also from the mono-ethyl derivative of glycol by treatment with iodide of phosphorus (Demole, *B.* 9, 746). Pungent oil, not decomposed by water. Alcoholic potash attacks it energetically, yielding $\text{CH}_3\text{CH}_2\text{OEt}$ (35°), and $\text{CH}_3(\text{OEt})\text{CH}_2(\text{OEt})$ (122°). Boiling with reduced silver does not affect it.

iodo-(8)-ETHYL-THIOPHENE

$\text{C}_8\text{H}_7(\text{C}_2\text{H}_5)\text{IS}$. Oil. Formed by the action of iodine upon (8)-ethyl-thiophene in presence of HgO (Bonz, *B.* 18, 551).

iodo-FLUORO-BENZENE v. **FLUORO-iodo-BENZENE**.

iodoFORM CHI_3 . *Tri-iodo-methane*. Mol. w. 394. [119°]. S.G. 2.

Depression of freezing-point of benzene by iodoform: Raoult, *A. Ch.* [6] 2, 88; Paterno, *B.* 22, 465.

Formation.—1. By heating alcohol with iodine and caustic or carbonated alkali (Serullas, *A. Ch.* [2] 25, 314). Iodoform is formed in like manner by the action of iodine and potash on aldehyde, acetone, lactic acid, and many other substances (cf. vol. i. p. 96).—2. From chloroform and HI (Baeyer, *B.* 5, 1094).—3. By heating chloroform with CaI_2 at 75° (Spindler, *A.* 231, 263).—4. Together with carbamic ether, by the action of iodine on sodium carbamic ether (Mulder, *R. T. C.* 7, 333).

Preparation.—1. Alcohol containing about 20 p.c. aldehyde is mixed with ten times its weight of aqueous NaOH, iodine is added, and the mixture stirred from time to time. The iodoform quickly separates in the cold (Günther, *Ar. Ph.* [3] 25, 378).—2. To prepare iodoform R. Rothér (*Ph.* [3] 4, 593) heats 32 pts. iodine, 32 potassium carbonate, 16 alcohol of 95 per cent. and 80 water, till the mixture becomes colourless; then decants the clear liquid, collects the separated crystals of iodoform, and mixes the filtered liquid with 16 to 24 pts. hydrochloric acid and 2 to 3 pts. potassium dichromate. The liquid is then neutralised with potassium carbonate, and 32 pts. more of that salt are added, together with 6 pts. iodine and 18 alcohol. The reaction having been completed at the heat of the water-bath, the product is treated as above, whereby a fresh quantity of iodoform is obtained.—3. By the action of excess of sodium hypochlorite on an aqueous solution of acetone (6 pts.), potassium iodide (50 pts.), and NaOH (2 pts.) (Suares, Baynaud, *Bl.* [3] 1, 8).

Properties.—Hexagonal yellow tables; $\alpha = 1:9015$ (Rampelsberg & Kokscharoff, *O. C.* 1857, 524; cf. Dogiel, *N. Peterb. Acad. Bull.* 20, 887). Above its melting-point it partly decomposes, giving off iodine and HI. Has a peculiar persistent odour. Volatile with steam. Insol. water, acids, and alkalis; v. sol. alcohol, ether, and fixed and volatile oils. An alcoholic solution of iodoform is decomposed under the influence of

ugns. The decomposition is accelerated by dry oxalic acid; iodine and methylene iodide are produced (Mulder, *R. T. C.* 7, 816; cf. Humbert, *J. Ph.* [8] 29, 352). Does not in the least hinder the putrefaction of pancreas at 85° (Boillat, *J. pr.* 188, 868).

Detection.—An alcoholic solution of iodoform warmed with aqueous KOH and a little phenol forms a red substance, which dissolves in dilute alcohol, giving it a crimson colour (Lustgarten, *M.* 8, 717).

Reactions.—1. Heated in a sealed tube at 180°, either alone or with iodine, it yields methylene iodide and brown products (Hofmann, *U. J.* 13, 65).—2. Bromine gives bromoform (Löscher, *B.* 21, 410); but an excess of Br at high temperatures forms CBr₄.—3. Distilled with HgCl₂ it yields CHCl₃ (Schlagdenhauffen, *J. Ph.* [8] 29, 247).—4. Mercuric oxide forms PO, formic acid, HgI₂, and water.—5. Boiling aqueous KOH forms a little potassium formate.—6. Boiling alcoholic potash forms methylene iodide (Bruning, *A.* 104, 187; Butlerow, *C. R.* 47, 595).—7. NaOEt forms methylene iodide, NaI, aldehyde, acrylic acid, and CH₃.CH(OEt).CO₂H (Butlerow, *A.* 107, 110; 114, 204; 118, 325).—8. K₂SO₄ forms CH₃(SO₃K) (Strecker, *A.* 148, 90).—9. By the copper-zinc couple iodoform may be reduced to methane (Gladstone & Tribe, *C. J.* 28, 508).—10. Unites with PBr₃ forming C₃H₇PBr₃ (Hofmann, *Pr.* 10, 189).—11. PCl₅ forms chloroform. 12. When made into a paste with moist finely-divided silver, acetylene is at once given off. A mixture of ppd. silver and copper is even more effective (Cazeneuve, *C. R.* 97, 1371).—13. Silver nitrate acts readily at ordinary temperatures, forming AgI, nitric acid, and CO, so that by nitrating the liberated acid an estimation of the quantity of iodoform present may be formed (Grashoff, *R. G. C.* 7, 342).—14. Iodoform exposed to direct sunlight is completely oxidised by air, forming CO₂, iodine, and water (Dacomo, *G.* 16, 247).—15. Mercuric acetate is reduced by iodoform to mercurous acetate, CO₂ being evolved. It does not reduce mercuric nitrate (although chloral forms, in this case, mercurous chloride) (Cotton, *J. Ph.* [5] 16, 481).—16. Isobutyl alcohol (200 g.) mixed with sodium (20 g.) and iodoform (100 g.) gives a violent reaction, the products being formic acid, isobutyric acid, pentenoic acid, CMe₂.CH.CO₂H [70°], isobutyl-oxo-isobutyric acid C₂H₅O.CMe₂.CO₂H, a lactone of an oxo-octioic acid, isobutylene, methyl isobutyl oxide, methylene isobutyl oxide, a compound C₇H₁₂O₂, and other bodies (Gorboff & Kessler, *J. R.* 1887, 428).

IODO-FUMARIC ACID C₄H₄(CO₂H)₂. *Iodo-maleic acid*. [184°]. Formed by dissolving acetylene-di-carboxylic acid in strong aqueous HI (Baudrowski, *B.* 15, 2697). Fine glistening crystals. Very soluble in water, alcohol, and ether.

Salts.—A'HK; small sparingly soluble crystals.—A'Ag; crystalline pp.—A'Pb 2aq; crystalline pp.

IODO-HEXENOIC ACID C₁₁H₁₀IO₂. *i.e.* $\text{CH}_2\text{CH}(\text{CH}_2)_4\text{CH}(\text{CO}_2\text{H})_2$. [24°]. From hexenoic acid and HI (Ph. Brunner, *B.* 19, 2224). Crystalline.

IODO-HEPTOIC ALDEHYDE C₈H₁₁IO. *i.e.* $\text{CH}_2\text{CH}(\text{CH}_2)_5\text{CHO}$. [2-31°]. Formed by treating heptioic

(osnanthio) aldehyde (75 g.) diluted with alcohol (100 c.c.) with iodine (50 g.) and iodic acid (20 g.). The crude product is purified by treatment with reduced silver. The yield is very bad (Chautard, *A. Ch.* [6] 16, 170). Very unstable liquid with irritating odour. Decomposed by heat. Easily decomposed by KOH, NaOH, ammonia, and mineral acids.

Reactions.—1. Nitric acid gives heptioic aldehyde and heptioic acid.—2. Silver acetate forms octyl acetate (208°).—3. By heating iodo-heptioic aldehyde (120 g.) dissolved in alcohol with silver cyanide (87 g.) there is formed C₈H₁₇CHO (177°) S.G. 12-913. This is a colourless liquid which reduces Fehling's solution and ammoniacal AgNO₃, but does not form crystalline compounds with aniline or phenyl-hydrazine.—4. Silver sulphocyanide forms the corresponding sulphocyno-heptioic aldehyde.—5. Heating with aniline forms C₈H₁₁(NHCO₂H)₂.

IODO-HEPTYLENE C₈H₁₁I. *i.e.* $\text{Pr.CH}_2\text{CH}(\text{CHMe})\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$. (140°-150°). From heptinene (*q. v.*) and HI (Morris, *C. J.* 41, 179).

IODO-HEXANE v. HEXYL IODIDE.

Di-iodo-hexane C₆H₁₂I₂. *i.e.* $\text{CH}_3\text{CHICH}_2\text{CH}_2\text{CHICH}_3$. *Hexylene iodide*. S.G. 2-024. Formed by heating di-allyl in a sealed tube for 5 hours with excess of mono. HIAq at 100° (Wurtz, *A. Ch.* [4] 3, 129); or better, by passing gaseous HI into strongly cooled diallyl (Sorokin, *J. pr.* [2] 28, 18). Oil; gives off iodine when heated. With sodium it gives hexylene and hexenyl iodide. Alcoholic potash forms diallyl. Silver acetate forms hexylene acetate C₆H₁₁(OAc), whence baryta forms di-oxo-hexane.

Tetra-iodo-hexane C₆H₄I₄. [above 100°]. From diallyl and iodine (Berthelot & De Luca, *A.* 100, 363).

TETRA-IODO-HEXINENE v. Tetra-iodide of DIPROPARGYL.

IODO-HEXOIC ACID C₆H₉IO₂. Formed by mixing hydrosorbic acid with conc. HIAq at 0° (Fittig, *A.* 200, 44). Oil, turning yellow on exposure to light. May be reduced by sodium-amalgam to *n*-hexic acid.

IODO-HEXYLENE C₈H₁₁I. *i.e.* $\text{CH}_2\text{CH}(\text{CH}_2)_4\text{CHICH}_3$. *Hexenyl iodide*. *Diallyl hydroiodide*. (165°). S.G. 2-1497. Formed, together with di-iodo-hexane, by the action of HI on diallyl (Wurtz, *A. Ch.* [4] 3, 155). Formed also by the action of alcoholic potash or of an alloy of tin and sodium on di-iodo-hexane $\text{CH}_3\text{CHICH}_2\text{CH}_2\text{CHICH}_3$. When treated for 24 hours with moist Ag₂O it forms diallyl, hexylene, and two liquids C₈H₁₁O (*c.* 185°) and C₈H₁₀O (180°).

Iodo-hexylene C₈H₁₁I. (181°). S.G. 12-192. Formed from the hexenyl alcohol obtained by distilling glycerin with lime (Destrem, *A. Ch.* [6] 27, 58).

Iodo-hexylene C₈H₁₁I. (142°-145°). From pinosone hydrate and HI at 160° (Bouchardat, *Z.* 1871, 699). Reduced by tin and HCl to hexylene. Bromine gives crystalline C₈H₁₁Br.

IODO-HIPPURIC ACID C₈H₇INO. *i.e.* $\text{NH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$. Formed by treating a boiling alcoholic solution of hippuric acid with iodine (Maier, *Z.* 1865, 415). White needles. Decomposes at 90°. All its salts are soluble in water excepting the silver salt.

iodo-hippuric acid.

Iodo-hippuric acid $C_9H_7I.CO.NH.CH_2.CO_2H$. Formed by the action of aqueous HI on the sulphate of diazo-hippuric acid (Griess, *Z.* [2] 4, 725; *B.* 1, 190). Laminæ, v. sol. cold alcohol and ether, m. sol. hot water, nearly insol. cold water. The iodine is not easily removed.

iodo-HYDROCINNAMIC ACID v. **Iodo-PHENYL-PROPIONIC ACID**.

DI-iodo-HYDROQUINONE $C_6H_2I_2(OH)_2$ [5:3:4:1]. [145°]. Formed by boiling di-iodoquinone [180°] with a dilute solution of $SnCl_2$ (Seifert, *J. pr.* [2] 28, 488; Kehrman, *J. pr.* [2] 87, 387). Long colourless needles (from hot water). Volatile with steam.

Di-iodo-hydroquinone $C_6H_2I_2(OH)_2$. [142°]. From di-iodoquinone [159°] and aqueous SO_2 (Metzeler, *B.* 21, 2555). White needles, v. sol. hot water, alcohol, ether, and $HOAc$; m. sol. benzene. Reoxidised by $FeCl_3$ to di-iodoquinone.

Di-acetyl derivative $C_6H_2I_2(OAc)_2$. [148°]. Needles or plates (from alcohol); insol. water, v. sol. alcohol and ether, sl. sol. cold $HOAc$.

iodo-HYDROTHYMOQUINONE $C_8H_6I_2Pr(OH)_2$ [74°]. Obtained by reducing iodo-thymoquinone with $SnCl_2$ (Kehrman, *J. pr.* [2] 89, 392). Colourless plates, v. sol. organic solvents.

iodo-HYDRO-TOLUQUINONE $C_8H_5MeI_2(OH)_2$ [6:2:4:1]. [111°]. From the corresponding quinone, by reduction with $SnCl_2$ (Kehrman, *J. pr.* [2] 89, 392). Soft silky aggregates of needles, sol. organic solvents.

iodol v. **TETRA-iodo-PYRROLE**.

iodo-LACTIC ACID v. **iodo-OXY-PROPIONIC ACID**.

iodo-MALEIC ACID v. **iodo-FUMARIC ACID**.

iodo-MELILOTTIC ACID. *Methyl derivative*. $C_{10}H_7IO$, i.e. $C_6H_4(OMe).C_2H_4.CO_2H$. From the methyl derivatives of (a) and of (b) coumaric acid and fuming aqueous HI in the cold (Perkin, *C. J.* 89, 429). Aqueous Na_2CO_3 forms $C_6H_4(OMe).CH:CH_2$ and CO_2 .

iodo-METHANE v. **METHYL IODIDE**.

Di-iodo-methane v. **METHYLENE IODIDE**.

Tri-iodo-methane v. **iodoform**.

Tetra-iodo-methane CI_4 . *Carbon tetra-iodide*. S.G. 22 4.82. Formed by mixing CCl_4 with aluminium iodide dissolved in CS_2 (Gustavson, *A.* 172, 173; *C. R.* 78, 882). Formed also by heating CCl_4 with CaI_2 3½ aq at 75° (Spindler, *A.* 231, 264). Dark-red regular octahedra (Friedel, *B.* [2] 21, 482). Sol. CS_2 , alcohol, ether, and MeI . May be kept for some days, but gradually decomposes. The decomposition is hastened by both CS_2 and CO_2 . Above 80° it quickly splits up into carbon and iodine. Converted into iodoform by boiling with aqueous HI, and even by boiling with water. Scarcely attacked by aqueous potash or H_2SO_4 . Chlorine converts it into CCl_4 . Br gives CBr_4 .

iodo-DI-METHYL-AMINE v. *Di-methyl-iodo-amine* under **DI-METHYL-AMINE**.

iodo-DI-METHYL-ANILINE $C_8H_8IN_2$ i.e. $C_6H_4I.NMe_2$. [79°]. Formed by adding iodine to a solution of di-methyl-aniline in OS_2 (Weber, *B.* 10, 765). Formed also by the action of cyanogen iodide on di-methyl-aniline in the cold, heat being evolved and HCl given off (Merz & Weith, *B.* 10, 357). White laminæ, sol. alcohol

and HCl aq. Not attacked by caustic soda. When heated above 80° it gives off HI and leaves a residue which forms a deep violet solution in alcohol.— $B^+H_2P^+Cl_2$.

iodo-TRI-METHYL-BENZENE v. **iodo-CUMENE**.

iodo-METHYL-BUTYL-BENZENE v. **iodo-BUTYL-TOLUENE**.

DI-iodo-METHYLENE DI-ETHYL DI-SULPHONE $Cl_2(SO_2Et)_2$. [177°]. Formed from methylene di-ethyl di-sulphone, I, and $KIAq$, by exposure to sunlight (Fromm, *J.* 253, 161). Needles, sl. sol. boiling water.

DI-iodo-DI-METHYL OXIDE $C_2H_4I_2O$ i.e. $(CH_2I)_2O$. (219°). From dry 'oxymethylene' (formic paraldehyde) and gaseous HI (Tishchenko, *J. R.* 1887, 464). Oil.

iodo-TRI-METHYL-PIPERIDINE $C_8H_{11}IN$. [60°]. Formed by heating ethyldene diacetone with HI (E. Fischer, *B.* 17, 1796). Colourless rectangular prisms. Nearly insol. water— CHI : very sparingly soluble.

Iodo-tetra-methyl-piperidine $C_8H_{11}NI$. [90°]. Formed by heating triacetone with HI at 150° (E. Fischer, *B.* 17, 1791). Easily soluble in alcohol and ether, insol. water. Colourless tables (from ether).

iodo-DI-METHYL-THIOPHENE C_8H_8IS i.e. $CI:CMe$

$CH:CMe$ S. (97°). From di-methyl-thiophene (from coal tar), iodine, and HgO (Messinger, *B.* 18, 1638). Oil.

Iodo-tri-methyl-thiophene C_8H_8IS i.e. $CMe:CMe$

$CI:CMe$ S. Formed by the action of iodine (48 g.) and HgO (21 g.) on tri-methyl-thiophene (12 g.) dissolved in ligroin (24 g.) (Zelinsky, *B.* 21, 1837). Non-volatile oil.

(a) **iodo-NAPHTHALENE** $C_{10}H_7I$. (805°). *Formation*.—1. By adding iodine to a solution of mercury di-naphthyl: $Hg(C_{10}H_7)_2 + 2I_2 = HgI_2 + 2C_{10}H_7I$ (Otto, *A.* 147, 173).—2. From diazo-naphthalene sulphate and HI (Nöling, *B.* 19, 135).

Properties.—Thick yellowish oil, not solidified at -17° . Miscible with alcohol, ether, CS_2 , and benzene. Alcoholic potash at 180° forms some naphthalene. Boiling $HIAq$ (127°) completely converts it into naphthalene. When a solution in CS_2 is boiled with aluminium chloride there is formed naphthalene, iodine, and tarry matter, but no (b)-iodo-naphthalene (Roux, *B.* [2] 48, 512).

Picric acid compound [127°]. Golden yellow needles.

(b) **iodo-naphthalene** $C_{10}H_7I$. [55°]. Prepared by the action of HI on (b)-diazo-naphthalene sulphate (P. Jacobson, *B.* 14, 804). Colourless plates; sol. ether, alcohol, and $HOAc$. Volatile with steam.

(a, a') **Di-iodo-naphthalene** $C_{10}H_6I_2$. [141°]. [110°]. From (a)-iodo-(a')-nitro-naphthalene by reduction, and treatment of the resulting iodo-naphthylamine with H_2SO_4 and $NaNO_2$, followed by HCl (Meldola, *C. J.* 47, 522). Needles (from alcohol).

(a, b') **Di-iodo-naphthalene** $C_{10}H_6I_2$. [81°]. From (b)-iodo-(a')-nitro-naphthalene in

IODO-NITRO-BENZENE

the same way as the preceding (Meldola). Scales (from alcohol).

(8) - IODO- β -NAPHTHALENE SULPHONIC ACIDS $C_{10}H_7ISO_3H$. Two isomerides are formed by sulphonating (8)-iodo-naphthalene (Armstrong & Wynne, *J. Proc.* 3, 22). One of the isomerides forms the salts KA' aq and BaA' , 4aq, both crystallising in hexagonal scales, the other forms the salts KA' aq crystallising in laminae, and BaA' , 2aq in flat needles.

(1, 5)-Iodo-naphthalene sulphonic acid $C_{10}H_7I(SO_3H)$ [1:5]. [129°]. Formed from (a)-diazonaphthalene sulphonic acid and warm $MLAq$ (40 p.c.) (Mauzelius, *B.* 22, 2820). Colourless tables (containing 2aq): v. sol. water.

Salts.— $A'K$ aq: plates; m. sol. water.— $A'Na$ aq: indistinct needles.— $A'Ag$: plates; S. 66.— $A'Ca$ 2aq: scales; sl. sol. water.— $A'Ba$ aq: scales; S. 23 (in the cold). S. 1 at 100°.— $A'Mg$: needles; sl. sol. water.— $A'Zn$ 4aq: scales; m. sol. water.— $A'Cu$ 4aq: greenish-white needles; sl. sol. water.— $A'Pb$ 4aq: sl. sol. water.— $A'Mn$ 4aq: indistinct crystals; sl. sol. water.

Methyl-ether MeA' . [60°]. Prisms: v. sol. Et_2O ; sl. sol. cold $EtOH$.

Ethyl-ether EA' . [74°]. Six-sided tables: v. sol. Et_2O .

n-Propyl-ether PrA' . [67°]. Colourless tables.

Isopropyl-ether PrA' . [90°]. Prisms.

Chloride $C_6H_4ISO_2Cl$. [114°]. Monoclinic prisms: v. sol. hot $AcOH$; sl. sol. ligroin.

Bromide [153°]. Prisms.

Amide $C_6H_4I(SO_2NH_2)$. [239°]. Scales.

(a)-IODO-(β)-NAPHTHOL $C_{10}H_7I(OH)$ [1:2] [94.5°] (M.); [c. 100°] (W.). Prepared by dissolving equal parts (20 g.) of (β)-naphthol, lead acetate, and dried sodium acetate in $HOAc$, cooling, and gradually adding iodine (35.2 g.) dissolved in hot $HOAc$. The product is ppt. by water and recrystallised from dilute alcohol (Meldola, *C. J.* 47, 527). Formed also by the action of iodide of nitrogen on a dilute alcoholic solution of sodium (β)-naphthol (Willgerodt, *J. pr.* [2] 87, 448).

Properties.—Long colourless needles; sl. sol. boiling water; v. sol. organic solvents. Volatile with steam. Sol. cold dilute $KOHAq$; decomposed by hot alkalis. Nitric acid liberates iodine. $KMnO_4$ gives phthalic acid.

(a)-IODO-(a)-NAPHTHYLAMINE $C_{10}H_7I(NH_2)$ [4:1]. From (a)-iodo-(a)-nitro-naphthalene, king-dust, and $HOAc$ (Meldola, *C. J.* 47, 521). Its solution rapidly oxidises in the air forming a red colouring matter.— $B'H_2SO_4$: tolerably stable white needles.

Acetyl derivative $C_{10}H_7I(NHAc)$. [192°]. From the preceding by boiling with Ac_2O (M.). Needles (from alcohol). Gives a nitro-derivative [286°].

IODO-o-NITRO-ANILINE $C_6H_4I(NO_2)(NH_2)$ [5:2:1]. Formed by heating di-iodo-nitro-benzene [168°] with alcoholic NH_3 at 170° for several days (Körner, *G.* 4, 886). Large steel-blue laminae (from alcohol in sealed tubes), yellow by transmitted light. Does not melt at 220°. Not attacked by nitrous ether.

Iodo-o-nitro-aniline $C_6H_4I(NO_2)(NH_2)$ [4:2:1]. [123°]. Formed by warming a solution of the acetyl derivative of p-iodo-aniline in $HOAc$ with

HNO_3 (Michael & Norton, *B.* 11, 109). Long orange-yellow needles (from alcohol).

Iodo-p-nitro-aniline $C_6H_4I(NO_2)(NH_2)$ [2:4:1] [105.5°]. Prepared by the action of iodine chloride (2 pts.) on p-nitro-aniline (1 pt.) dissolved in dilute $HClAq$ (Michael & Norton, *Zm.* 1, 262; *B.* 11, 118). Long yellow needles.— $B'HCl$ [163°].

Di-iodo-m-nitro-aniline $C_6H_3I_2(NO_2)(NH_2)$ [4:2:6:1]. [145.5°]. Formed by passing iodine chloride (3 pts.) into a solution of m-nitro-aniline (1 pt.) in $HClAq$ (Michael & Norton, *Zm.* 1, 255; *B.* 11, 112). Long slender yellow needles, v. sol. cold alcohol, sl. sol. acetic ether, insol. water. Its hydrochloride is not decomposed by water.

Di-iodo-p-nitro-aniline $C_6H_3I_2(NO_2)(NH_2)$ [6:2:4:1]. [244°]. Prepared by the action of iodine chloride (2 mols.) on p-nitro-aniline dissolved in chloroform (M. & N.). Yellow prisms with blue fluorescence (from alcohol). Sl. sol. hot alcohol, sol. $CHCl_3$ and $EtOAc$, v. sol. hot nitro-benzene. It is not basic.

o-IODO-NITRO-BENZENE $C_6H_4I(NO_2)$ [1:2]. [49°]. Formed, together with the p-isomeride, by treating iodo-benzene with HNO_3 (Körner, *G.* 4, 305). The p-isomeride crystallises first from alcohol. Long flat lemon-yellow needles. Gives a little o-iodo-aniline and much aniline on reduction.

m-Iodo-nitro-benzene $C_6H_4I(NO_2)$ [1:3]. [36°]. (c. 280°). Formed from m-nitro-aniline by displacing NH_2 by I through the diazo-reaction (Griess, *Z.* 1866, 218). Monoclinic plates; $a:b:c = 2.296:1.1129$ (Panbianco, *G.* 9, 860). The same body is perhaps formed by the action of ICl on sodium m-nitro-benzoate (Schützenberger & Segenwald, *Rep. Chim. pure*, 1862, 144).

p-Iodo-nitro-benzene $C_6H_4I(NO_2)$ [1:4]. [171°]. The chief product of the action of fuming HNO_3 upon iodo-benzene (Kekulé, *A.* 137, 129). Obtained also from p-nitro-aniline by the diazo-reaction. Pale yellow needles.

Di-chloride $C_6H_3I_2(NO_2)Cl_2$. Formed by passing Cl into a solution of iodo-nitro-benzene in chloroform (C. Willgerodt, *J. pr.* [2] 33, 160). Hardly sol. CS_2 , Et_2O , or light petroleum. Sol. $CHCl_3$ and benzene. At 150° it gives off Cl_2 , leaving $C_6H_3I_2(NO_2)I$. With alcohol it reacts forming aldehyde, HCl and $C_6H_3I_2(NO_2)I$.

Iodo-di-nitro-benzene $C_6H_3I_2(NO_2)_2$ [1:2:4]. [200°]. Obtained by nitrating o- or p-iodo-nitro-benzene with H_2SO_4 and HNO_3 (Körner, *J.* 1875, 823). Yellow triclinic crystals, $a:b:c = 1.634:1.940$ (La Valle, *G.* 10, 3). V. sl. sol. cold alcohol. Hot dilute KOH forms di-nitro-phenol. Alcoholic NH_3 gives di-nitro-aniline, though the decomposition is incomplete in the cold.

Iodo-di-nitro-benzene $C_6H_3I_2(NO_2)_2$ [1:2:6]. [114°]. Formed in small quantity, together with the preceding, by treating o-iodo-nitro-benzene with HNO_3 mixed with H_2SO_4 (Körner, *G.* 4, 805). Orange triclinic tables (from alcohol). More sol. alcohol and ether than the preceding. Converted by heating with alcoholic NH_3 into di-nitro-aniline [188°]. May be reduced to phenylene-m-diamine.

Iodo-tri-nitro-benzene $C_6H_2I_3(NO_2)_3$ [1:2:4:6]. [164°]. From chloro-tri-nitro-benzene and alcoholic KI (Hepp, *A.* 215, 861). Golden needles.

Converted by boiling aqueous KOH into picric acid.

Di-iodo-nitro-benzene $C_6H_3I_2(NO_2)$ [1:3:4]. [168°]. * Obtained from *m*-di-iodo-benzene by dissolving in hot fuming HNO_3 (Körner). Trimetric octahedra; $a:b:c = 647:1:458$ (La Valle, *G.* 10, 2). Sl. sol. ether, v. sl. sol. cold alcohol. By heating for a few days with alcoholic NH_3 at 170° it forms iodo-nitro-aniline.

Di-iodo-nitro-benzene $C_6H_3I_2(NO_2)$ [1:2:4?]. [112-5°]. Formed by dissolving *o*-di-iodo-benzene in fuming HNO_3 and, after a few minutes, diluting with water (Körner a. Wender, *G.* 17, 491). Lemon-yellow needles or small prisms (from alcohol).

(α)-iodo-nitro-benzic acid $C_6H_4INO_2$, i.e. $C_6H_3I(NO_2)(CO_2H)$ [3:2or6:1]. [235°]. Formed, together with the two following, by heating *m*-iodo-benzoic acid with conc. HNO_3 (Grothe, *J. pr.* [2] 18, 324; Cunze a. Hübner, *A.* 135, 106). Sl. sol. water, especially if HCl be present. — Gives *o*-amido-benzoic acid on reduction. NH_4A' aq. — NaA' 3aq. — CaA' 2aq. — SrA' 4aq. — BaA' 3aq.

Ethyl ether EtA' . [84°].
(β)-iodo-nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [3:6or2:1]. [174°]. Formed as above. V. sol. water, especially if HCl be present. Melts under water. May be reduced to *o*-amido-benzoic acid. — NH_4A' aq. — LiA' aq. — NaA' 4aq. — KA' 3aq. — CaA' — SrA' — BaA' 6aq.

Ethyl ether EtA' . [64°]. Yellow plates.
(γ)-iodo-nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [3:1:1]. [192°]. Formed as above. V. sol. water, but does not melt under it. — NaA' aq.: silky yellow needles. — CaA' 3aq. — SrA' 4aq. — BaA' 3aq.

Iodo-nitro-benzoic acid $C_6H_3I(NO_2)(CO_2H)$ [4:3:1]. [210°]. Formed by heating *p*-iodo-benzoic acid with fuming HNO_3 (Glassner, *B.* 8, 562). Nearly insol. water, v. sol. alcohol. — NaA' aq. — KA' aq. — CaA' 1aq.

(α, β)-iodo-nitro-naphthalene $C_{10}H_7I_2(NO_2)$ [4:1]. [123°]. Formed from acetyl-(α)-naphthylamine by nitration, saponification, diazotisation, and treatment with HI (Meldola, *C. J.* 47, 519). Minute white needles (from hot alcohol). Sol. benzene, HOAc, and acetone. May be reduced to (α)-naphthylamine.

(α, β)-iodo-nitro-naphthalene $C_{10}H_7I_2(NO_2)$ [1:2]. [108-5°]. Formed from the mother-liquor of the preceding (Meldola). Yellow scales. May be reduced to (β)-naphthylamine.

(β, α)-iodo-nitro-naphthalene $C_{10}H_7I_2(NO_2)$ [2:1]. [88-5°]. From acetyl-(α)-nitro-(β)-naphthylamine by saponifying with hot dilute H_2SO_4 , and subsequent displacement of NH_2 by I (Meldola, *C. J.* 47, 520).

(α)-iodo-(β)-nitro-(α)-naphthol $C_{10}H_6I(NO_2)(OH)$ [4:2:1]. [146°]. Formed by boiling acetyl (4, 2, 1)-iodo-nitro-naphthylamine with strong caustic alkali (Meldola, *C. J.* 47, 524). Yellow needles (from alcohol). Insol. cold water, sl. sol. hot water and hot benzene, v. sol. alcohol, acetic acid, and acetone. Yields phthalic acid on oxidation. Its K and Na derivatives form minute orange needles, m. sol. cold water. — $\{C_{10}H_6I(NO_2)\}_2$ Ba 3aq.: bright red amorphous powder, almost insol. boiling water; deflagrates on ignition.

(α)-iodo-(β)-nitro-(α)-naphthylamine. *Acetyl derivative* [4:2:1]. [236°]. From acetyl-iodo-naphthylamine by warming its solution in HOAc with HNO_3 at 75° (Meldola, *C. J.* 47, 524). Straw-coloured needles (from alcohol). Sublimes while melting. More difficult to saponify by H_2SO_4 than the bromo-compound.

iodo-nitro-*o*-oxy-benzoic acid $C_6H_3INO_2$, i.e. $C_6H_3I(NO_2)(OH)(CO_2H)$. From (5, 2, 1)-nitro-oxy-benzoic acid by treatment in alcoholic solution with I and HgO (Weselsky, *A.* 174, 108). Slender yellow needles. — KA' 2aq. — $C_6H_3K_2NO_2$ 3aq. — BaA' 6aq.

• Iodo-nitro-*o*-oxy-benzoic acid $C_6H_3I(NO_2)(OH)(CO_2H)$. [204°]. From (5, 2, 1)-iodo-oxy-benzoic acid by nitration (Hübner, *B.* 12, 1347).

Iodo-nitro-*m*-oxy-benzoic acid $C_6H_3I(NO_2)(OH)(CO_2H)$. Formed by treating an alcoholic solution of nitro-*m*-oxy-benzoic acid with I and HgO (Weselsky, *A.* 174, 109). Lemon-yellow crystals; sl. sol. water, v. sol. cold alcohol. — BaA' 6aq.: minute red needles.

Iodo-nitro-*p*-oxy-benzoic acid $C_6H_3I(NO_2)(OH)(CO_2H)$. From nitro-*p*-oxy-benzoic acid, iodine, and HgO (W.). Lemon-yellow needles. — BaA' 4aq.: flat red needles. $BaC_6H_3INO_2$ 2aq.: short dark-red needles.

DI-iodo-di-nitro-di-oxy-di-phenyl sulphone $C_{12}H_8I_2N_2SO_2$, i.e. $SO_2(C_6H_4I(NO_2)OH)_2$. [205°]. Formed by heating iodine (50 g.) dissolved in alcohol with a mixture of di-nitro-di-oxy-di-phenyl sulphone (34 g.) and HgO (21.6 g.) at 100° (Annheim, *B.* 9, 660). Needles (from HOAc); insol. water and alcohol. Decomposes alkaline carbonates. — $Na_2C_{12}H_8I_2N_2SO_2$ 2aq.

iodo-*o*-nitro-phenol $C_6H_4INO_2$, i.e. $C_6H_3I(NO_2)(OH)$. [110°] (Armstrong, *Watts' Dict.* Ed. 1. *Suppl.* 2, 917; *B.* 6, 649). Formed by the action of iodine and HgO on *o*-nitro-phenol dissolved in HOAc (Busch, *B.* 7, 462; cf. Armstrong). Short yellow needles, v. sol. hot water, alcohol, and ether. Moderately volatile with steam. — KA' aq.: garnet-red plates with green lustre (A.), v. e. sol. hot water and alcohol.

Iodo-*p*-nitro-phenol $C_6H_4I(NO_2)(OH)$ [2:4:1]. [93°] (Körner; Armstrong). Formed by the action of iodine and HgO on *p*-nitro-phenol dissolved in HOAc (Körner, *Bull. Acad. Belg.* [2] 24, 166; Busch, *B.* 7, 462). Also from nitro-amido-phenol by the diazo-reaction (K.). Yellow needles. — NaA' 2aq (K.). — KA' 3aq (B.). Nitric acid converts it into iodo-di-nitro-phenol [106°].

Iodo-di-nitro-phenol $C_6H_3I(NO_2)_2(OH)$ [6:4:2:1]. [106°] (A.); [108°] (W.). Formed from (4, 2, 1)-di-nitro-phenol by treatment with iodine, potassium iodate, and potash (Körner, *G.* 4, 397) or with iodine and HgO (Armstrong, *B.* 6, 649; Weselsky, *A.* 174, 111). Formed also from di-nitro-amido-phenol by the diazo-reaction (A.), and by the nitration of the preceding iodo-nitro-phenol (A.). Long slender lemon-yellow needles (from hot water). Sl. sol. hot water. — KA' : deep orange needles, v. sol. hot, sl. sol. cold, water. — CaA' 5aq.: orange-red plates, v. sol. hot water.

Iodo-di-nitro-phenol $C_6H_3I(NO_2)_2(OH)$ [4:6:2:1]. [118°]. Formed from (6, 2, 1)-di-nitro-phenol by treatment with iodine

and iodic acid (Körner, *G.* 4, 397) or with iodine and H_2O (Armstrong, *B.* 6, 649). Long, lemon-yellow needles (from water); v. sl. sol. water and alcohol. The potassium derivative forms magnificent crimson needles with green and golden lustre; sl. sol. water. The silver derivative forms small brownish-red needles.

Di-iodo-o-nitro-phenol
 $\text{C}_6\text{H}_3\text{I}_2(\text{NO}_2)(\text{OH})$ [6:4:2:1]. [98°]. From o-nitro-phenol, iodine, and iodic acid in alkaline solution (Körner). Slender dark-yellow needles (from ether-alcohol); sl. sol. water, v. sol. boiling alcohol and ether.— Na^+aq : dark-brown prisms, with golden lustre.— K^+aq : very soluble reddish-brown needles.

Di-iodo-p-nitro-phenol
 $\text{C}_6\text{H}_3\text{I}_2(\text{NO}_2)(\text{OH})$ [6:2:4:1]. [157°] (K.). From p-nitro-phenol, iodine, KIO_3 , and potash (K.; cf. Seifert, *J. pr.* [2] 28, 437). Also from p-nitro-phenol o-sulphonic acid, iodine in alcoholic solution, and HgO (Post a. Brackebusch, *A.* 205, 91). Formed also by treating nitro-o-oxy-benzoic acid with iodine and HgO (Weselsky, *A.* 174, 107). Large colourless prisms (from ether) turning yellow on exposure to air. Decomposes a little above its melting-point.— K^+aq : golden needles with violet iridescence.— Na^+aq : efflorescent orange laminae.

Di-iodo-nitro-phenols appear also to have been obtained by Piria (*A.* 198, 268).

iodo-NITRO-PHENOL SULPHONIC ACID
 $\text{C}_6\text{H}_3\text{INO}_2$, i.e. $\text{C}_6\text{H}_3\text{I}(\text{NO}_2)(\text{OH})(\text{SO}_3\text{H})$ [2:6:1:4]. Formed when iodine and HgO are added to an alcoholic solution of o-nitro-phenol p-sulphonic acid (Armstrong a. Brown, *C. J.* 25, 869).— K^+aq : yellow scales, composed of short needles, sl. sol. water.— $\text{K}_2\text{C}_6\text{H}_3\text{INO}_2$: red crystals.— Ba^+aq : pale-yellow silky needles, sl. sol. water.

iodo-nitro-phenol sulphonic acid
 $\text{C}_6\text{H}_3\text{I}(\text{NO}_2)(\text{OH})(\text{SO}_3\text{H})$ [6:4:1:2]. Formed, together with di-iodo-p-nitro-phenol, by treating an alcoholic solution of p-nitro-phenol o-sulphonic acid with iodine and mercuric oxide (Post a. Brackebusch, *A.* 205, 88).—Salts.— $\text{CaC}_6\text{H}_3\text{INO}_2$ 3aq: coarse yellow needles, m. sol. water.— $\text{BaC}_6\text{H}_3\text{INO}_2$ 3aq: long yellow needles, m. sol. water.— $\text{Pb}_2(\text{OH})_2\text{C}_6\text{H}_3\text{INO}_2$ 2aq: yellow crystalline pp.

DI-iodo-NITRO-RESORCIN
 $\text{C}_6\text{H}_2\text{I}_2(\text{NO}_2)(\text{OH})_2$. From nitro-resorcin in alcoholic solution by alternate addition of iodine and mercuric oxide (Weselsky, *A.* 174, 111). Golden needles.

iodo-NITRO-THIOPHENE $\text{C}_4\text{H}_3\text{I}(\text{NO}_2)\text{S}$. [74°]. Formed by nitration of iodo-thiophene (Kreiss, *B.* 17, 2073). Glistening yellow prisms.

iodo-NITRO-TOLUENE $\text{C}_7\text{H}_4\text{INO}_2$, i.e. $\text{C}_7\text{H}_3\text{MeI}(\text{NO}_2)$ [1:4:2]. [61°]. (286°). From (4,1)-di-nitro-toluene (Heynemann, *A.* 168, 337). Pale yellowish crystals. V. e. sol. CS_2 and ether.

Iodo-nitro-toluene $\text{C}_7\text{H}_3\text{MeI}(\text{NO}_2)$ [1:4:3]. [56°]. From p-toluidine by nitration and displacement of NH_2 by I (Beilstein a. Kuhlberg, *A.* 153, 844). Large flat needles; v. sol. boiling alcohol.

Iodo-nitro-toluene $\text{C}_7\text{H}_3\text{MeI}(\text{NO}_2)$ [1:2:x]. [104°]. Formed by nitrating o-iodo-toluene (B. a. K.). Minute needles.

Iodo-nitro-toluene (?). [109°]. Formed by nitrating m-iodo-toluene (B. a. K.). Small needles.

Iodo-di-nitro-toluene $\text{C}_7\text{H}_2\text{MeI}(\text{NO}_2)_2$ [1:4:5:3]. [188°]. Formed by nitrating p-iodo-toluene (Glassner, *B.* 8, 561). Crystals.

iodo-OCTINOIC ACID $\text{C}_{11}\text{H}_{11}\text{IO}_2$, i.e. $(\text{C}_6\text{H}_4)_2\text{C}(\text{CO}_2\text{H})\text{I}$. *Iodo-di-allyl-acetic acid*. From $(\text{C}_6\text{H}_5)_2\text{C}(\text{OH})\text{CO}_2\text{H}$ (17 g.) and cold fuming HIAq (45 g.) (Schatzky, *J. R.* 17, 78). Crystals, insol. water, v. sol. alcohol and ether. Easily decomposed.

p-iodo-n-octyl-benzene $\text{C}_{18}\text{H}_{25}\text{I}$ i.e. $\text{C}_8\text{H}_{17}(\text{C}_6\text{H}_4)_2\text{I}$ [1:4]. [319°]. Heavy oil. Formed by diazotising p-amido-phenyl-octane, and treating the diazo-octyl-benzene with HI (Beran, *B.* 18, 136). On oxidation with CrO_3 it gives p-iodo-benzoic acid. Iodo-octyl-benzene obtained by the action of iodine and HgO upon n-octyl-benzene is described by Ahrens (*B.* 19, 2720) as an oil, solidifying at -4° , and completely decomposed by distillation.

p-Iodo-sec-octyl-benzene $\text{C}_{18}\text{H}_{25}\text{I}$ [1:4]. *p-Iodo-capryl-benzene*. (305° uncor.). Formed by diazotising p-amido-phenyl-sec-octane and treating the diazo-capryl-benzene with HI . Heavy oil. V. sol. ether and acetic acid, sl. sol. alcohol. It is oxidised by CrO_3 to p-iodo-benzoic acid (Beran, *B.* 18, 142).

iodo-(n)-OCTYL-THIOPHENE $\text{C}_9\text{H}_{11}\text{IS}$ i.e. $\text{C}_8\text{H}_{10}\text{SI}(\text{C}_4\text{H}_9)$. [c. 0°]. S.G. 1.2614. From octyl-thiophene (10 g.) in ligroin by treatment with iodine (10 g.) and HgO (11 g.) (Schweinitz, *B.* 19, 644). V. sol. ether, cannot be distilled.

iodo-OLEIC ACID v. **iodo-STEARDNIC ACID**.

iodo-ORCIN $\text{C}_8\text{H}_7\text{IO}$, i.e. $\text{C}_8\text{H}_6\text{MeI}(\text{OH})$. [86.5°]. Formed by dissolving orcin (1 pt.) and iodine (2 pts.) in ether (6 pts.), and gradually adding finely powdered litharge (9 pts.). The ether is distilled off, and the residue recrystallised from benzene (Stenhouse, *Pr.* 22, 53). Prisms; decomposing when heated alone or with water. Sl. sol. cold water, v. sol. hot water, alcohol, and ether. Has not the astringent sweet taste of orcin.

Tri-iodo-orcin $\text{C}_8\text{H}_4\text{I}_3\text{O}$, i.e. $\text{C}_8\text{MeI}_3(\text{OH})$. Formed by adding to a dilute aqueous solution of orcin a quantity of ICl_3 , not quite sufficient to ppt. all the orcin, and crystallising the pp. first from CS_2 and then from boiling alcohol (Stenhouse, *C. J.* 17, 527). Large transparent plates, tinged with brown. V. sol. CS_2 , v. e. sol. ether, m. sol. alcohol, insol. water. Becomes brown at 100°. Dissolves with decomposition in aqueous KOH . Decomposed by hot H_2SO_4 and by hot HNO_3 .

Iodo-(8)-orcin v. **iodo-RETORCIN**.

DI-iodo-ORSSELLIC ACID. *Methyl ether* $\text{C}_8\text{H}_7\text{I}_2\text{O}$, i.e. $\text{C}_8\text{H}_6\text{I}_2\text{OMe}$. *Methyl di-iodo-di-oxy-toluene*. Formed by adding a dilute solution of chloride of iodine, containing excess of iodine, to a cold saturated aqueous solution of methyl orsellate (Stenhouse, *A.* 149, 295). Needles from CS_2 ; sol. benzene, CS_2 , alcohol, and boiling water. Decomposed on fusion.

Ethyl ether $\text{C}_8\text{H}_7\text{I}_2\text{O}$. Formed in like manner. Small needles; almost insol. cold water, m. sol. benzene, CS_2 , and boiling alcohol. Decomposed on fusion.

iodo-o-oxy-BENZOIC ACID $\text{C}_7\text{H}_5\text{IO}$, i.e. $\text{C}_6\text{H}_4\text{I}(\text{OH})(\text{CO}_2\text{H})$ [3:2:1]. *Iodo-salicylic acid*. [198°]. Formed, together with the following compound, by boiling a solution of salicylic acid

and iodine in alcohol, and separated by fractionally crystallising the product from water (A. Miller, *O. J.* 41, 406; *A.* 220, 124). Long needles; s. sol. water. Gives a violet colouration with FeCl_3 . Gives the corresponding di-oxy-benzoic acid on potash-fusion.— BaA' , 8:1aq: concentrically grouped needles. S. 5 at 8° .

Iodo-o-oxy-benzoic acid $\text{C}_6\text{H}_4\text{I}(\text{OH})(\text{CO}_2\text{H})$ [5:2:1]. [196°] (G.); [193-5°] (F.); [197°] (M.). S. 11 at 20° ; 1 at 100° (L.).

Formation.—1. As above.—2. Together with di- and tri-iodo-oxy-benzoic acids, by fusing salicylic acid (1 mol.) with iodine (1 mol.) and treating the product with aqueous KOH (Kolbe a. Lautemann, *A.* 115, 157).—3. By dissolving equal weights of iodine and salicylic acid in 80 p.c. alcohol, boiling for 3 hours, evaporating, and dissolving in aqueous Na_2CO_3 (Lautemann, *A.* 120, 299).—4. From salicylic acid, iodine, and HgO (Hlasiwetz a. Weselsky, *B.* 5, 380; *A.* 174, 99).—5. By agitating a hot solution of salicylic acid (1 pt.) in water (25 pts.) with a mixture of iodine (1 pt.) and iodic acid ($\frac{1}{2}$ pt.), keeping the liquid hot for some time. The resulting acid is converted into sodium salt, and the satiny-needles of the salt of the di-iodo-acid separated, if necessary by hand-picking, from the lancet-shaped laminae of the mono-iodo-acid (Liechti, *A. Suppl.* 7, 129; H. Fischer, *A.* 180, 346).—6. From the corresponding nitro-oxy-benzoic acid by reduction to oxy-amido-benzoic acid and exchange of NH_2 for I by the diazo-reaction (Goldberg, *J. pr.* [2] 19, 368; P. F. Frankland, *C. J.* 87, 749).—7. By warming dry silver salicylate with iodine (Birnbach a. Reinherz, *B.* 15, 458).

Properties.—Long needles (from water); sl. sol. water, v. sol. alcohol and ether. Gives a violet colour with FeCl_3 . On potash-fusion at 200° it gives di-oxy-benzoic acid [197°]. When suddenly heated it splits up into CO_2 and iodo-phenol.

Salts.— NaA' 8q. S. 7.7 at 20° (L.).— KA' 3aq: laminae. S. 19 at 20° (L.).— $\text{NH}_4\text{A}'$ 8:1aq: needles. S. 9.5 at 20° (L.).— BaA' , 4aq: warty scales. S. (of BaA') 8 at 8° (M.); 1:3 at 20° (L.).— BaOHI_2 , 2aq: tufts of small needles (L.).— CaA' , 6aq.— MgA' , 6aq.— PbA' .— AgA' : yellowish pp.

Ethyl ether EtA'. [71°] (Sohmitt, *Z.* 1864, 221).

Iodo-m-oxy-benzoic acid $\text{C}_6\text{H}_3\text{I}(\text{OH})(\text{CO}_2\text{H})$ [3:3:1]. Formed, together with di-iodo-phenol, by alternately adding iodine and HgO to oxy-benzoic acid dissolved in 90 p.c. alcohol, and separated by solution in boiling water (Weselsky, *A.* 174, 99). Slender needles; sl. sol. cold water.

Iodo-p-oxy-benzoic acid $\text{C}_6\text{H}_3\text{I}(\text{OH})(\text{CO}_2\text{H})$ [3:4:1]. [160°] (P.). S. 18 in the cold.

Formation.—1. By boiling a solution of p-oxy-benzoic acid for a few minutes with iodine and iodic acid (Peltzer, *A.* 146, 288).—2. From p-oxy-benzoic acid dissolved in alcohol by alternate addition of iodine and HgO (Weselsky, *A.* 174, 99).

Properties.—Small needles (from water). Decomposes at 192° . May be sublimed below its melting-point. V. e. sol. alcohol and ether. Gives with FeCl_3 a dingy brown pp.

Salts.— NaA' 6aq: monoclinic efflorescent crystals.— Na , $\text{C}_6\text{H}_3\text{I}_2\text{O}_6$ 6aq: hygroscopic silky

needles (from alcohol).— BaA' , 7aq: trimetric tables.— AgA' : white pp.

Methyl derivative $\text{C}_6\text{H}_3\text{I}(\text{OMe})(\text{CO}_2\text{H})$. **Iodo-anisic acid**. [235°]. S. (cold ether) 7. Formed by heating anisic acid with iodine and iodic acid at 150° (P.). Formed also by oxidation of the methyl ether of iodo-p-cresol (Schall a. Dralle, *B.* 17, 2533). The same, or an isomeric acid, is formed from amido-anisic acid by the diazo-reaction (Griess, *Fr.* 10, 309). Plates (S. a. D.) or needles (G.). Nearly insol. boiling water, m. sol. alcohol.— NaA' 2aq: apocentrically grouped needles.— BaA' , 8aq: vitreous prisms.— CaA' , 8aq: nacreous laminae.— PbA' (at 100°): curdy pp.— AgA' : micro-crystalline laminae.

Di-iodo-o-oxy-benzoic acid $\text{C}_6\text{H}_2\text{I}_2(\text{OH})(\text{CO}_2\text{H})$. **Di-iodo-salicylic acid**. S. 0.7 at 15° ; 15 at 100° (L.). Formed, together with iodo-o-oxy-benzoic acid, by the action of iodine and aqueous potash, of iodine and iodic acid, or of iodine and HgO upon salicylic acid (Lautemann, *A.* 120, 304; Liechti, *A. Suppl.* 7, 141; Demole, *B.* 7, 1439; Weselsky, *A.* 174, 103). Formed also by heating dry silver salicylate with iodine (Birnbach a. Reinherz, *B.* 15, 459). White felted mass (from hot water). V. sol. alcohol and ether. At 197° (L.) or 220° (W.) it begins to decompose, giving off iodine. It gives a violet colouration with FeCl_3 . On potash-fusion it gives tri-oxy-benzoic (? gallic) acid and pyrogallol.

Salts.— NaA' 2:1aq: long flat needles, mostly grouped in druses. S. 2 at 20° ; much less soluble in water than iodo-o-oxy-benzoic acid.— KA' 1:1aq: minute thick prisms. S. 5.53 at 20° . V. sol. alcohol, sl. sol. ether.— $\text{NH}_4\text{A}'$ 1:1aq: arborescent groups of small needles. S. 32 at 20° .— BaA' , 3aq: needles. S. 0.74 at 18° . V. sl. sol. alcohol.— $\text{BaC}_6\text{H}_3\text{I}_2\text{O}_6$, 1:1aq: small silky tablets, v. sl. sol. water, forming an alkaline solution.— CaA' , 5aq: needles. S. 0.86 at 25° .

Di-iodo-p-oxy-benzoic acid $\text{C}_6\text{H}_2\text{I}_2(\text{OH})(\text{CO}_2\text{H})$. Formed, together with iodo-p-oxy-benzoic acid, by iodation of p-oxy-benzoic acid (Peltzer). Small needles (from dilute alcohol). Nearly insol. boiling water, v. e. sol. alcohol and ether. Decomposes when heated without previous fusion. Cannot be sublimed.— NaA' 7aq: tufts of delicate, iridescent, efflorescent needles, v. sol. water.— Na , $\text{C}_6\text{H}_2\text{I}_2\text{O}_6$ 6aq: trimetric tables.— BaA' : gelatinous pp. got by adding alcohol to its aqueous solution.— CaA' , 2aq: nacreous laminae.— PbA' : bulky pp. Swells up like mercuric sulphocyanide when heated.— AgA' .— $\text{Ag}_2\text{C}_6\text{H}_2\text{I}_2\text{O}_6$.

Tri-iodo-o-oxy-benzoic acid $\text{C}_6\text{H}_1\text{I}_3(\text{OH})(\text{CO}_2\text{H})$. [157°]. Obtained in small quantity in preparing mono-, and di-iodo-o-oxy-benzoic acids by the action of iodine and KOH on salicylic acid (Lautemann). Weselsky (*A.* 174, 104) could not obtain it by treating salicylic acid with iodine and HgO . Tufts of needles (from alcohol). Insol. water, sol. alcohol and ether. Decomposed by alkalis into CO_2 and a red body $\text{C}_6\text{H}_1\text{I}_3\text{O}$ (?). Its sodium salt is a grey-green mass, v. sl. sol. water.

IODO-P-OXY-BENZOIC ALDEHYDE $\text{C}_6\text{H}_3\text{IO}$, i.e. $\text{C}_6\text{H}_3\text{I}(\text{OH}).\text{CHO}$. [199°]. Formed by heating the dilute alcoholic solution of p-oxy-benzoic aldehyde with iodine for some hours (Hersfeld, *B.* 10, 2196). Sl. sol. water and benzene, v. sol.

alcohol and ether. Converted by potash-fusion into protocatechuic acid.

Iodo-di-oxy-benzoic aldehyde. *Methyl derivative* $C_6H_4IO_2$, i.e. $C_6H_4I(OH)(OMe)CHO$. *Iodo-vanillin*. [174°]. Formed by warming vanillin with an alcoholic solution of iodine (Carles, *Bl.* [2] 17, 12). Needles. Sol. cold alcohol and ether.

Di-iodo-di-oxy-benzoic aldehyde. *Methyl derivative* $C_6H_2I_2(OH)(OMe)CHO$. Formed like the preceding, using more iodine (C.). Crystals; insol. chloroform, sol. alcohol and ether.

α -IODO- β -OXY-PHENYL-PROPIONIC ACID $C_9H_7IO_3$, i.e. $C_6H_4CH(OH)CH_2CO_2H$. [133°]. Formed by treating cinnamic acid with an aqueous solution of iodine chloride, the compound $C_6H_4CHClCH_2CO_2H$ being probably first formed (Erlenmeyer a. Rosenhek, *B.* 19, 244). Large crystals (from benzene). With HCl it gives the compound C_6H_4CHClO , which may possibly be $C_6H_4CHClCH(OH)CO_2H$.

Exo-Iodo- α -oxy-propionic acid. *Methyl derivative* $C_6H_4(OMe)CH_2CO_2H$. Formed by the combination of the methyl derivative of (a)- or (b)-coumaric acid with HI (Perkin, *C.* 39, 429). Decomposed by aqueous Na_2CO_3 into CO_2 , HI, and $C_6H_4(OMe)C_2H_5$.

TETRA-iodo-di-oxy-di-phenyl SULPHONE $C_{12}H_4I_4SO_2$, i.e. $SO_2(C_6H_4I_2OH)_2$. [260°-270°]. S.G. 2.797. From di-oxy-di-phenyl sulphone by treatment in alcoholic solution with iodine and HgO (Annaheim, *B.* 9, 1150). Minute needles (from HOAc). Decomposes on fusion. Insol. cold alcohol, nearly insol. boiling alcohol and HOAc.

β -IODO- α -OXY-PROPIONIC ACID $C_9H_7IO_3$, i.e. $CH_3CH(OH)CO_2H$. *Iodo-lactic acid*. [101° (M.); 85° (P)]. Formed by treating β -chloro- α -oxy-propionic acid with KI at 50° (Glinsky, *B.* 6, 1257). Prepared by the addition of HI to sodium glycidate (Melikov, *B.* 14, 937). Large prisms, v. sol. water, alcohol, and ether. Converted by alcoholic KOH into glycidic acid.—AgA': white unstable pp.—ZnA': crystalline powder. (M.) or tables (G.).—CaA': 3aq: amorphous (M.).

DI-iodo-oxy-pyridine $C_5H_4N_2IO_2$ [2:4:5] (?). [269°]. Formed by heating an alkaline solution of pyridine di-carboxylic acid (quinolinic acid) with iodine and KI at 180°-200°. Small flat needles. Sol. hot acetic acid and amyl alcohol, v. al. sol. boiling water, alcohol, ether, or chloroform. Dissolves in dilute alkalis.— $C_5H_4N_2(OH)_2$ 8aq: colourless glistening scales, al. sol. aqueous NaOH (Pfeiffer, *B.* 20, 1352).

IODO-(Py. 8)-OXY-QUINOLINE $C_8H_5NOI_2$, i.e. $C_8H_4N(OH)IO_2$ or $C_8H_4N(OH)IO_2$. *Iodo-carboxystil.* [276°]. Formed by boiling α -amide-phenyl-propionic acid $C_8H_4(NH_2)CH_2CO_2H$ with dilute HI (Baeyer a. Böem, *B.* 16, 2149). Sublimable.

DI-iodo-di-oxy-toluic acid v. Di-iodo-oxybenzoic acid.

IODO-PENTANE v. Amyl iodide. **Di-iodo-pentane** $C_5H_{10}I_2$, i.e. $(CH_2CH_2)_3CH_2I_2$ (C. 183°). Formed by heating methylene di-

methyl diketone $(CH_3CO)_2CH_2$ with HI at about 90° (Combes, *A. Ch.* [6] 12, 235). Liquid, begins to decompose at its boiling-point.

IODO-PENTINENE $C_5H_4I_2$, i.e. $(CH_2)_3CH=CHIO_2$ (140°). Formed from the silver derivative of $(CH_2)_3CH=CH$ by treatment with a solution of iodine in KI (Eltekoff, *J. R.* 9, 225). Liquid. Gives $(CH_2)_3CH=CH$ when heated with NaOEt.

DI-iodo-DIPHENIC ACID v. Di-iodo-DIPHENYL DI-CARBOXYLIC ACID.

o -IODO-PHENOL $C_6H_4IO_2$, i.e. [2:1] $C_6H_4I(OH)$. [43°].

Formation.—1. Probably occurs among the products of the iodation of phenol (Schützenberger a. Sengenwald, *C. R.* 54, 197; Körner, *A.* 137, 197; Hlasiwetz a. Weselsky, *Sitz. W.* 60 [2] 290; Lobanoff, *B.* 6, 1251).—2. By the action of iodine on sodium phenol suspended in CS_2 (Schall, *B.* 16, 1897).—3. By heating the chloride or sulphate of o -diazophenol with KI, distilling the product with steam, and recrystallising from water (Nöbling a. Wrzesinsky, *B.* 8, 820; Nöbling a. Stricker, *B.* 20, 8018; *Bl.* [2] 49, 659; Neumann, *A.* 241, 68).—4. By adding powdered iodine to a dilute alcoholic solution of phenol, mixed with ammonia (Willgerodt, *J. pr.* [2] 37, 446).

Properties.—White needles, v. sol. water and other ordinary menstrua. According to Schall (*B.* 20, 3363) it forms in crystalline branches, melting at 43° or needles melting at 40°. Nitric acid attacks it, setting iodine free, but chlorine does not do so, but forms chloro-iodo-phenol. Potash-fusion at 165°-250° yields pyrocatechin. Not affected by air and light. Cold conc. H_2SO_4 produces di-iodo-phenol (Neumann, *B.* 20, 581).

m -Iodo-phenol [3:1] $C_6H_4I(OH)$. [40°]. Prepared from m -iodo-aniline by diazo reaction. The product is distilled with steam, extracted with ether, and recrystallised from ligroin (N. a. S.). It may be prepared in like manner from m -amido-phenol, by diazotising and heating the product with aqueous KI. Needles (from ligroin). May be sublimed. V. sol. alcohol and ether. It does not give off iodine when treated either with HNO_3 or with chlorine. It yields resorcin when fused with KOH.

p -Iodo-phenol [4:1] $C_6H_4I(OH)$. [94°].

Formation.—1. In the iodation of phenol.—2. From p -amido-phenol by diazotising and heating the product with KIO₄ (N. a. S.).—3. A by-product, together with di- and tri-iodo-phenol, in the formation of o -iodo-phenol from iodine, ammonia, and an alcoholic solution of phenol (Willgerodt, *J. pr.* [2] 37, 446).

Properties.—Long needles. Nitric acid sets iodine free, but chlorine does not do so. When heated with conc. H_2SO_4 it gives (1, 3, 6)-di-iodo-phenol [72°]. Potash-fusion gives resorcin at high temperatures.

Di-iodo-phenol $C_6H_3I_2(OH)$ [4:2:1]. [72°]. Formed by mixing o -iodo-phenol (10 g.) with H_2SO_4 (30 g.) at -10° (Neumann, *A.* 241, 71). Formed also in like manner from p -iodo-phenol. White needles (from water). Volatile with steam. Boiling HNO_3 converts it into picric acid.

Acetyl derivative $C_6H_3I_2(OAc)$. [76°]. Long flat trimetric prisms (from dilute alcohol); $a:b:c$ = 731:1:832.

Di-iodo-phenol $C_6H_4I_2(OH)$ [68°]. Formed as a by-product in the action of iodine upon phenol-sodium suspended in CS_2 (Schall, *B.* 16, 1899, 1906; 20, 3884). Apparently formed also in the action of iodine chloride on phenol (S. a. S.). White glistening plates. Volatile with steam.— $C_6H_4I_2ONa$: needles.

Acetyl derivative $C_6H_4I_2(OAc)$: [107° uncor.], small prisms.

Benzoyl derivative $C_6H_4I_2(OBz)$: [96° uncor.].

Di-iodo-phenol $C_6H_4I_2(OH)$. [150°]. Formed by the action of iodine and HgO on an alcoholic solution of phenol (Hlasiwetz a. Weselsky, *Sitz. W.* 60 [2] 290; *C.* 120, 307, 63). Silky felted needles (from dilute alcohol); v. sol. alcohol, ether, and CS_2 . May be sublimed. Not affected by boiling alcoholic KOH .

Tri-iodo-phenol $C_6H_3I_3(OH)$ [6:4:2:1]. [155°].

Formation.—1. By treating phenol with a considerable quantity of ICl , and exhausting the product with boiling alcohol in which tri-iodo-phenol is not very soluble (Schützenberger, *Bl.* 4, 102).—2. From phenol, iodine, and KOH (Lautemann, *A.* 120, 307).—3. From phenol, iodine, and iodic acid (Körner, *A.* 137, 213).—4. From salicylic acid, iodine and iodic acid (Kekulé, *A.* 131, 231).—5. Formed as a by-product from the action of iodine on phenol-sodium suspended in CS_2 (Schall, *B.* 16, 1899).—6. By the action of iodide of nitrogen on a dilute alcoholic solution of sodium phenolate (Willgerodt, *J. pr.* [2] 37, 447).

Properties.—Needles (from dilute alcohol). Decomposed on fusion. M. sol. alcohol. Converted by excess of ICl into per-chloro-phenol. HNO_3 gives picric acid. HCl and $KClO_3$ give chloranil.

DI-iodo-PHENOL SULPHONIC ACID

$C_6H_3I_2(OH)(SO_3H)$ [6:2:1:4]. [120°]. Formed by adding a solution of KI and KIO_3 to one of phenol *p*-sulphonic acid in aqueous HCl (Kehrmann, *J. pr.* [2] 37, 11, 334, 359; Ostermayer, *J. pr.* [2] 37, 215). Monoclinic prisms, v. e. sol. water, but *ppd.* by HCl or H_2SO_4 , decomposes at 190°. Converted by nitric acid into picric acid. Chromic acid oxidises it to di-iodo-quinone.

Salts.— KA' 2aq: long needles or thick prisms.— NaA' 8aq: sol. water, commercially known as 'sozodole'.— $C_6H_3K_2I_2SO_3$: dimetric prisms.— BaA' 8aq: shining needles, v. sl. sol. water.— ZnA' 6aq: long needles. The copper salt is greenish-white and v. sol. water.

DI-*p*-iodo-DIPHENYL- $C_6H_4I_2$, i.e.

$C_{12}H_8I_2$ [202°]. Formed by the action of HI on the diazo-compound derived from benzidine (Schmidt a. Schultz, *B.* 12, 489). Yellow leaflets.

o-iodo-PHENYL-ACETIC ACID $C_6H_4IO_2$, i.e.

$C_6H_4ICH_2CO_2H$ [98°]. Prepared by digesting its nitrile with fuming HCl for four hours at 120°. The nitrile is formed by treating *o*-iodo-benzyl bromide with KCy (Mabery a. Robinson, *Am. J.* 4, 102). Slender needles (from water), sol. hot water, alcohol, ether, CS_2 , and ligroin.— AgA' : curdy pp.; sl. sol. water.

***p*-Iodo-phenyl-acetic acid** $C_6H_4ICH_2CO_2H$ [185°]. Prepared by heating its nitrile with fuming $HClAq$ in sealed tubes at 100° (Jackson, *a. Mabery, Am. J.* 2, 253; *P. Am. J.* 13, 205; *B.* 11, 56). Narrow white plates (from water) with

agreeable odour like sweet allysium; v. sol. hot water, alcohol, ether, benzene, and CS_2 . Gives *p*-iodo-benzoic acid on oxidation.— BaA' : aq: minute white needles, v. sol. water.— AgA' : glistening plates, sl. sol. boiling water.

Nitrile $C_6H_4ICH_2CN$. *p*-Iodo-benzyl cyanide. [50-5°]. Prepared by boiling *p*-iodo-benzyl bromide with alcoholic KCy . Pearly plates, insol. water, v. sol. alcohol, ether, and CS_2 .

iodo-PHENYL-ACETYLENE $C_6H_4ICH_2C\equiv CH$. Obtained from phenyl-acetylene (Holleman, *B.* 20, 3080). Brownish-yellow liquid.

iodo-PHENYL-ACRYLIC ACID v. Iodo-CHROMIC ACID.

***Exo*-iodo-DI-PHENYL-AMYLIDENE-DIAMINE** $C_{12}H_{16}N_2$, i.e. $C_6H_5I(NHPh)_2$. Formed by heating iodo-isovaleric aldehyde with aniline (Chantard, *A. Ch.* [6] 16, 169). Large brownish-yellow needles; v. sol. water and alcohol, m. sol. other solvents. Decomposed on fusion. Forms uncrystallisable salts.

DI-iodo-DIPHENYL-DI-CARBOXYLIC ACID $C_{12}H_8I_2O_4$, i.e. $C_6H_4I(CO_2H)_2$. [262°]. Prepared by the action of HI on the diazo-derivative of di-amido-di-phenyl dicarboxylic acid (Schultz, *B.* 11, 217; *A.* 196, 21; 203, 95). Amorphous; v. sl. sol. boiling water, v. sol. alcohol, acetone, and ether.

DI-iodo-PHENYLENE OXIDE so called. $C_{12}H_8I_2O$. *Tetra-iodo-diphenylene quinone*. Formed in the action of iodine and KOH upon *o*-, *m*-, or *p*-oxy-benzoic acid and on phenol (Lautemann, *A.* 120, 309; Kämmerer a. Benzinger, *B.* 11, 557). Formed also by boiling tri-iodo-phenol with aqueous $Na_2CO_3(L)$, and by distilling di-iodo-diphenyl dicarboxylic acid with lime (Schultz, *B.* 11, 217). Reddish-brown powder, insol. water, alcohol, ether, chloroform, and benzene. Dissolves in CS_2 with deep-red colour. Boiling KOH has little action on it. Conc. HNO_3 forms picric acid. It decomposes at 200°. Aqueous SO_2 at 100° forms colourless $C_{12}H_8I_2O_2$.

DI-*exo*-iodo-DI-PHENYL-ETHYLENE

$C_{12}H_{10}I_2$, i.e. $C_6H_5I(C_6H_4)CH=CH_2$. Formed by heating di-phenyl-acetylene (tolane) with dry iodine and crystallising from chloroform (E. Fischer, *A.* 211, 233). Rose-coloured plates; v. sl. sol. alcohol. Decomposed by heat.

***ω*-iodo-DI-PHENYL-ETHYLIDENE-DIAMINE** $C_{12}H_{14}IN_2$, i.e. $CH_2I.C_6H_4(NHPh)_2$. Obtained by heating iodo-acetic aldehyde with excess of aniline (Chantard, *A. Ch.* [6] 16, 155). Yellow needles or tables. Cannot be melted without decomposition. V. sol. alcohol, sl. ether, benzene and CS_2 . With strong acids it forms uncrystallisable salts, v. sol. water and alcohol.

DI-*p*-iodo-DI-PHENYL-GUANIDINE

$C_{12}H_{10}I_2N_4$, i.e. $CN_2H_2(C_6H_4I)_2$? From *p*-iodo-aniline in ethereal solution and $CyCl$ (Hofmann, *A.* 67, 148). Crystalline.— $B'H_4PbCl$.

Tri-*p*-iodo-tri-phenyl-guanidine $C_{18}H_{12}I_3N_4$. From di-*p*-iodo-di-phenyl-urea and iodine (Losanitsch, *B.* 5, 158).

***Exo*-iodo-DI-PHENYL-HEPTYLIDENE-DIAMINE** $C_{18}H_{24}N_2$ [NH_2CH_2]. Formed by heating iodoheptioic aldehyde with aniline (Chantard, *A. Ch.* [6] 16, 178). Lemon-yellow deliquescent tables; v. sol. alcohol, sl. sol. benzene and $CHCl_3$. Decomposed on heating. Does not give crystalline salts.

p-IODO-PHENYL-HYDRAZINE $C_6H_4I.NH_2$, *i.e.* $C_6H_4I.NH.NH_2$. [103°]. Formed by reducing the diazo-derivative of *p*-iodo-aniline [60°] with an excess of $SnCl_4$ (Neufeld, A. 248, 98). Silky needles (from hot water); v. sol. alcohol, ether, chloroform, benzene, and dilute HOAc. With acetone it forms $C_6H_4I.N_2H.CMe_2$, crystallising from petroleum-ether in white plates [114°]. With acetic aldehyde it gives $C_6H_4I.N_2H.CHMe$ [107°] crystallising from petroleum-ether in yellow needles.

Di-iodo-phenyl-hydrazine $C_6H_3I_2(NH_2)_2$ [4:2:1]. [112°]. From di-iodo-aniline by diazotising and reducing with $SnCl_4$ (Neufeld, A. 248, 99). White silky needles, v. sol. alcohol, ether, and benzene, sl. sol. hot water and petroleum-ether. The hydrochloride [162°] crystallises from water in white needles.

Di-iodo-*s*-di-phenyl-hydrazine $C_{12}H_{10}I_2N_2$, *i.e.* [8:1] $C_6H_4I.NH.NH.C_6H_4I$ [1:3]. *Hydrazo-di-iodo-benzene*. [90°]. Formed by heating the azoxy-compound $C_6H_3I_2N_2O.C_6H_4I$ with alcoholic ammonium sulphide at 100° (Gabriel, B. 9, 1408). V. sol. ordinary solvents.

Di-iodo-*s*-di-phenyl-hydrazine [4:1] $C_6H_4I.NH.NH.C_6H_4I$ [1:4]. Formed by heating the corresponding azoxy-compound with alcoholic ammonium sulphide at 100° (G.). Flat needles; decomposed before melting.

p-IODO-PHENYL-OXAMIC ACID $C_6H_4I.NH.CO.CO_2H$. [c. 200°]. S. 0.72 at 25°. Formed by the action of alcoholic potash on the di-iodo-di-anilide of oxalic acid (Dyer a. Mixter, Am. 8, 857). Long white fibres. Sol. alcohol and ether.—*Baa': white pp.—*Aga': white pp.—KA': sol. hot water.

p-IODO-PHENYL PHTHALIMIDE
 $(1)C=O$
 $C_6H_4 \begin{array}{c} \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} \begin{array}{c} O \\ | \\ (2)C=N.C_6H_4I \end{array}$ [227°–228°]. Prepared by heating *p*-iodo-aniline with phthalic anhydride (Gabriel, B. 11, 2261). Needles. V. sol. C_6H_6 , less sol. ether.

o-IODO-PHENYL-PROPIONIC ACID C_6H_4IO , *i.e.* $C_6H_4I.C_2H_4.CO_2H$. *o*-Iodo-hydrocinnamic acid. [103°]. Plates (from water). Formed by reduction of *o*-iodo-cinnamic acid (Gabriel a. Herzberg, B. 16, 2037).

m-Iodo-phenyl-propionic acid $C_6H_4I.C_2H_4.CO_2H$. *m*-Iodo-hydrocinnamic acid. [68°]. Colourless plates. Formed by reduction of *m*-iodo-cinnamic acid (Gabriel a. Herzberg, B. 16, 2039).

p-Iodo-phenyl-propionic acid $C_6H_4I.C_2H_4.CO_2H$. *p*-Iodo-hydrocinnamic acid. [141°]. White prisms. Formed by reduction of *p*-iodo-cinnamic acid with HI and P (Gabriel a. Herzberg, B. 16, 2040).

β -Iodo-phenyl-propionic acid $C_6H_4I.CH_2.CH_2.CO_2H$. [120°]. Formed by adding fuming HIAq to a concentrated aqueous solution of β -oxy-phenyl-propionic acid (Glaser, A. 147, 97). Formed also from cinnamic acid and conc. HIAq in the cold (Fittig a. Binder, A. 195, 188). Small crystals (from CS₂). Decomposed on fusion. Boiling with water converts it into HI and cinnamic acid. Aqueous Na₂CO₃ gives HI, styrene, and CO₂.

o-IODO-DI-PHENYL-PROPYLIDENE-DIAMINE $C_{12}H_{10}I_2N_2$, *i.e.* $CH_2I.C_6H_4.CH(NHPh)_2$.

Formed by heating β -iodo-propionic aldehyde with excess of aniline (Chautard, A. Ch. [6] 16, 159). Brownish-yellow needles or tables, v. sol. all ordinary solvents. Decomposed by heat without previous fusion. Gives no crystalline salts.

DI-IODO-DI-PHENYL SULPHIDE $C_{12}H_8I_2S$, *i.e.* $(C_6H_4I)_2S$. [189°]. Formed by heating di-phenyl sulphide with iodine and iodic acid in sealed tubes. Got also from di-amido-di-phenyl sulphide by the diazo-reaction (Krafft, B. 7, 1165). Lamine.

p-IODO-PHENYL THIOCARBIMIDE $C_6H_4I.NCS$. [65°]. Formed by the action of iodine on an alcoholic solution of di-*p*-iodo-di-phenyl-thio-urea (Losanitsch, B. 5, 158). Crystals.

DI-p-IODO-DI-PHENYL-THIO-UREA $C_{12}H_{10}I_2S$, *i.e.* $CS(NH.C_6H_4I)_2$. [173°]. From *p*-iodo-aniline, alcohol, and CS₂ (Losanitsch, B. 5, 157). V. sl. sol. alcohol and ether.

IODO-iso-PHTHALIC ACID $C_6H_4I(CO_2H)_2$, [6:3:1]. [204°]. Formed by oxidation of iodo-tolyl methyl ketone $C_6H_4I.MeI.CO.CH_3$ [1:2:5] with CrO₃ (Klingel, B. 18, 2701). Fine white needles. Sublimable. V. sol. alcohol, acetic acid, and ether, insol. cold water.

Salts.—A'Ba: very sparingly soluble fine white needles.—A'Ca: microscopic needles.—A'Ag: white crystalline pp.—A'Cu: green crystalline pp.

IODO-PROPANE v. PROPYL IODIDE.
Di-iodo-propane $C_3H_7I_2$, *i.e.* $CH_3.CH_2I.CH_2I$. *Propylene iodide*. S.G. 1.25 2.49. From propylene and iodine (Berthelot a. De Luca, C. R. 89, 748). From allyl iodide and gaseous HI at –18° (Malbot, C. R. 107, 114; Bl. [2] 50, 449). Liquid. Split up by alcoholic potash into iodine and propylene.

Di-iodo-propane $CH_3I.CH_2I.CH_2I$. *Tri-methyl-ene iodide*. (227°); (169° at 170 mm.). S.G. $\frac{1}{4}$ 2.5681; $\frac{1}{2}$ 2.5962; $\frac{3}{4}$ 2.5614. Obtained by heating *s*-di-oxy-propane (trimethylene glycol) with fuming HIAq at 100° (Freund, M. 2, 640). Also from trimethylene bromide, alcohol, and KI (Perkin, jun., C. J. 51, 12).

Di-iodo-propane $CH_3I.CH_2I.CH_2I$. *Allylene dihydro-di-iodide*. (148°). S.G. 2 2.15 (O.); 2.45 (S.). Obtained by direct combination of allylene with HI (in conc. solution) (Oppenheim, Bl. [2] 4, 434; Semenov, Bl. [2] 5, 446). Heavy oil. Partly decomposed by distillation, but may be distilled with steam or with any indifferent gas. Sl. sol. alcohol, v. sol. ether. Becomes coloured in air and light. Alcoholic potash forms $CH_3.Cl.CH_2I$. Ag₂O gives acetone (Srookin, Z. 1871, 264).

IODO-PROPIOLIC ACID C_6HIO , *i.e.* $I.C_2CO_2H$. *Iodo-propargylic acid*. *Iodo-acetylene carboxylic acid*. [140°]. Small colourless prisms or glassy needles.

Formation.—1. By saponification of the ethyl ether.—2. By the action of a solution of iodine in KI upon the cuprous compound of calcium or barium propargylate.

Reactions.—It combines with HBr to form brom-iodo-acrylic acid [96°]; with HI it yields β -di-iodo-acrylic acid [135°]; with bromine dissolved in chloroform it yields di-bromo-iodo-acrylic acid [147°]; with an ethereal solution of iodine, tri-iodo-acrylic acid [207°]; and with iodine bromide, bromo-di-iodo-acrylic acid [162°].

On the other hand, an aqueous solution of bromine converts it into di-bromo-iodo-ethylene IBrC:CHBr with evolution of CO_2 .

Salts.—A'K: small glistening very hygroscopic needles. A'Ag: white pp., decomposed by waggling with water forming AgI . A'Ba: easily soluble amorphous solid. A'Cu.

Ethyl ether A'Et: [68°]; large colourless prisms. Formed by the action of a solution of iodine in KI upon the cuprous compound of propargylic ether (Baeyer, B. 18, 2274; Homböke & Stolz, B. 18, 3282; 19, 536).

α -IODO-PROPIONIC ACID $\text{C}_3\text{H}_5\text{IO}$, i.e.

$\text{CH}_3\text{CH}(\text{IO})\text{CO}_2\text{H}$. Prepared by digesting syrupy lactic acid (1 mol.) with PI_3 (1 mol.), pouring the product into water and extracting with ether (Wichelhaus, A. 144, 352). Oil, nearly insol. water.

β -Iodo-propionic acid $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$. [82°].

Formation.—1. By the action of iodide of phosphorus on glyceric acid (Beilstein, A. 120, 226; 122, 366; Erlenmeyer, A. 191, 284).—2. From acrylic acid and conc. HIAg (Wislicenus, A. 166, 1).

Preparation.—The product of the oxidation of glycerin with nitric acid is evaporated on the water-bath, and the syrupy residue diluted with water until it possesses S.G. 1.26. This solution (30 c.c.) is then poured into a flask containing iodine of phosphorus prepared from iodine (50 g.) and yellow phosphorus (6.5 g.). After the vigorous action has taken place, the solid residue is recrystallised from water (V. Meyer, B. 19, 3294; 21, 24).

Properties.—Colourless laminæ; v. sol. hot, v. al. sol. cold, water; v. e. sol. alcohol and ether. May be converted into propionic acid by HI or by sodium-amalgam (Moldenhauer, A. 131, 328).

By boiling with water it is converted into hydroacrylic acid and a little acrylic acid. Boiling with water and Ag_2O forms hydroacrylic acid, para-adipic-malic acid $\text{C}_4\text{H}_6\text{O}_5$, dihydroacrylic acid $\text{C}_4\text{H}_6\text{O}_4$, and paracrylic acid $\text{C}_4\text{H}_6\text{O}_3$ (Beilstein; Wislicenus, Z. [2] 4, 683; Socloff; Klimenko, Bl. [2] 34, 321; v. also ACRYLIC ACID).

β -Iodo-propionic acid is converted into adipic acid by heating with reduced silver (W.). AgNO_3 gives in an aqueous solution of β -iodo-propionic acid an immediate pp. of AgI .

Methyl ether MeA. (188°). S.G. 1.841 (Henry, C. R. 100, 114). Colourless oil, turning brown in light. Is not pungent. Formed from the acid, alcohol, and H_2SO_4 .

Ethyl ether EA. (202°) (Fittig & Wolff, A. 216, 128). S.G. 1.707 (Henry). Formed by heating an alcoholic solution of the acid after adding a few drops of H_2SO_4 . Formed also by dissolving the acid (1 pt.) in alcohol (3 pts.) and saturating with HCl , the yield is only 50 p.c. for much EtI is evolved (Lewkowitsch, J. pr. [2] 20, 167; Wichelhaus, B. 1, 25; Wislicenus, A. 192, 129). Oil. Partly decomposed on distillation.

Amide $\text{CH}_3\text{CH}_2\text{CONH}_2$. [101°]. Formed by the action of aqueous NH_3 on the methyl ether in the cold (Henry). Colourless tables, turning yellow in light. V. sol. water. Its solution gives a pp. with AgNO_3 .

β -IODO-PROPIONIC ALDEHYDE $\text{CH}_3\text{CH}_2\text{CHO}$. S.G. 1.221. Prepared by the action of iodine (25 g.) and iodic acid (10 g.) on propionic aldehyde (18 c.c.) diluted with alcohol

(50 c.c.)⁹. It is washed with KOH solution and poured into water (Chauvard, A. Ch. [6] 16, 157).

Properties.—Heavy colourless liquid, not inflammable, with an exceedingly irritating vapour. Miscible with alcohol, ether, and acetone; al. sol. water. Is totally decomposed at 100°. Very dilute solutions of KOH , NaOH , or NH_4HO attack it slowly in the cold. Conc. solutions resinify it. Mineral acids behave similarly. HNO_3 oxidises it to $\text{CH}_3\text{I.CH}_2\text{CO}_2\text{H}$ [82°]. $\text{Ag}(\text{C}_2\text{H}_3\text{O}_2)$ forms propyl acetate (90°). AgCN and silver sulphocyanide give $\text{CH}_3(\text{CN}).\text{CH}_2\text{CO}_2\text{H}$ and $\text{CH}_3(\text{CNS}).\text{CH}_2\text{CO}_2\text{H}$. Aniline gives the compound $\text{CH}_3\text{I.CH}_2\text{CH}(\text{NH}_2\text{C}_6\text{H}_5)$.

α -IODO-PROPYL ALCOHOL v. *Iodhydrin of PROPYLENE GLYCOL*.

Di-iodo-propyl alcohol $\text{C}_3\text{H}_5\text{IO}$ i.e. $\text{CH}_3\text{I.CH}(\text{I}).\text{CH}_2\text{OH}$. *Di-iodide of allyl alcohol*. [45°]. Prepared by dissolving iodine in allyl alcohol (Hübner & Bellmann, B. 13, 460; 14, 207). Colourless needles. Easily decomposed by light or heat. Sol. alcohol, ether, and benzene, insol. water. On heating the chloroform solution it gives a compound crystallising in colourless prisms [160°], which is probably an iodo-allyl alcohol.

Di-iodo-isopropyl alcohol $\text{CH}_3\text{I.CH}(\text{OH}).\text{CH}_2\text{I}$. *Glycerin di-iodhydrin*. [c. 18°]. S.G. 1.24. Prepared by heating the *s*-dichlorhydrin of glycerin with KI and water on a salt-bath (Nahmacher, B. 5, 353; Claus, A. 168, 24). Faintly yellowish oil. Decomposes when distilled.

p -IODO-PROPYL-BENZENE $\text{C}_6\text{H}_4(\text{C}_3\text{H}_7)\text{I}$ [1.4]. [250°]. Formed by heating *p*-diazopropyl-benzene with HI (Louis, B. 16, 110). Volatile with steam. Colourless oil. Sol. ether, m. sol. alcohol, almost insol. water. On oxidation with cold CrO_3 in acetic acid it gives *p*-iodobenzoic acid.

p -Iodo-iso-propyl-benzene $\text{C}_6\text{H}_4(\text{C}_3\text{H}_7)\text{I}$ (234°). Prepared by heating *p*-diazopropyl-benzene with HI (Louis, B. 16, 114). Colourless oil. On oxidation it gives *p*-iodobenzoic acid.

α -IODO-PROPYLENE v. ALLYL IODIDE.

α -Iodo-propylene $\text{CH}_3\text{CH}(\text{I}).\text{CH}_2$. *Allylene hydro-iodide*. (82°) (S.); (93°–103°) (O.). S.G. 1.835; 1.803. Formed by decomposing di-iodo-propane $\text{CH}_3\text{I}_2\text{CH}_2$ (1 mol.) with alcoholic KOH (1 mol.), and mixing the distillate with water (Semenoff, Bl. [2] 5, 446; Z. 1865, 725; Oppenheim, Bl. [2] 4, 484; Z. 1865, 719).

Di-iodo-propylene $\text{C}_3\text{H}_4\text{I}_2$ i.e. $\text{CH}_2\text{CI}:\text{CH}(\text{I})$. *Allylene di-iodide*. (198°). Obtained by exposing allylene for two months to a solution of I in aqueous KI in sunshine (Oppenheim). Oil. Turns brown in light. Yields allylene with alcoholic KOA .

Tri-iodo-propylene $\text{CHI}:\text{CI}:\text{CHI}$. *Di-iodo-allyl iodide*. *Propargyl tri-iodide*. [41°]. Formed by the combination of propargyl iodide with iodine (Henry, B. 17, 1132). Small colourless needles.

Tri-iodo-propylene $\text{CH}_2\text{CI}:\text{CI}:\text{CH}_2$. *Iodo-allylene di-iodide*. [64°]. From silver allylene and iodine in ethereal solution (Liebermann, A. 185, 278). Needles. Decomposes at 78°. V. e. sol. ether, m. sol. alcohol. Alcoholic potash gives iodo-allylene.

IODO-PROPYLENE-GLYCOL v. *Iodhydrin of GLYCERIN*.

iodo-propyl-thiophene $C_6H_4S.C_3H_6I$ *i.e.* $C_6H_4S.C_3H_5.I$. From *n*-propyl-thiophene (Rufei, Z. 90, 1748). Oil, volatile with steam.

Di-iodo-pyrotartaric acid $C_4H_2IO_6$. [185°]. From itaconic acid and HI at 150° (Swarz, Z. 1866, 732). NoJules. Reduced by further treatment with HI to pyrotartaric acid.

Tetra-iodo-pyrrole $C_4H_2I_4.NH$. 'Iodol.' S. 92; S. (90 p.c. alcohol) 6 at 15°; S. (ether) 50. Formed by the action of an ethereal solution of iodine on pyrrole-potassium (Ciamician a. Dennstedt, G. 13, 18; B. 15, 2582), and by the action of iodine on an alkaline solution of pyrrole (Ciamician a. Silber, G. 16, 543; B. 18, 1766). Long yellowish-brown flat prisms or minute yellow needles (from dilute alcohol). Sol. ether, acetic acid, and hot alcohol, nearly insol. cold alcohol, insol. water and aqueous acids. Decomposes at about 140°-150°. Gives a white pp. with $AgNO_3$, instantly blackening; green colouration with $HgCl_2$. Has no basic properties. It is not decomposed by boiling water, but boiling HCl aq. blackens it. It does not dissolve in aqueous KOH , but alcoholic potash dissolves it forming a potassium derivative which is decomposed by acids (even CO_2) but not by water. Zinc-dust and KOH reduce it to pyrrole (Ciamician a. Silber, B. 19, 8027). When heated gently with conc. H_2SO_4 , it gives at first a green, then a dirty violet colouration. Its alcoholic solution gives a red colour with nitric acid (Vulpis). It is employed pharmaceutically as a substitute for iodoform for suppurating sores, fungoid growths, hay fever, &c., having the advantage of possessing no odour, and exerting no poisonous effect upon the system.

iodo-quinoline $C_8H_6I.N$. [63°]. (above 300°). S.G. 1.93. Prepared by heating quinoline with a KI solution of iodine and HIO_3 (La Coste, B. 15, 780). Monoclinic prisms, or long thin needles. Easily volatile with steam.

Salts.— B^+HCl^- aq.: small yellow needles.— $B^+H_2PtCl_6^-$ 2aq.: long orange needles, sl. sol. water.— $B^+H_2Cr_2O_7^-$: sparingly soluble yellow needles or plates.

Methylo-iodide B^+MeI^- : glistening golden plates; sol. hot water, v. sl. sol. cold water and alcohol, insol. ether.

Methylo-chloride B^+MeCl^- aq.: fine yellowish needles or thick yellow prisms, dimorphous (Lehmann, Z. K. 12, 877). v. sol. water.—(B^+MeCl^-), $PtCl_6^-$: fine orange crystals, sl. sol. cold water.

Formed by heating (Py. 8)-chloro-quinoline with HI (Friedländer a. Weinberg, B. 18, 1531). White needles. Sl. sol. water, v. sol. other solvents.— B^+HI^- : long needles.— $B^+H_2Cl_2PtCl_6^-$ aq.: red needles.

Di-iodo-quinoline $C_8H_3I_2.N$. [90° uncor.]. Formed by the action of iodine in CS_2 on quinoline (Claus a. Istel, B. 16, 824). Dull-green metallic needles. Sol. alcohol, ether, and acetic acid.

Di-iodo-quinone $C_6H_2I_2.O_2$. [159°]. Formed by the action of iodic acid on the diacetyl derivative of hydroquinone (Metzler, B. 21, 2555). Yellow needles (from alcohol). If converted by

the action of sulphurous acid into the hydroquinone [142°].

Di-iodo-quinone $C_6H_2I_2.O_2$. [8:5:4:1]. [180°]. From di-iodo-*p*-amido-phenol (*q. v.*), H_2SO_4 , and $K_2Cr_2O_7$ (Seiffert, J. pr. [2] 28, 488). Formed also by oxidising di-iodo-phenol sulphonic acid with CrO_3 (Kehrmann, J. pr. [2] 37, 586). Golden plates (from benzoline). Readily sublimes, almost insol. cold, v. sl. sol. boiling, water. With HCl and $SnCl_4$ it gives di-iodo-hydroquinone [145°]. $FeCl_3$ reconverts this into di-iodo-quinone.

Di-iodo-quinone-chlorimide $C_6H_2I_2.NCl$  [128°]. From $C_6H_2I_2(NH_2)(OH)$, hydric chloride, and bleaching-powder solution (Seiffert, J. pr. [2] 28, 488). With NMe_2 it gives

iodo-resorcin $C_6H_3I(OH)_2$, *i.e.* $C_6H_3I(OH)_2$. [67°]. Formed by agitating an ethereal solution containing resorcin (10 pts.) and iodine (24 pts.) with PbO (110 pts.), distilling off the ether and recrystallising from benzene (Stenhouse, C. N. 26, 279; A. 171, 811). Trimetric prisms, sol. water.

Tri-iodo-resorcin $C_6H_2I_3(OH)_2$. [145°] (M. a. N.); [154°] (C.). Formed, together with a brown substance insoluble in CS_2 , when ICl is added to an aqueous solution of resorcin (Michael, a. Norton, B. 9, 1752). Formed also by adding an aqueous solution of resorcin to a solution of KIO_3 , iodine, and KI (Claassen, B. 11, 1448). Prepared by adding bleaching powder to a dilute alkaline solution of resorcin (1 mol.) and KI (7 mols.), and then acidifying (Degener, J. pr. [2] 20, 324). Needles (from CS_2), sl. sol. hot water, v. sol. alcohol and ether. May be sublimed. Boiling HNO_3 gives tri-nitro-resorcin.

Di-acetyl derivative $C_6H_2I(OAc)_2$. [170°]. Needles, v. sol. alcohol and ether.

iodo-resorcin sulphonic acid $C_6H_2I(OH)(SO_3H)$. From potassium resorcin sulphate and iodine (H. Fischer, M. 2, 840).— KA' 3aq.: minute crystals.

Iodo-resorcin disulphonate $C_6H_2I(OH)(SO_3H)_2$. Formed by digesting potassium resorcin disulphonate (30 g.) with iodine (33 g.) in dilute alcoholic solution at 100° (F.).— KA' : long needles.

iodo-salicylic acid *v.* **iodo-o-oxy-benzoic acid**.

iodo-stearic acid $C_{18}H_{33}IO_2$. From di-oxy-stearic acid and HI (A. Saytzeff, J. pr. [2] 32, 309). Oil.

Iodo-stearic acid $C_{18}H_{33}IO_2$. From oleic acid, PI_3 , and a little water. The product is mixed with water and extracted with ether (M. C. a. A. Saytzeff, J. pr. [2] 35, 884).

Properties.—Oil. Resembles the preceding acid.

Reactions.—1. Reduced by Zn and HCl to stearic acid.—2. Moist Ag_2O forms a substance that is unsaturated (taking up 55 p.c. I from its solution in $HgCl_2$ aq.) but is converted by alcoholic KOH into oxy-stearic acid.—3. Alcoholic KOH forms solid iso-oleic acid [45°], and also ordinary oleic acid.

Iodo-stearic acid $C_{18}H_{33}IO_2$. Formed by heating iso-oleic acid with tri-iodide of phosphorus and water (Coust a. Saytzeff, J. pr. [2] 37, 276; B. [2] 47, 169). Oil, sol. ether.

Reactions.—1. Yields an oxy-stearic acid [85°] on treating with silver oxide.—2. Alcoholic potash regenerates iso-bleic acid [40°–45°], but forms no oleic acid.—3. Alkaline KMnO_4 oxidises it to di-oxy-stearic acid [78°].

IODO-STEARIDENIC ACID $\text{C}_{18}\text{H}_{33}\text{IO}_2$. Iodo-oleic acid. From ricinoleic acid $\text{C}_{18}\text{H}_{33}\text{O}_2$, water, P, and iodine at 100° (Claus, B. 9, 1917). Oil. Reduced by boiling with zinc and HClAq to stearic acid. Combines with bromine.

DI-IODO-SUCCINAMIC ACID
 $\text{CO}_2\text{H} \cdot \text{CH}_2 \cdot \text{CH}(\text{I}) \cdot \text{CONH}_2$.

Ethyl ether A'Et: [134°]; long needles; slightly soluble in cold water. Formed by the action of iodine upon diazo-succinamic ether $\text{CO}_2\text{Et} \cdot \text{CH} \cdot \text{ON}_2 \cdot \text{CONH}_2$ in ethereal solution (Curtius a. Koch, B. 19, 2462; J. pr. [2] 38, 485).

IODO-TARCONINE v. NARCOTINE.

IODO-THIENYL METHYL KETONE

$\text{C}_6\text{SH}_4\text{ICO} \cdot \text{CH}_3$. Iodo-acetothienone. [129°]. Formed by the action of acetyl chloride upon mono- or di-iodo-thiophene in presence of Al_2Cl_6 (Gattermann a. Römer, B. 19, 692). Long colourless needles (from alcohol). Very volatile with steam. Strong odour. By alkaline KMnO_4 it is oxidised to iodo-thiophene carboxylic acid [181°].

Thiophenyl-hydrasine $\text{C}_6\text{SH}_4\text{C}(\text{N} \cdot \text{HPh}) \cdot \text{CH}_3$: [134°]; yellow tables; sl. sol. alcohol.

(a) **IODO-THIOPHENE** $\text{C}_6\text{H}_4\text{IS}$ i.e.

$\text{CH} \cdot \text{CH} \begin{array}{l} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{array} \text{S}$. (182° cor.). Oil. Formed by the action of iodine and HgO on thiophene at the ordinary temperature (Meyer a. Kreis, B. 17, 1558; Egli, B. 18, 544). With sodium and EtI it gives ethyl-thiophene. With Na and *n*-butyl bromide it forms *n*-butyl-thiophene (182°). Gives an iodo-nitro-thiophene [74°] (Kreis, B. 17, 2073).

Di-iodo-thiophene $\text{C}_6\text{H}_2\text{I}_2\text{S}$. [40°]. White crystals. Formed by the action of 2 mols. of iodine and HgO on thiophene at the ordinary temperature (Meyer a. Kreis, B. 17, 1558).

IODO-THIOPHENE CARBOXYLIC ACID $\text{C}_6\text{SH}_4\text{I}(\text{CO}_2\text{H})$. Iodo-thiophenic acid. [131°]. Formed by oxidation of iodo-thiophenyl methyl ketone with alkaline KMnO_4 (Gattermann a. Römer, B. 19, 693). Colourless silky needles (from water). Sublimes in glistening tables.— $\text{NH}_4\text{A}'$: needles, sl. sol. cold water.

(a) **IODO-THIOPHENE-(β)-DI-SULPHONIC ACID** $\text{C}_6\text{H}_2\text{I}(\text{SO}_3\text{H})_2$. Formed by sulphonation of (a)-iodo-thiophene. On reduction with sodium-amalgam it yields thiophene-(β)-di-sulphonic acid (Langer, B. 18, 559).

IODO-THIOXENE is Iodo-DI-METHYL-THIOPHENE (q. v.).

IODO-THYMOL $\text{C}_8\text{H}_7\text{MePr}(\text{OH})\text{I}$ [1:4:3:6]. [69°]. Prepared by adding iodine (8.5 g.) to a solution of thymol (5 g.) in ammonia (8 c.c.) mixed with alcohol (2 c.c.) and distilling the oily product with steam (Willgerodt a. Kornblum, J. pr. [2] 39, 289). Lustrous white needles, insol. water, sol. other solvents. Oxidised by MnO_2 and H_2SO_4 or by FeCl_3 to thymoquinone. Not attacked by aqueous NaOH at 800°. HNO_3 forms nitro-thymol, displacing I by NO_2 . H_2SO_4 forms a sulphonic acid.

Ethyl derivatives $\text{C}_8\text{H}_7\text{MePrI}(\text{OEt})$. [52°]. Opaque white trimetric tables, insol. cold water, sl. sol. hot water and alcohol.

Acetyl derivatives. $\text{C}_8\text{H}_7\text{MePrI}(\text{OAc})$. [71°]. White needles.

Benzoyl derivatives. $\text{C}_8\text{H}_7\text{MePrI}(\text{OBz})$. [95°]. Large tables.

Picryl derivative: [155°]; yellowish crystalline aggregates.

IODO-THYMOL SULPHONIC ACID

$\text{C}_8\text{H}_7\text{MePr}(\text{OH})\text{ISO}_3\text{H}$ [1:4:3:2:6]. From thymol by successive sulphonation and iodination (Kehrmann, J. pr. [2] 39, 392). Gives an iodo-thymoquinone on oxidation. HNO_3 gives di-nitro-thymol [53°].— $\text{KA}'2\text{aq}$: crystals, melting in water of crystallisation at 80°, decomposed at 120°.— BaA' .— AgA' .

IODO-THYMOQUINONE $\text{C}_8\text{H}_6\text{MePrIO}_2$ [5:2:6:4:1]. [61°]. Formed by oxidising iodo-thymol sulphonic acid with CrO_3 (Kehrmann, J. pr. [2] 39, 392). Yellowish-red prisms. Reduces to an iodo-hydrothymoquinone [74°].

Oxim $\text{C}_8\text{H}_6\text{MePrIO}(\text{NOH})$ [5:2:6:4:1]. [130°]. Formed by heating the quinone with hydroxylamine hydrochloride in diluted (75 p.c.) alcoholic solution. Long yellow prisms and needles, sl. alcohol and ether, insol. cold water. Its acetyl derivative $\text{C}_8\text{H}_5\text{MePrIO}(\text{NOAc})$ crystallises in golden needles [70°]. Its sodium derivative crystallises in greenish laminae.

Iodo-thymoquinone $\text{C}_8\text{H}_6\text{MePrIO}_2$ [5:2:3:4:1]. [66°]. From iodo-carvacrol sulphonic acid by oxidation with chromic acid mixture (Kehrmann, J. pr. [2] 40, 188). Garnet-red tables, sl. alcohol and ether. More volatile with steam than its isomeride. Smells like quinone. Hydroxylamine slowly forms an oxim.

o-IODO-TOLUENE $\text{C}_6\text{H}_4\text{I}$ i.e. $\text{C}_6\text{H}_4\text{I} \cdot \text{CH}_3$ [2:1]. (205°) (B. a. K.); (211° i. v.) (K.). S.G. 22 1.697 (B. a. K.). Formed from o-toluidine by the diazo-reaction (Beilstein a. Kuhlberg, Z. 8, 102; A. 158, 347; Kekulé, B. 7, 1007; Mabery a. Robinson, Am. 4, 101). Oil.

Reactions.—1. Oxidised by dilute nitric acid to o-iodo-benzoic acid [157°].—2. With ClCO_2Et and Na it forms $\text{C}_6\text{H}_3\text{I} \cdot \text{Me} \cdot \text{CO}_2\text{Et}$.—3. CrO_3Cl_2 gives $\text{C}_6\text{H}_3\text{I} \cdot \text{CHCl}_2$ and a little $\text{C}_6\text{H}_3\text{I} \cdot \text{CHO}$ (Stuart a. Elliott, C. J. 53, 805).—4. When heated with H_2SO_4 it forms iodo-toluene sulphonic acid, di-iodo-toluene, and tri-iodo-toluene (Neumann, A. 241, 62).

m-Iodo-toluene $\text{C}_6\text{H}_4\text{I} \cdot \text{CH}_3$ [3:1]. (204°). S.G. 22 1.698. From m-toluidine by the diazo-reaction (B. a. K.).

p-Iodo-toluene $\text{C}_6\text{H}_4\text{I} \cdot \text{CH}_3$ [4:1]. [35°]. (211.5°). From p-toluidine by the diazo-reaction (Körner, Bull. Acad. Belg. 1867, 157). The same body appears to be formed from mercury ditolyl and iodine, although the melting-point is given as 20° (Dreher a. Otto, A. 154, 171). Laminae. May be sublimed. Gives p-iodo-benzoic acid when oxidised by chromic acid mixture. H_2SO_4 forms iodo-toluene sulphonic acid and di- and tri-iodo-toluene (Neumann, A. 241, 58).

o-Iodo-toluene v. BENZYL IODIDE.

o-IODO-TOLUENE SULPHONIC ACID $\text{C}_6\text{H}_4\text{ISO}_3\text{H}$ i.e. $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{ISO}_3\text{H}$. From o-iodo-toluene and SO_3 (Mabery a. Palmer, Am. 6, 170). Syrupy liquid.— BaA' , 1½ aq: needles.— CaA' , 2½ aq.— PbA' , 2 aq.

p-Iodo-toluene (α)-sulphonic acid $C_6H_4I.SO_3H$. Formed, together with the (β)-isomeride, by gradually adding p-iodo-toluene to SO_3 , both dissolved in chloroform (Glassner, *B. 8*, 560).— BaA' , 4aq: needles; v. s. sol. water.

p-Iodo-toluene (β)-sulphonic acid $C_6H_4I.SO_3H$. Formed as above. Deliquescent crystalline mass.— KA' aq: very soluble laminae.— NaA' aq: dense aggregates of whetstone-shaped very soluble crystals.— CaA' , 3aq: very soluble silky needles.— BaA' , aq: thin laminae, sl. sol. water.— CuA' , 6aq: light-blue needles, v. sol. water.

• **Amide** $C_6H_4MeI.SO_2NH_2$. [179°]. Crystals; m. sol. hot water, v. sol. alcohol.

Iodo-toluene disulphonic acid

$C_6H_3MeI_2(SO_3H)_2$, [1:4:3:2].

From $C_6H_3Me(NH_2)(SO_3H)_2$ by diazo-reaction (E. Richter, *A. 230*, 325; Limpricht, *B. 18*, 2179). Slender white needles; v. sol. alcohol and water.— BaA' , 6aq: prisms, v. sol. water.— K_2A' , 2aq: small prisms.

Chloride $C_6H_3MeI_2(SO_2Cl)_2$, [143°]. After one fusion it melts at 126°. Long white prisms; sl. sol. ether.

Amide, [130°–132°]. White needles (from water).

IODO-p-TOLUIDINE $C_6H_4MeI(NH_2)$, [1:4:2]. [49°]. (273°). From iodo-o-nitro-toluidine by reduction (Heynemann, *Z. 12*, 6, 402; *A. 158*, 338). Needles. Boils, with rapid decomposition, at 273°. V. s. sol. alcohol, ether, and CS_2 .— $B'HNO_3$: colourless nacreous laminae. S. 95 at 16°.

Iodo-toluidine $C_6H_4MeI(NH_2)$, [1:4:3]. [189°]. From p-iodo-toluene by nitration and reduction (Glassner, *B. 8*, 561). Needles or plates; v. sol. alcohol.— $B'HCl$: needles.— $B'HNO_3$: plates.— $B'HSO_3$: needles.

Di-iodo-p-toluidine $C_6H_3MeI_2(NH_2)$, [1:3:5:4]. [124°–5°]. Formed by the action of ICl on p-toluidine dissolved in $HClAq$ (Michael a. Norton, *B. 11*, 115; *Am. 1*, 263). Ramified groups of slender needles; m. sol. cold alcohol, sl. sol. hot water.

IODO-TOLUIDINE SULPHONIC ACID

$C_6H_3Me(NH_2)I(SO_3H)$, [1:2:4:5]. From the diazo-derivative of $C_6H_3Me(NO_2)(NH_2)(SO_3H)$, [1:2:4:5] and conc. HCl at 140° (Limpricht a. Foth, *A. 230*, 308; *B. 18*, 2185). Satiny needles (containing aq). Sl. sol. cold water, m. sol. hot water.— BaA' : trimetric tables; v. sol. water.

IODO-TOLUQUINONE C_6H_3MeIO , [6:2:4:1]. [117°]. Formed by oxidising a solution of iodo-toluenesulphonic acid in sulphuric acid with chromic acid (Kehrmann, *J. pr. 2*, 37, 340; 39, 392). Long reddish-yellow needles; m. sol. ether. Reduced by stannous chloride to iodo-hydroxytoluquinone [111°]. With hydroxylamine it gives the mono-oxim crystallising in short yellow prisms [156°].

Di-iodo-toluquinone $C_6H_2MeIO_2$, [3:6:2:4:1]. [118°]. From di-iodo-m-cresol* sulphonic acid and CrO_3 (Kehrmann, *J. pr. 2*, 39, 392). Garnet-red laminae; v. sol. organic solvents. May be sublimed.

DI-IODO-DITOLYL, [8:4:1] $C_8H_6MeI_2C_6H_4MeI$, [1:3:4]. [100°]. From di-amido-ditolyl by Sandmeyer's modification of the diazo-reaction (Stolle, *B. 21*, 1096). Yellow needles.

• **IODO-DI-TOLYL-ETHYLIDENE-DI-AMINE** $CH_3CH(OH)(NH_2)C_6H_4Me$. Obtained by

heating iodo-acetic aldehyde with p-toluidine (Chautard, *A. Ch. 6*, 16, 156). Orange-yellow prisms or tables; decomposed by heat. Does not furnish crystalline salts.

IODO-TOLYL METHYL KETONE

$C_6H_4MeI.CO.CH_3$, [1:2:5]. [39°]. Formed by heating diazo-tolyl methyl ketone (from amido-tolyl methyl ketone [102°]) with an excess of HI (Klingel, *B. 18*, 2700). Yellowish prisms. V. sol. alcohol and ether; sl. sol. ligroin and benzene; insol. water. By CrO_3 it is oxidised to iodo-iso-phthalic acid [204°].

β-IODO-VALERIC ACID

$C_6H_4I.CO_2H$, i.e. $(CH_3)_2CH.CH_2.CO_2H$. [80°]. Solidifies at 53°. Separates as crystals when HI is passed into a concentrated solution of β-oxy-isovaleric acid (Schirokoff, *J. pr. 2*, 23, 286). Converted by sodium-amalgam to isovaleric acid.

Iodo-valeric acid $C_6H_4I.CO_2H$ (?). **Hydro-iodide of tiglic acid**. [86°–5°]. Formed by the combination of tiglic (methyl-crotonic) acid with HI which may be effected in the cold (Schmidt a. Berendes, *A. 191*, 117). Formed also, together with the following, when angelic acid is heated with $HIAq$ (Schmidt, *A. 208*, 254). Needles; sl. sol. cold water; decomposed by boiling with water. Converted by zinc and dilute H_2SO_4 into $C_6H_4MeH.CO_2H$. Aqueous $AgNO_3$ gives AgI , tiglic acid and CO_2 .

Iodo-valeric acid $CH_3.CHI.CHMe.CO_2H$. [46°]. **Hydro-iodide of angelic acid**. From angelic acid and conc. $HIAq$ in the cold (Fittig, *A. 216*, 162). Prisms, v. sol. water. Zinc and dilute H_2SO_4 converts it into $C_6H_4MeH.CO_2H$. Aqueous $AgNO_3$ gives AgI , tiglic acid, and CO_2 . Aqueous Na_2CO_3 at 0° gives CO_2 , ψ-butylene $CH_3.CH:CH.CH_3$, and HI . V. also **Angelico acid**, vol. i. p. 266.

IODO-ISOVALERIC-ALDEHYDE $C_6H_4I.O$ i.e. $(CH_3)_2CH.CHI.CHO$ (?). S.G. at 2–17.

Preparation.—Isovaleric aldehyde (24 c.c.) dissolved in alcohol (50 c.c.) is treated with iodine (20 g.) and iodic acid (8 g.). The reaction takes place at the ordinary temperature, and is complete in about 15 days. The liquid is poured into excess of water, and decolourised by alkali or reduced silves (Chautard, *A. Ch. 6*, 16, 160).

Properties.—Colourless liquid, blackening on exposure to light, and having an extremely irritating and suffocating odour. It is completely decomposed at 100°, and is not solidified at –20°. V. sol. alcohol and ether, less sol. benzene, $CHCl_3$, and CS_2 . Sl. sol. water.

Reactions.—Rapidly decomposed by alkalis. The action of ammonia is complex, giving valeric aldehyde-ammonia, valeridine $C_6H_4I.N$, and valeritrine $C_6H_4I.N$. Forms a crystalline compound with $NaHSO_4$. $Ag(C_6H_4I.O)$ at 100° yields amyl acetate (138°). $AgCN$ and $AgSCN$ react forming AgI and the corresponding derivatives. Forms a mono- and a di-anilide with aniline.

IODO-VANILLIN v. Methyl derivatives of

IODO-DI-OXY-BENZOIC ALDEHYDE

DI-IODO-VINYL-AMINE $CH_2=CH.NH_2$, [192° with decomposition]. Formed by the action of cold aqueous NH_3 , CO_2 , and alcohol being eliminated upon the di-iodo-oxy-acrylic ether $Cl_2C(OH).CO_2Et$, obtained by treating diazo-oxy-acrylic ether $ON_2C(OH).CO_2Et$ with an ethereal solution of iodine (Buchner a. Curtius, *B. 19*, 851). Small yellowish prisms. Very

sparsely soluble in cold water and ether, more easily in hot water and hot alcohol. Volatile with steam. It is stable towards acids, but alkalis act free NH_3 in the cold.

DI-*o*-iodo-*o*-xylene $\text{C}_8\text{H}_6(\text{CH}_3)_2$, *o*-Xylylene-iodide. [110°]. Prismatic crystals. Formed by heating phthalyl alcohol (di-*o*-oxy-xylene) with HI (Leser, B. 17, 1826).

Di-*o*-iodo-*p*-xylene $\text{C}_8\text{H}_6(\text{CH}_3)_2$, [c. 170°]. Obtained by boiling [4:1] $\text{C}_8\text{H}_6(\text{CH}_3)_2$, with conc. HIAg for a few minutes (Grimaux, Z. 1870, 895). Slender needles, sl. sol. ether, v. sol. boiling alcohol and chloroform. Turns yellow in air. Not very volatile with steam.

iodoplumbic acid H_2PbI_4 , v. LEAD, iodide of, *Combinations*, No. 3.

IONS. The elements or radicals into which a compound is primarily separated by electrolysis (v. PHYSICAL METHODS, section *Electrical methods*).

IPPECUANIC ACID $\text{C}_{11}\text{H}_{15}\text{O}_7$. An acid existing, according to Willigk (A. 76, 342), along with emetine (q. v.) in the root of *Cephalis Ipecacuanha*. It is extracted by boiling alcohol, ppd. by basic lead acetate, and the pp. decomposed by H_2S . Reddish-brown, very bitter, amorphous mass, m. sol. ether, v. sol. alcohol and water. Colours ferric salts green, the colour being changed to violet by ammonia. Its dilute solution does not ppt. $\text{Pb}(\text{OAc})_2$, but ppts. basic lead acetate. Its alkaline solution absorbs oxygen from the air. It thus somewhat resembles gallic acid. Podwysotzky (Ph. [3] 10, 642) by extracting ipecacuanha with ether and light petroleum obtained an acid ('Erythrocephalein'), which formed a purple-red alkaline salt, and which crystallised from chloroform in coloured needles.

IPOMIC ACID $\text{C}_8\text{H}_9\text{O}_6$. [104°]. Produced by the action of nitric acid on jalapin (Mayer, A. 83, 143; Poleck a. Samelson, C. C. 1884, 813). Resembles sebacic acid.

IRIDIUM. In At. w. 192.5. Mol. w. unknown. [2200°] (Van der Weyde); [1950°] (Violle, C. R. 89, 702); [2500°] (Pictet, C. R. 88, 1817). S.G. 22.42 at 17.5° (Deville a. Debray, P. M. [4] 50, 651). $\text{S.H.}^\circ 0^\circ\text{--}100^\circ = -0.323$, $0^\circ\text{--}1400^\circ = -0.401$ (Violle, C. R. 89, 702). C.E. linear .000007 (Fizeau, A. R. 68, 1125).

Occurrence.—As metal, alloyed with Pt, Os, Ru, Rh, and Pd. Specimens of platinum-iridium, osmium-iridium, &c., contain from 25 to 78 p.c. Ir (v. Deville a. Debray, A. Ch. [3] 56, 431; Berzelius, P. 13, 435, 527; 15, 209). In 1802 Tennant (T. 1804, 411) noticed a metallic residue when he dissolved Pt ore in *aqua regia*; this residue was examined by Desobry (Gehlen's Journ. Chem. 2, 273), and Fourcroy a. Vauquelin (Gehlen's Journ. Chem. 3, 362). In 1804 Tennant (l.c.) showed that the residue contained two new metals; to one he gave the name *Iridium* because of the varied colours of its oxides, and to the other the name *Osmium* because of the peculiar smell of its volatile oxide.

Formation.—1. By digesting Ir_2O_3 or IrCl_3 with formic acid.—2. By action of sunlight on an alcoholic solution of Ir-sulphate.

Preparation.—When Pt ore is heated with *aqua regia* osmium and platinum-iridium remain as black insoluble scales. Ir is prepared from the residue by various methods. 1. W. von

Schneider (A. Suppl. 3, 261) mixes the insoluble in *aqua regia* with NaCl , and heats it to redness in a stream of Cl; Os is thus removed. The residual mixed chlorides are titrated with the smallest possible quantity of water, and then washed on to a filter; the solution is treated with Cl, mixed with a little HClAg , and shaken up with excess of KCl; the pp. is washed with water, and then with saturated KClAg . The pp. is now nearly pure K_2MCl_6 , M = Ir, Ru, and Pt. The pp. is dissolved in much boiling water, and H is passed in for several days (the flask being closed by a caoutchouc cork) until the supernatant olive-green liquid treated with potash becomes colourless and then blue or turbid. Pt and Ru are thus wholly ppd. as metals, and most of the Ir remains in solution as IrCl_4 . H is removed by a stream of CO_2 —otherwise explosions occur on opening the flask from the action of the ppd. Pt and Ru on the H and O in the flask—the cork is removed, and the liquid is again saturated with H; Ir is ppd. on the surface of the liquid in large lustrous laminae.—2. Matthéy (Pr. 28, 463) prepares Ir free from all metals except Pt as follows. Ordinary Ir, finely divided, is fused with 10 times its weight of Pb; the Pb is dissolved in HNO_3Ag , and the insoluble is digested for a long time with *aqua regia*; the insoluble is fused with KHSO_4 (to remove Rh), and then melted with 10 times its weight of KOH and 3 times its weight of KNO_3 in a gold crucible; the cold mass is treated with cold water, in which K iridate remains insoluble. The insoluble is well washed with water containing a little KOH and NaClO , and then with water; fairly conc. cold NaClOAg is added to the residual blue solid; after a time the water is distilled off; the residue is again fused with KNO_3 and KOH, and treatment with dilute NaClOAg and KOHAg is repeated. The blue solid is now dissolved in *aqua regia*, the liquid is evaporated to dryness, and the residue is redissolved and filtered; the dark-coloured liquid is slowly poured into conc. NaOHAg containing NaClO , and Cl is passed in, the liquid being kept in a distilling apparatus; the blue oxide of Ir thus obtained is collected, washed, dried, and reduced in a mixture of CO and C_2H_2 (made by gently warming oxalic acid with sulphuric acid). Metallic Ir is thus obtained, while any Fe present remains as oxide. The mass is heated to redness with KHSO_4 , and repeatedly washed with ClAg to remove Au, and with HFAg to remove SnO_2 ; it is finally washed with water and dried. Pt may be removed by dissolving in *aqua regia*, saturating with NH_4Cl , dissolving the double NH_4Ir and NH_4Pt chlorides in hot water, reducing by SO_2 when $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is formed, and dissolves with olive-green colour, while $\text{PtCl}_2 \cdot 2\text{NH}_4\text{Cl}$ remains insoluble; the reduction should be stopped before the whole of the $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is reduced (the presence of a little of this salt gives a deep-red colour to the mixed chlorides). The solution is oxidised by HNO_3 , NH_4Cl added, and the ppd. $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ is washed with NH_4ClAg , and strongly heated, when Ir remains as a grey metallic powder (Claus, J. pr. 42, 251). Wöhler a. Mucké (A. 104, 306) reduce the mixed Pt-NH₄ and Ir-NH₄ chlorides by digesting with slightly warm KONaAg till the undissolved is light yellow-brown, taking care to avoid excess; $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is formed and

dissolves, while $\text{PtCl}_2 \cdot 2\text{NH}_4\text{Cl}$ remains unreduced and insoluble. For other methods of preparing Ir v. Deville a. Debray (*A. Ch.* [3] 56, 431); Claus (*C. C.* 1862, 129); Wöhler (*P.* 31, 161; 104, 368; 107, 857); Fremy (*A. Ch.* [3] 44, 885); Martius (*A.* 107, 860); Bunsen (*A.* 446, 274).

Properties.—As prepared by heating $\text{IrCl}_2 \cdot 2\text{NH}_4\text{Cl}$, Ir forms a grey spongy mass; Ir as a grey powder is produced by heating $\text{IrCl}_2 \cdot 2\text{KCl}$ with excess of Na_2CO_3 , washing and reducing in H; by heating to whiteness and compressing, a compact lustrous mass is obtained. When fused in a very powerful O-H flame, Ir forms a white, lustrous mass resembling polished steel; brittle when cold, somewhat malleable at red heat (D. a. D.). Harder than iron. S.G. of porous Ir varies from 16 to 19. Ir which has been very strongly heated is insoluble in all acids; Ir black is sol. in *agua regia*. Heated in Cl, Ir black forms IrCl_3 .

The atomic wt. of Ir has been determined by heating $\text{IrCl}_2 \cdot 2\text{KCl}$ in H (Berzelius, *P.* 13, 435, 527; 15, 208); by reducing $\text{IrCl}_2 \cdot 2\text{NH}_4\text{Cl}$ in H and weighing the residual Ir, and by reducing the double Ir-K chloride in H and dissolving out the KCl (Seubert, *B.* 11, 1767). As no compound of Ir has been gasified, the valency of the atom of Ir in gaseous molecules is not determined. From the crystalline form of osm-iridium G. Rose (*P.* 77, 143) concluded that Os and Ir are isomorphous, and that both belong to the hexagonal system.

In its chemical reactions, Ir is closely related to Os and Pt, and less closely but very distinctly related to Ru, Rh, and Pd; all these elements are metallic, but the instability of their salts, the solubility of the hydrated oxides MO_3 in alkalis, and the formation of acids H_2MCl_4 and H_2MBr_4 , show the non-metallic tendencies of the Pt metals (v. NOBLE METALS).

Ir is used alloyed with Pt for making instruments, &c., which remain unchanged in air, e.g. for making the normal metre preserved as the standard of reference. Stylographic pens are sometimes tipped with Ir. When Ir powder is heated to whiteness with $\frac{1}{2}$ its weight of B, the whole melts; on cooling, the mass may be readily worked by strongly heating with lime, the P is entirely removed.

Reactions and Combinations.—1. Heated in oxygen, compact Ir is not oxidised; Ir black is oxidised to Ir_2O_3 , which decomposes again at c. 1000° (Deville a. Debray, *C. R.* 1878, 441; cf. DISSOCIATION, vol. ii. p. 397).—2. Ir black is oxidised by fusion with nitre, potash, potassium carbonate, or potassium-hydrogen-sulphate.—3. Heated in chlorine IrCl_3 is formed; mixed with NaCl or KCl, and heated in Cl, soluble $\text{IrCl}_2 \cdot 2\text{Na(K)Cl}$ is formed.—4. Heated in an alcohol flame, Ir becomes covered with a blackish layer which disappears on heating in air, leaving a portion of the Ir combined with C (v. Iridium carbide).—5. Ir probably combines with phosphorus when the elements are heated together; when the product is heated in air, Ir and a phosphate of Ir are formed.

Iridium alloys.—Faraday a. Stodart (*A. Ch.* 21, 73); Deville a. Debray (*C. R.* 61, 839); Fiesau (*C. R.* 78, 1205); Morin (*C. R.* 78, 1502); Wöhler (*A.* 146, 275).

Osmium-iridium alloy. Occurs in South

America, California, Australia, Ural Mountains, &c. Hexagonal prisms; lustrous, steel-grey. Slightly malleable; S.G. 19.3 to 21.1. Analyses show composition approximating to formulae Ir_2Os , IrOs and IrOs_2 , with Ir more or less replaced by Pt, Rh, and Ru; but it is probably non-homogeneous (D. a. D.). Heated in air, OsO_4 is given off; heated with KNO_3 and KOH K osmate and iridate are formed. Scarcely acted on by *agua regia*. Alloys with Fe (F.).

Platinum-iridium alloy. Occurs native in octahedra. 1 pt. Ir heated in O-H flame with 10 pts. Pt gives a ductile alloy; Pt alloyed with 15–20 p.c. Ir is insoluble in *agua regia*. For accounts of the Pt-Ir alloy used for making the normal standard metre v. D. a. D. and also M. Alloys of Ir with Pt and Rh, and with Pt, Rh, and Sn were prepared by D. a. D. Alloys of Ir with Cu, Au, Pb, Hg, Ru, and Sn have been prepared.

Iridium, ammonio-salts of, or Irid-ammonium salts. (*Ammoniacal iridium bases*.) IrCl_3 dissolves in $(\text{NH}_4)_2\text{CO}_3$ aq. aid on neutralising with HCl aq. the compound $\text{IrCl}_2 \cdot 2\text{NH}_3$ is produced; treated with H_2SO_4 aq. this compound yields $\text{IrSO}_4 \cdot 2\text{NH}_3$. $\text{IrCl}_2 \cdot 2\text{NH}_3$ dissolves in boiling NH_4Aq , and the compound $\text{IrCl}_2 \cdot 4\text{NH}_3$ forms on cooling; this compound gives a sulphate and nitrate, SO_4 and 2NO_3 , replacing Cl_2 . From $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is obtained $\text{IrCl}_4 \cdot 5\text{NH}_3$, and this again yields a basic hydroxide $\text{Ir(OH)}_3 \cdot 3\text{NH}_3$, a carbonate $\text{Ir}_2(\text{CO}_3)_4 \cdot 10\text{NH}_3$, and other salts. Finally by treating $\text{IrCl}_2 \cdot 2\text{NH}_3$ with conc. HNO_3 aq. the compound $\text{IrCl}_2(\text{NO}_3)_2 \cdot 4\text{NH}_3$ is obtained; AgNO_3 aq. does not ppt. Cl from this salt; treated with HCl aq. the salt $\text{IrCl}_2 \cdot \text{Cl}_2 \cdot 4\text{NH}_3$ is produced from which AgNO_3 aq. ppts. only half the Cl. The foregoing compounds may be formulated as double salts of IrCl_2 , IrCl_3 , IrCl_4 , &c., with NH_3 ; but many of their reactions are better explained if we regard them as salts of condensed ammoniums containing Ir. The following classification is that usually adopted:

1. IRIDAMMONIUM COMPOUNDS: $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{X}_3$, and $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{X}_4$; or $\text{NH}_4(\text{NH}_4)_2\text{Ir}_2\text{X}_3$, and $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Ir}_2\text{X}_4$, &c., obtained from IrCl_3 .

Iridosammonium chloride $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{Cl}_2$ (simplest formula $\text{IrCl}_2 \cdot 2\text{NH}_3$ = di-ammonio-iridium dichloride). A yellow, curdy pp., obtained by dissolving IrCl_3 in excess of $(\text{NH}_4)_2\text{CO}_3$ aq. and neutralising the greenish-yellow liquid with HCl aq. Insol. hot and cold water. Heated gives NH_4Cl , HCl and Ir (Skoblikoff, *A.* 84, 275). Heated with H_2SO_4 aq. easily soluble orange-coloured iridosammonium sulphate, $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{SO}_4$, is produced.

Iridoso-diammonium chloride $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{Cl}_3$ or $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Ir}_2\text{Cl}_3$ (simplest formula $\text{IrCl}_3 \cdot 4\text{NH}_3$ = tetrammonio-iridium dichloride). $\text{IrCl}_3 \cdot 2\text{NH}_3$ is boiled with NH_4Aq until almost all dissolved, the solution is filtered and allowed to cool. Nearly white pp., insol. in cold water; heated, or placed in boiling water, goes to $\text{IrCl}_2 \cdot 2\text{NH}_3$ (Skoblikoff, *loc. cit.*). The sulphate, $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{SO}_4$, is obtained by the action of H_2SO_4 aq. on the chloride; and the nitrate, $\text{N}_2\text{H}_5 \cdot \text{Ir}_2(\text{NO}_3)_4$, by addition of Ba_2NO_3 aq. to a solution of the sulphate in warm water.

2. IRIDO-AMMONIUM COMPOUNDS $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{X}_4$, or $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Ir}_2\text{X}_4$; obtained from IrCl_4 .

Irido-pentammonium chloride $\text{N}_2\text{H}_5 \cdot \text{Ir}_2\text{Cl}_5$ (simplest formula $\text{IrCl}_4 \cdot 10\text{NH}_3$ = decammonio-

iridium trichloride). $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$ is dissolved in water, an equal volume of conc. NH_4Aq is added, a flask is quite filled with the liquid, and allowed to stand for several weeks in a warm place until the olive-green colour of the liquid has changed to deep rose-red; after gentle warming, to remove excess of NH_3 , the liquid is saturated with HClAq and evaporated to dryness; the greenish-yellow salt which separates during evaporation is washed with cold water, and then crystallised from water acidified with HCl . Flesh-coloured, crystalline, powder; v. sl. sol. water (Claus, *J. pr.* 63, 99; *A.* 98, 317).

Irido-pentammonium hydroxide $\text{N}_5\text{H}_{10}\text{Ir}_2(\text{OH})_6$. Known only in solution which is obtained by digesting the chloride with moist Ag_2O . Solution is alkaline; neutralised by acids gives carbonate, nitrate, and sulphate.

8. IRIDI-AMMONIUM COMPOUNDS $\text{N}_5\text{H}_{12}\text{IrCl}_3 \cdot \text{X}^1_3$ or $\text{N}_5\text{H}_9(\text{NH}_4)_3\text{Cl}_3 \cdot \text{Ir}_2 \cdot \text{X}^1_3$; obtained from series I by oxidation.

Iridi-diammonium chloride? better *chlor-iridi-diammonium chloride* $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot \text{Cl}_3$ (simplest formula $\text{IrCl}_3 \cdot 4\text{NH}_3$ = *tetrammonio-iridium tetrachloride*). Obtained by slowly warming iridosammonium chloride ($\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3$) with conc. HNO_3Aq , dissolving the salt which separates in hot water, adding excess of HClAq , and crystallising from hot water. Violet octahedra; AgNO_3Aq ppts. only $\frac{1}{2}$ the Cl from this salt. The salt which separates after treating $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3$ with HNO_3 is the *nitrate*, $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot (\text{NO}_3)_3$; AgNO_3Aq does not ppt. Cl from this salt. When this salt is evaporated with dilute $\text{H}_2\text{SO}_4\text{Aq}$, the *sulphate*, $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot \text{SO}_4$, is obtained (Skoblikoff, *L.c.*). Palmær (*B.* 22, 15) describes $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot \text{Cl}_3$, $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot (\text{NO}_3)_3$, $\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3 \cdot \text{Cl}_3$, and $(\text{N}_5\text{H}_9\text{Ir}_2\text{Cl}_3) \cdot \text{SO}_4 \cdot 2\text{H}_2\text{O}$.

References.—For other memoirs besides those referred to, v. Weltzien, *A.* 97, 19; Gibbs a. Gent, *J.* 1858, 244; Birnbaum, *B.* 13, 1544.

Iridium boride of. When Ir is heated with B to a very high temperature a fusible mass is obtained; no definite boride has been isolated (Wöhler a. Deville, *A. Ch.* [2] 52, 71).

Iridium bromides of (Birnbaum, *A.* 133, 161). Only one bromide has been isolated, $\text{IrBr}_3 \cdot 4\text{H}_2\text{O}$; there are indications of the existence in solution of a tetrabromide, IrBr_4 . Ir does not combine directly with Br; nor is it soluble in a mixture of HNO_3 and HBrAq .

IRIDIUM TRIBROMIDE $\text{IrBr}_3 \cdot 4\text{H}_2\text{O}$ (*Irido-bromide*, *iridium sesquibromide*). When the blue hydrate $\text{IrO}_3 \cdot \text{H}_2\text{O}$ (obtained by heating a solution of IrCl_3 with alkali) is dissolved in HBrAq and evaporated *in vacuo*, olive-green six-sided crystals separate, and then steel-blue needles. The olive-green crystals are $\text{IrBr}_3 \cdot 4\text{H}_2\text{O}$, and the steel-blue crystals are $\text{IrBr}_3 \cdot 3\text{HBr} \cdot 3\text{H}_2\text{O}$. The bromide loses $3\text{H}_2\text{O}$ at $100^\circ\text{--}120^\circ$; it is sol. water, insol. alcohol or ether; aqueous solution is green, but becomes blue probably with formation of IrBr_4 .

Irido-bromhydric acid $\text{IrBr}_3 \cdot 3\text{HBr} \cdot 3\text{H}_2\text{O} (= \text{H}_3\text{IrBr}_6 \cdot 3\text{H}_2\text{O})$. Crystallises in steel-blue crystals which melt at 100° , giving off $3\text{H}_2\text{O}$; deliquescent; easily sol. water, alcohol, ether; oxidised by HNO_3 , probably to IrBr_4 .

Ammonium-iridium tribromide, or *Ammonium iridobromide* or *bromiridite*

$2(\text{IrBr}_3 \cdot 3\text{NH}_4\text{Br}) \cdot 3\text{H}_2\text{O}$, is obtained by reducing $\text{IrBr}_3 \cdot 2\text{NH}_4\text{Br}$ (formed by adding $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ to hot NaBrAq and cooling) by SO_2 , and neutralising by $(\text{NH}_4)_2\text{CO}_3$. The following other double salts are described by Birnbaum (*A.* 133, 161): $\text{IrBr}_3 \cdot 3\text{HBr} \cdot \text{IrBr}_3 \cdot 3\text{AgBr}$, $\text{IrBr}_3 \cdot 3\text{KBr} \cdot 3\text{H}_2\text{O}$, $\text{IrBr}_3 \cdot 3\text{NaBr} \cdot 12\text{H}_2\text{O}$.

IRIDIUM TETRABROMIDE (Iridobromide). When $\text{IrO}_3 \cdot \text{H}_2\text{O}$ is dissolved in HBrAq , or when $\text{IrBr}_3 \cdot 2\text{KBr}$ is decomposed by $\text{K}_2\text{SiF}_6\text{Aq}$, a solution is obtained which loses Br on evaporation, and on addition of HNO_3Aq , after evaporation, gives a deliquescent, blue, crystalline mass, easily sol. in water and alcohol. The blue solution probably contains $\text{IrBr}_3 \cdot 2\text{HBr}$ (Birnbaum). This solution does not yield double compounds with other metallic bromides.

Ammonium-iridium tetrabromide, or *Ammonium iridobromide* or *bromiridate* $\text{IrBr}_3 \cdot 2\text{NH}_4\text{Br} \cdot (\text{NH}_4)_3\text{IrBr}_3$. Dark-blue octahedra; by adding $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ to hot NaBrAq , and cooling.

Potassium bromiridate $\text{IrBr}_3 \cdot 2\text{KBr} \cdot (\text{K}_2\text{IrBr}_6)$. When solution of IrCl_3 , or $\text{IrCl}_3 \cdot 2\text{NaCl}$, or $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ is warmed with conc. KBrAq , a greenish-blue liquid is obtained from which very dark-blue crystals of K_2IrBr_6 separate; the salt is recrystallised from hot water.

Sodium bromiridate also exists.

Iridium carbide of (IrC_2). When a coherent mass of Ir is held in the flame of a spirit-lamp, black masses appear on the surface; these burn when heated in air and leave 80.2 p.c. Ir (Berzelius, *P.* 15, 213).

Iridium chlorides of. Three chlorides are known: IrCl_3 , IrCl_4 , and IrCl_5 ; as none has been gasified the formulae are not necessarily molecular (v. *Iridium, haloid compounds* of). When Ir black is heated in Cl, IrCl_3 is formed; when Cl is passed over a heated mixture of Ir black and KCl, $\text{IrCl}_3 \cdot 2\text{KCl}$ is produced.

IRIDIUM DICHLORIDE (Iridosochloride). IrCl_2 . A blackish-green, isosoluble, solid. By passing Cl over Ir black heated to low redness (Berzelius, *P.* 13, 470). The change is not complete, as the temperatures of formation and decomposition are nearly the same (Claus, *A.* 59, 849). By heating Ir sulphite in Cl (Fellenberg, *P.* 50, 66). By carefully heating IrCl_3 (Skoblikoff, *A.* 84, 275). Seubert (*B.* 11, 1761) describes an acid $\text{IrCl}_2 \cdot \text{H}_2\text{SO}_4 \cdot 4\text{NH}_4\text{Cl}$ from which salts of NH_4 and Na are obtained.

IRIDIUM TRICHLORIDE (Iridochloride). *Iridium sesquichloride*. IrCl_3 . Olive-green solid, insol. in acids or alkalis (Claus, *A.* 107, 129). Obtained by heating Ir black in Cl, also by strongly heating an alkali double salt of IrCl_3 with conc. H_2SO_4 , and pouring into cold water (Berzelius, *P.* 13, 470). A soluble hydrate $\text{IrCl}_3 \cdot 4\text{H}_2\text{O}$ is obtained by dissolving $\text{IrO}_3 \cdot \text{H}_2\text{O}$ in HClAq , reducing by H_2S , and evaporating.

Double salts. Ammonium-iridium trichloride (Ammonium chloriridite) $2(\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}) \cdot 3\text{H}_2\text{O}$; formed by slowly evaporating mixed solutions of $\text{IrCl}_3 \cdot 3\text{NaCl}$ and NH_4Cl , or by reducing $\text{IrCl}_3 \cdot 2\text{NH}_4\text{ClAq}$ by H_2S , adding conc. NH_4ClAq , filtering if necessary, and slowly evaporating (Claus, *J. pr.* 42, 351; Seubert, *B.* 11, 1761); olive-green, rhombic plates.

Potassium chloriridate $\text{IrCl}_3 \cdot 3\text{KCl} \cdot 3\text{H}_2\text{O}$. By reducing $\text{IrCl}_3 \cdot 2\text{KCl}$ in H_2S and evaporating with addition of KCl . Olive-green efflorescent prisms. The following double salts are also known:— $2\text{IrCl}_3 \cdot (12\text{NH}_4)_2\text{CO}_3\text{Cl}_2$; $\text{IrCl}_3 \cdot 3\text{HgCl}$; $\text{IrCl}_3 \cdot 3\text{AgCl}$; $\text{IrCl}_3 \cdot 3\text{NaCl} \cdot 12\text{H}_2\text{O}$ (Claus, l.c.; Karnfrod a. Uhrlaub, A. 81, 120).

IRIDIUM TETRACHLORIDE (Iridichloride). IrCl_4 . The solution obtained by decomposing $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ suspended in water by Cl contains IrCl_4 (Vauquelin, A. Ch. 89, 150, 225); a solution of IrCl_4 is also obtained by dissolving IrO_3 in HClAq , digesting IrCl_3Aq with *aqua regia*, or decomposing $\text{IrCl}_3 \cdot 2\text{KCl}$ with $\text{H}_2\text{SiF}_6\text{Aq}$ (Berzelius, P. 13, 470). By evaporating these solutions to dryness at temperatures not above 40° , IrCl_4 is obtained as a black mass, translucent with dark-red colour at the edges; very deliquescent; decomposed by heat to IrCl_3 and Cl , and then to Ir ; combines with alkali chlorides to form double salts. **Ammonium-iridium tetrachloride (Ammonium chloriridate)** $\text{IrCl}_4 \cdot 2\text{NH}_4\text{Cl}$; obtained by mixing conc. solutions of NH_4Cl and IrCl_3 , or $\text{IrCl}_3 \cdot 2\text{NaCl}$. Crystallises from hot water in dark red-brown octahedra, isomorphous with $\text{PtCl}_4 \cdot 2\text{NH}_4\text{Cl}$. S. 5 in cold water. Reduced by SO_2 to the more soluble $\text{IrCl}_3 \cdot 3\text{NH}_4\text{Cl}$.

Potassium chloriridate $\text{IrCl}_3 \cdot 2\text{KCl}$. Formed by mixing conc. solutions of its constituent salts; also by dissolving IrO_3 in HClAq (solution probably contains H_2IrCl_6) and adding KCl ; also by passing Cl at a gentle heat over an intimate mixture of Ir black and KCl , dissolving in hot water, filtering from Ir , evaporating to dryness with addition of *aqua regia*, dissolving out KCl by small quantities of cold water, dissolving in hot water, adding a little *aqua regia*, and evaporating to the crystallising point. Black octahedra; very sl. sol. cold water, much more sol. hot water, insol. alcohol. Heated, goes to $\text{IrCl}_3 \cdot 3\text{KCl}$, and at higher temperature to Ir and KCl .

The following chloriridates have also been obtained:— $\text{IrCl}_3 \cdot 2(\text{NH}_4)_2\text{CH}_3\text{Cl}$ (Vincent, J. R. 100, 112); $\text{IrCl}_3 \cdot 2\text{NaCl} \cdot 6\text{H}_2\text{O}$ (Vauquelin, l.c.; Berzelius, l.c.).

Iridium, cyanides of, also Iridicyanides, v. vol. ii. p. 332.

Iridium, haloid compounds of. The only haloid compound certainly formed by direct union of the elements is IrCl_3 . When an intimate mixture of Ir black and KCl is heated in Cl_2 or of Ir black and KI is heated in I_2 , the double salt K_2IrCl_6 or K_2IrI_6 is obtained. The following formulæ present the composition of the haloid compounds and the double salts, which they form with alkali haloid compounds:—

double alkali-iridium haloid salts are probably better regarded as salts of the acids H_2IrX_6 , H_2IrX_4 , and H_2IrX_2 . The chloriridates (salts of H_2IrCl_6) are readily reduced to chloriridides (salts of H_2IrCl_4).

Iridium, hydroxides of, v. Iridium, oxides and hydrated oxides of.

Iridium, iodides of (Oppler, Ueber Iodverbindungen des Iridiums [Göttingen, 1857]; J. 1857, 263). Two iodides, IrI_3 and IrI_4 , have been isolated. There are indications of the existence of IrI_2 . Ir and I do not directly combine.

IRIDIUM DI-IOXIDE (Iridoso-iodide). The brown solid obtained by leading SO_2 into IrI_3 suspended in water is perhaps IrI_2 . When a solution of $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in boiling KIAq is allowed to cool, a black crystalline powder separates; this is **ammonium iridium di-iodide**, $\text{IrI}_2 \cdot 2\text{NH}_4\text{I}$.

IRIDIUM TRI-IOXIDE (Irido-iodide. Iridium sesqui-iodide) IrI_3 . A black crystalline pp.; by adding NH_4Cl to $\text{IrI}_3 \cdot 2\text{KIAq}$. Very slightly sol. cold water, more sol. hot water.

Double salts.—**Ammonium-iridium tri-iodide (Ammonium iodiridate)** $2(\text{IrI}_3 \cdot 3\text{NH}_4\text{I}) \cdot \text{H}_2\text{O}$. Crystalline needles; by dissolving $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in boiling KIAq , cooling, filtering from $\text{IrI}_3 \cdot 2\text{NH}_4\text{I}$, concentrating, and recrystallising from hot water.

Potassium iodiridate, $\text{IrI}_3 \cdot 3\text{KI}$. Green lustrous crystalline powder; by reducing IrCl_3 by H_2S with addition of KIAq . **Silver iodiridate**, $\text{AgI} \cdot 3\text{KI}$, has also been obtained.

IRIDIUM TETRA-IOXIDE (Iridio-iodide) IrO_4 . A black powder; by boiling IrCl_3Aq with KI in presence of a little HCl .

Double salts.—**Ammonium-iridium tetra-iodide (Ammonium iodiridate)** $\text{IrI}_4 \cdot 2\text{NH}_4\text{I}$. Separates after some weeks from solution of $\text{IrCl}_3 \cdot 2\text{NH}_4\text{Cl}$ in cold conc. KIAq ; dark-brown lustrous crystals, easily decomposed by heat; aqueous solution gently heated deposits IrI_3 and $\text{IrI}_2 \cdot 2\text{NH}_4\text{I}$. **Potassium iodiridate**, K_2IrI_6 . Separates, after IrI_3 , from a solution of IrCl_3 in KIAq . Also formed by dissolving IrI_3 in KIAq , and allowing to crystallise; also, in small quantity, by action of I vapour on an intimate mixture of Ir black and KI at 60° – 70° . **Sodium iodiridate**, $\text{IrI}_4 \cdot 2\text{NaI}$, has also been obtained.

Iridium, oxides and hydrated oxides of. The only oxides of Ir which have been certainly isolated are Ir_2O_3 and IrO_2 . The former forms a hydrate with $3\text{H}_2\text{O}$, and another hydrate probably with $5\text{H}_2\text{O}$. IrO_2 forms the hydrate $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$. Hydrated IrO_2 dissolves in alkalis probably with formation of *iridates*; $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$

None of the Ir haloid compounds has been gasified. The formulæ are given from the analogies between these compounds and those of other Pt metals. The only binary compounds of Pt metals which have been gasified are OsO_2 and RuO_2 . The acid H_2IrBr_6 has been obtained. The

dissolves in some acids, but no salts have thus been prepared. Alkaline *iridates* appear to exist. There are indications of the existence of an oxide with less O than Ir_2O_3 , probably IrO . When Ir black is heated in O , Ir_2O_3 is formed; the oxide decomposes again at c. 1000° . IrO_2 is the most

IRIDIUM, OXIDES OF:

stable oxide; $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ rapidly absorbs O from the air, and passes into $\text{IrO}_2 \cdot x\text{H}_2\text{O}$.

Lamrous oxide (*Iridium monoxide*). IrO . When IrCl_3 is boiled with KOHAq a black powder separates; this is probably IrO (Berzelius, P. 13, 479). Claus (A. 59, 249) thinks that this oxide is obtained by heating one of the double salts of IrSO_3 with K_2CO_3 in a stream of CO_2 . On adding KClAq to $\text{IrCl}_3 \cdot 3\text{NaClAq}$, and filtering, a solution of IrCl_3 is obtained; when $\text{K}_2\text{CO}_3\text{Aq}$ is added to this liquid (or to $\text{IrCl}_3 \cdot 3\text{KClAq}$) a greyish-green pp. is formed, which is probably a hydrate of IrO ; the pp. is sol. in excess of $\text{K}_2\text{CO}_3\text{Aq}$ (Berzelius, l.c.). A few salts derived from IrO are known, e.g. $\text{IrSO}_3 \cdot 4\text{H}_2\text{O}$; they are not, however, formed directly from the oxide, but by reducing $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ or chloriridates by SO_2 .

IRIDIC OXIDE AND HYDRATE (*Iridium dioxide*) IrO_2 and $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$. By adding excess of alkali to IrCl_3Aq and heating, a heavy indigo-blue pp. $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$ is produced. The same compound is obtained by using IrCl_3Aq in place of IrCl_3 , and allowing the pp. to stand in the air, when it absorbs O. The pp. is soluble in dilute $\text{H}_2\text{SO}_4\text{Aq}$ or HNO_3Aq . When the hydrate is heated in a stream of CO_2 , IrO_2 remains as a black powder quite insoluble in acids (Claus, A. 59, 249). No salts corresponding with IrO have been prepared. By adding CaOAq to a solution of IrO_2H_2 in HClAq a blue pp. is obtained, which is a compound of IrO_2 with CaO . When Ir black is fused for some time with KNO_3 , and the blackish-green mass is treated with water, part dissolves, forming a deep indigo-blue solution, and part remains as a black crystalline powder. The quantity of K in this powder is variable, but the ratio of $\text{Ir}:\text{O}$ is always 1:3 (Claus, A. 59, 249). The powder is probably an iridate of K, $\text{IrO}_2 \cdot x\text{K}_2\text{O}$.

IRIDO-IRIDIC OXIDE AND HYDRATES (*Iridium sesquioxide*) Ir_2O_3 and $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$. The oxide Ir_2O_3 is obtained by heating $\text{IrCl}_3 \cdot 2\text{KCl}$ with 2 parts K_2CO_3 or Na_2CO_3 in a stream of CO_2 , washing the fused mass with boiling water, and then with water containing NH_4Cl , heating to remove NH_4Cl , treating with acid to remove alkali, and again washing with water (Claus, A. 59, 249). A hard blue-black powder; decomposed by heating to c. 1000° into Ir and O (Deville & Debray, C. R. 1878. 441; cf. Dissociation, vol. ii. p. 397). Reduced to Ir by H at the ordinary temperature. The hydrate $\text{Ir}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ($= \text{IrO}_2\text{H}_2$) is obtained by adding to $\text{IrCl}_3 \cdot 2\text{NaClAq}$ so much KOHAq that all remains dissolved, and then heating or ppg. by alcohol. Black pp. insol. in acids except conc. HClAq , which dissolves it very slightly. By adding a little KOHAq to solution of an alkaline chloriridate, and quite filling a flask with the liquid, a yellow-green pp. forms, which is probably $\text{Ir}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$; it oxidises very easily to the blue $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$; easily soluble in the slightest excess of alkali. De Boisbaudran (C. R. 93, 1236, 1406, 1551) describes a violet-coloured pp. which is probably $\text{Ir}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, obtained by adding alkali to $\text{Ir}_2(\text{SO}_4)_3 \cdot 3\text{K}_2\text{SO}_4\text{Aq}$ (this salt is formed by heating Ir compounds with KHSO_4 , and treating the product with $\text{K}_2\text{SO}_4\text{Aq}$). A few salts, and some double and basic salts, corresponding with Ir_2O_3 are known; they are pro-

duced indirectly. The sulphites and double sulphites are produced by reducing $\text{Ir}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ or chloriridates by SO_2 . By adding CaOAq to IrCl_3Aq a yellow pp. of $\text{Ir}_2\text{O}_3 \cdot 8\text{CaO}$ is produced (Claus, A. 59, 249). Compounds of Ir_2O_3 with NO , and with nitrites, are described by Gibbs (B. 4, 280).

Iridium, oxychloride of. An oxychloride of Ir is said by Berzelius (P. 13, 484) to be formed as a yellowish-brown pp. by adding a small quantity of HgNO_3Aq to $\text{IrCl}_3 \cdot 2\text{KClAq}$; HgCl_2 goes into solution; addition of more HgNO_3 causes ppn. of HgCl .

Iridium, phosphide of. When Ir is very strongly heated with $\frac{1}{2}$ its weight of P, the whole melts. By heating the product with CaO the P is removed. Ir and P probably combine when heated together, but no phosphide of Ir has been isolated.

Iridium, salts of. Very few salts of Ir are known other than the haloid compounds. Iridous sulphite, $\text{IrSO}_3 \cdot 4\text{H}_2\text{O}$, and some double sulphites, irido-iridic sulphite, $\text{Ir}_2(\text{SO}_3)_3 \cdot 6\text{H}_2\text{O}$, and several double and basic sulphites, and a few other salts (chiefly double and basic), corresponding with Ir_2O_3 , have been isolated. None of these salts is obtained from the corresponding oxide; the sulphites, which are the best-known salts, are formed by reducing $\text{IrO}_2 \cdot 2\text{H}_2\text{O}$, or chloriridates, by SO_2Aq .

Iridium, sulphides of. Three sulphides of Ir are known, IrS , Ir_2S_3 , and IrS_2 . Ir combines with S when heated with it.

IRIDOUS SULPHIDE IrS . (*Iridium monosulphide*.) A blue-black solid; by heating Ir_2S_3 or IrS_2 (Berzelius, P. 13, 487; Böttger, J. pr. 3, 227). The pp. obtained by passing H_2S into a solution of an iridous compound is probably IrS . Does not decompose by heating in absence of air; roasted in air gives SO_2 and a basic sulphate. The pp. dissolves in KHSO_4Aq .

IRIDIC SULPHIDE Ir_2S_3 . (*Iridium disulphide*.) A black powder; obtained by strongly heating Ir black with S and Na_2CO_3 , and washing with water (Fellenberg, P. 50, 60). Heated in air gives SO_2 and Ir . Berzelius (l.c.) obtained a dark brownish-yellow pp. by passing H_2S into IrCl_3Aq ; heated, this gave IrS .

IRIDO-IRIDIC SULPHIDE Ir_2S_5 . (*Iridium sesquisulphide*.) A brown-black pp. by passing H_2S into solution of an irido-iridic compound. Heated gives SO_2 and S, and leaves IrS (Berzelius, l.c.).

M. M. P. M.

IRIDOLINE $\text{C}_{10}\text{H}_8\text{N}_2$. (952° , 257°). S.G. 1.072. A base occurring in coal-tar oil (G. Williams, Tr. 21, 377; C. J. 13, 375).

• **IRIDOSMIUM** & *Iridium*, Alloys of, p. 47.

• **IRIS CAMPHOR** $\text{C}_8\text{H}_8\text{O}_2$. Occurs in the root of *Iris florentina* (Dumas, A. 15, 159). Pearly plates; volatile with steam. Insol. water. Flückiger (Ar. Ph. [3] 8, 481), by distilling iris root with steam, obtained crystals of myristic acid saturated with a fragrant oil.

IRISH PEARL MOSS & *CARAGHAN MOSS*.

IRISIN $\text{C}_8\text{H}_8\text{O}_2$, aq. $[\alpha]_D = -51^\circ$. A carbohydrate extracted from the rhizomes of the water lily (*Iris pseudacorus*) with water and then ppg. with lead acetate. Probably identical with graminin (Wallach, A. 234, 864; B. 21, 896).

Properties.—More strongly laxative than inulin.—F. Does not reduce Fehling's soln.

... is very easily converted into sugar (chiefly levulose) by weak acids. Gives no colouration with iodine. V. sol. strong HI solution from which solution NaOH separates iodoform. Also sol. HCl, and NaOH. Irisin is nearly 4 times as soluble as inulin in water at 22°. Under the microscope the globules of irisin resemble those of inulin, but do not exhibit double refraction.

IRON. Fe. At. w. 55.9. Mol. weight unknown. [1550°] (Pouillet); [1587°] (Daniell, Tr. 1880); [1600°] (Pictet, P. M. 1879. 446). S.G. determinations vary from 6.95 (Roberts a. Wrightson, A. Ch. [5] 30, 274) to c. 8.2. Almost pure Fe has S.G. c. 7.85 at 16° according to Caron (C. R. 70, 1263); 8.189 according to Chandler-Roberts (C. N. 81, 137). S.H. -111641 at 0°; -112359 at 50°; -113795 at 100° (Byström, Oefvers. k. Vetensk. Föreläsning, [Stockholm, 1860] 17, 307; v. also Weinhold, P. 149, 254). C.F. -00001233 at 18° to 100° (Kopp, A. 61, 1; v. also Fizeau, A. Ch. [4] 2, 143; C. R. 68, 1125). T.C. (Ag=100) 11.9 (Wiedemann a. Franz, P. 89, 497). E.C. (Hg at 0°=1) 9.68 at 0°, 6.19 at 100° (Lorenz, W. 13, 422, 582). Crystallises in regular system (Fuchs, A. 84, 257). Emission-spectrum is very complex (Angström, P. 94, 141; Cornu, Spectre Normal [Paris, 1881]; Långström a. Dewar, Pr. 29, 402; 32, 402). Some of the thermal data for Fe are presented in the following table (Th. 3, 293):—

X [Fe, X², Aq]
Cl = 99,950
Br = 78,070
I = 47,650

[Fe, Cl², Aq] = 127,720; [Fe², O², 3H²O] = 191,150;
[Fe², O², H², 3H²SO², Aq] = 35,840;

[Fe, H², SO², Aq] = 24,840.

For further details regarding physical properties v. Rammelsberg's *Hand. der Kryst.-physikal. Chemie*, 1, 193. For the physical properties of different kinds of pig-iron, wrought-iron, and steel, v. DICTIONARY OF APPLIED CHEMISTRY.

Occurrence.—The metal itself is found in small quantities in rocks of volcanic origin and in lavas; it also occurs in meteorites. Compounds of iron are very widely distributed, and occur in immense quantities. The spectroscopic shows the existence of iron (or iron compounds) in the sun and other stars. The chief ores of iron are hematite, Fe₂O₃; brown iron ore, Fe₂O₃.H₂O; yellow ochre, Fe₂O₃.2H₂O; magnetic iron ore, Fe₃O₄; spathic ore, FeCO₃; pyrites, FeS₂ (the formulas express approximately the compositions of the ores).

Preparation.—Commercial iron, whether pig-iron, malleable iron, or steel, always contains more or less C and Si, and generally small quantities of P and S; sometimes also traces of Mn, Ti, Ni, Co, Cu, Sb, and As. 1. Wöhler (A. 94, 125; 95, 192) prepares Fe₃O₄ by heating FeSO₄ crystals with 2-8 parts NaCl in a crucible and washing with water, and reduces the Fe₃O₄ by heating in H (cf. G. de Claubry, C. C. 1859. 214; Luca, C. R. 1851. 332; 1852. 202). Moissan (C. R. 89, 176) says the reduction must be carried out at c. 700°.—2. By reducing FeCl₃ in a stream of H (Peligot, C. R. 19, 870); or in neutral solution at b.-point by Zn (Capitaine, C. R. 9, 767); or by Zn vapour at a high temperature (Poumard, C. R. 39, 518).—3. Troost melts

pig-iron in a lime-crucible by the O-H flame (Bl. [2] 9, 250).—4. A mixture of dry Na₂SO₄ and FeSO₄ is heated in a Pt crucible so long as SO₂ comes off, the residue is washed with cold water, and the crystalline Fe₂O₃ is reduced in H in a Pt crucible, and the Fe is melted in the O-H flame (Matthiessen a. Prus-Szczepanowski, C. N. 20, 501).—5. By electrolysis FeSO₄ aq saturated with NH₄Cl; Fe appears at the negative pole (a large iron plate); it contains H and other gases, which may be removed by heating (Varrentrap, D. P. J. 187, 152; Lenz, J. pr. 108, 438).

Properties.—A lustrous, greyish-white metal. Crystallises in regular cubes or octahedra. Annealed wrought iron wire is extremely tenacious. Such mechanical treatment as hammering, bending, or torsion changes many of the physical properties of iron. The physical properties which have been determined are for the most part those of iron containing small quantities of foreign substances. Iron is magnetic (cf. Faraday, P. 70, 24; Gore, P. M. [4] 40, 170). Pure, or almost pure, Fe is softer and more malleable, but less tenacious, than ordinary malleable iron. The iron obtained by reducing Fe₂O₃ in H at temperatures below c. 600° is pyrophoric; the powder obtained at c. 700° is non-pyrophoric (Moissan, C. R. 89, 176). By passing a weak electric current through FeSO₄ aq mixed with MgSO₄, Lens (C. C. 1870. 188) obtained a greyish, non-crystalline, very brittle mass, easily pulverised by the finger; this iron contained c. 200 times its volume of gases, chiefly H (v. Iron, hydrides of), mixed with CO, CO₂, N, and H₂O vapour; by heating in vacuo the gases were removed, and the iron then resembled Pt in appearance. Iron is unchanged in dry O, but in moist O or in ordinary air it is slowly oxidised to Fe₂O₃.xH₂O; heated in air or O a mixture of Fe₂O₃ and Fe₃O₄ is produced. Iron combines directly with the halogens, also with S, C, B, Si, P, As; it forms alloys with many metals. Iron dissolves in the common mineral acids with formation of salts. Finely divided Fe decomposes water at 100°.

The atomic weight of Fe has been determined (1) by analysing and determining V.D. of FeCl₃ and FeCl₂; (2) by determining S.H. of Fe; (3) by reducing Fe₂O₃ in H (Berzelius, P. 8, 185; Svanberg a. Norlin, A. 50, 432; Erdmann a. Marchand, J. pr. 33, 5; Rivet, A. Ch. [3] 86, 192); (4) by transforming Fe into Fe₂O₃ (B. A. 50, 432; S. a. N., L. c.; Maumené, A. Ch. [8] 80, 880); (5) by determining the Cl in FeCl₃ and in FeCl₂ (Dumas, A. Ch. [9] 55, 157). The atom of Fe is trivalent in the gaseous molecule FeCl₃, and divalent in the gaseous molecule FeCl₂ (v. Iron, chlorides of).

Iron is distinctly a metallic element; it replaces the H of most acids, forming two series of salts, the simplest formulae for which are FeX₂ and FeX₃ respectively, X=Cl, NO₂, SO₄, PO₄, &c. The ferrous salts, FeX₂, are easily oxidised to ferric salts, FeX₃; very many salts, both normal and basic, of both series have been isolated; numerous double salts are also known. Fe₂O₃ forms compounds with several oxides more basic than itself, e.g. with K₂O, BaO, CaO, MgO; these compounds may be

regarded as *ferrites* derived from the hydroxide $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$ ($=\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$). There are also some salts known as *ferrates*, e.g. K_2FeO_4 and BaFeO_4 , which may be looked on as derived from the hypothetical *ferric acid* H_2FeO_4 , but neither this acid nor its anhydride, Fe_2O_3 , has been isolated (v. *FERRATES and FERRITES*, vol. ii. pp. 546-7). Fe_2S_3 , like Fe_2O_3 , forms some double compounds with more basic sulphides; these double compounds may be regarded as *thioferrites* (v. *Iron, sulphides* of). Fe is closely related to Co and Ni; these three metals show some marked analogies with the Pt metals; Fe is also related to Cr and Mn, and it shows some resemblance to Al and the other earth-metals (v. *IRON GROUP OF ELEMENTS*, also *NOBLE METALS*; and cf. *CHROMIUM GROUP OF ELEMENTS*, and *EARTHS, METALS OF THE*).

Reactions and Combinations.—1. Heated in air or oxygen Fe is oxidised to Fe_2O_3 and Fe_3O_4 . 2. Unchanged in dry air at ordinary temperature, but rusts in moist air to $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$.—3. Finely-divided Fe decomposes water at 100° (v. Ramann, B. 14, 1433), and rapidly decomposes steam. Compact Fe decomposes steam at red-heat; Fe_2O_3 is produced. Iron slowly rusts in contact with water and ordinary air; the formation of $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ proceeds slowly at first, and then more rapidly, probably because the Fe and Fe_2O_3 exert an electrolytic action on the water; presence of ammoniacal salts increases the rate of rusting; alkalis and alkaline carbonates hinder the rusting. According to Calvert (C. N. 23, 98) Fe does not rust in water if CO_2 is absent. For an account of the retarding or hastening action of various salts on the rusting of Fe v. Wagner, D. P. J. 218, 70. Various processes have been used for preventing iron-rusting; covering the iron with Zn is frequently done; Barff & Bower heat the iron to c. 650° in water-vapour, whereby a hard protecting film of Fe_3O_4 is formed on the surface of the iron.—4. Fe decomposes solution of hydrogen peroxide, forming $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$; the Fe becomes covered with bubbles of O (Weltzien, A. 138, 129).—5. Iron dissolves in dilute sulphuric or hydrochloric acid with evolution of H . Cold conc. sulphuric acid is almost without action on Fe; when heated, SO_2 is evolved, and $\text{Fe}_2(\text{SO}_4)_3$ formed. Dilute nitric acid dissolves Fe, forming $\text{Fe}(\text{NO}_3)_2$ and NH_4NO_3 , with evolution of N oxides. Conc. nitric acid is almost without action on Fe; v. *infra*, *Passivity of iron*.—6. Heated repeatedly with caustic soda solution Fe forms crystals of $\text{Fe}_2\text{O}_3\cdot\text{H}_2\text{O}$ (Brunck & Graebe, B. 13, 725).—7. When Fe is heated to redness in a stream of ammonia a nitride of Fe is formed, Fe_3N_2 , according to Stahl Schmidt (P. 125, 87).—8. Fe heated in a closed tube with solution of sulphur dioxide to 300° forms solution of FeSO_4 and FeS_2O_8 , and crystals of FeS_2 (Geitner, A. 120, 350).—9. Fe is oxidised to Fe_2O_3 , or K_2FeO_4 (v. vol. ii. p. 547) by fusion with potassium nitrate.—10. Fe combines with the halogens, with arsenic, boron, carbon, hydrogen, nitrogen, phosphorus, and sulphur (v. *Iron, chlorides of, borides of, carbides of, &c.*); it also forms alloys with several metals (v. *Iron, alloys of*).

Passivity of iron. Iron is not acted on by conc. nitric acid; iron which has been immersed in conc. nitric acid does not dissolve in dilute

nitric acid, nor does it ppt. Cu from CuSO_4Aq ; such Fe is said to be *passive*. Co and Ni, and perhaps Bi, also show passivity. According to Varenne (A. Ch. [5] 19, 251; 20, 240) immersion of iron in acid of 100 p.c. HNO_3 is not accompanied by evolution of any gas; if the acid has S.G. 1.382 (c. 63 p.c. HNO_3) NO is evolved copiously for 3 to 20 seconds and then ceases; in both cases the Fe becomes passive. Acid of less S.G. than 1.299 (c. 47 p.c. HNO_3) does not produce passivity. If part of a rod of Fe is dipped into conc. acid, and then the whole is carefully immersed in a dilute acid, the whole rod is passive. These facts are explained by Varenne by supposing that a gaseous film is deposited on the surface of the iron, and protects the iron from the action of the acid; the gas dissolves in the more dilute acid; in the case of the partly-immersed rod the gas-bubbles are removed from one part and then adhere to the other part of the rod. This view was also upheld by Mousson (P. 39, 330), but was controverted by Faraday and Schönbein (P. 39, 342), and Beetz (P. 67, 286, 365). Ramann (B. 14, 1430) considers the passivity to be due to a layer of Fe_2O_3 , which is soluble in dilute, but insoluble in conc. nitric acid. R. thinks that immersion in the acid produces $\text{Fe}(\text{NO}_3)_2$, and that this then reacts with the Fe to produce Fe_2O_3 and NH_4NO_3 ; iron-wire, according to R., becomes passive when partly heated, also by making it the positive electrode in an O -containing liquid. Various oxidising agents acting on Fe render it passive, e.g. HClO_4 , CrO_3 , H_2O_2 (Keir). The passivity of Fe is removed by strongly rubbing the iron, or heating it in reducing gases, also by bringing it into contact with Zn. According to Saint-Edme (C. R. 106, 1079) commercial sheet Ni is passive in ordinary HNO_3Aq ; Fe in contact with Ni becomes passive in the acid; passive Ni remains passive when heated to bright redness in H , whereas Fe loses its passivity.

Detection and Estimation.—Fe compounds are detected by giving a reddish-green colour to the hot borax bead in the oxidising flame, which becomes bottle-green to nearly colourless when cold; also by the ppn. of brown-red $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ by alkalis from ferric compounds; $\text{K}_2\text{FeCy}_4\text{Aq}$ gives a deep blue pp. with ferrous salts, and no pp. but a brownish colour with ferric salts. Fe is estimated, gravimetrically, by ppn. as $\text{Fe}_2\text{O}_3\cdot x\text{H}_2\text{O}$ and weighing as Fe_2O_3 ; volumetrically, by titration with KMnO_4Aq or $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$. For details and for other methods v. *MANUAL OF ANALYSIS*.

Metallurgy of iron. Pure iron is too soft and has too little tenacity for use in making machinery, &c. Ordinary iron is divided into three kinds: pig or cast iron containing from 2 to 5.75 p.c. C, besides small quantities of Si, P, S, and traces of metals other than Fe (chiefly As, Ti, V, Cr, Mn, Cu); malleable or wrought iron containing less than .5 p.c. C; and steel containing about 1 p.c. C. Pig iron is obtained by very strongly heating Fe ores with lime and coal in large furnaces, and blowing in air at the bottom of the furnaces; the C of the coal is burnt chiefly to CO ; and this reacting with oxides of Fe produces Fe, which then combines with, or it may be only dissolves, carbon; the C seems to be produced by a reaction between the partly reduced Fe_2O_3

and CO (v. Bell, *C. J.* [2] 203). • The reduction of Fe_2O_3 is probably aided by cyanides present in the furnace. The greater part of the foreign matter of the iron ores is removed in the form of a fusible slag consisting of silicate of Fe, Ca, Mg, Al, Mn, &c. Wrought iron is obtained by puddling cast iron; in this process the cast iron is strongly heated along with lumps of Fe_2O_3 in a reverberatory furnace; the Fe_2O_3 is partially deoxidised, and the O is used in burning the C, Si, S, and P, the C being thus almost entirely removed as CO or CO_2 . Steel is obtained by completely removing the C from wrought iron by blowing in air, and then adding a sufficient quantity of Fe containing a known quantity of C. Steel is also sometimes made by causing wrought iron to take up C by strongly heating the iron with charcoal. Cast iron is more fusible, harder, and more brittle than wrought iron, which is more ductile and malleable than cast iron. Steel combines the malleability and ductility of wrought iron with the fusibility of cast iron; it is also very hard and elastic. Cast iron is divided into two kinds: *grey cast iron*; granular, with low malleability, S.G. c. 7.1, melting at c. 1600° ; this variety contains C partly in combination with Fe and partly uncombined as graphite; *white cast iron*, harder but not so strong as grey, S.G. c. 7.5, melts at a lower temperature than grey; this variety contains only combined C. By melting grey, and cooling rapidly, white, cast iron is obtained; by melting white, and cooling slowly, grey, cast iron is produced. For details of the metallurgy of iron v. DICTIONARY OF APPLIED CHEMISTRY.

Iron, alloys of. Iron alloys with many metals; the softer metals—Ag, Sn, Zn, &c.—become harder and more tenacious when alloyed with a few parts of iron per thousand; the alloys may generally be prepared by fusing the various metals with iron-wire, a little Fe_2O_3 being added to remove C from the iron.

Alloys with *aluminium* have been described; approximately Al:Fe (Wolfer, A. 115, 102), approximately Al:Fe, and Al:Fe (Calvert a. Johnson, *J.* 1855, 326). Sonnenschein (*J. pr.* 66, 168) described an alloy with lead having a composition approximating to Pb_2Fe . An *amalgam* of iron is formed by mixing finely-divided Fe with Na amalgam, adding a little water, and squeezing out excess of Hg; the crystals correspond in composition to Hg_2Fe_2 ; they slowly undergo decomposition, rapidly when much compressed (Ramann, *B. M.* 1333). Alloys with the following metals have been described:—Sb; Cu (Musket, *P. M.* [8] 6, 81); Mn (*M. J. c.*); Mo (Heine, *J. pr.* 9, 176; Stromeyer, *P.* 28, 55); Wiggins, *P.* 28, 555; Steinberg, *J. pr.* 18, 379); Ni; Pd (Faraday a. Stodart, *Tr.* 1822, 254); Pt (Schönbein, *P.* 42, 17; Boussingault, *A. Ch.* [2] 53, 441); K (Calvert, *P. M.* 1855); Rh (F. a. S., l.c.); Sn (Lassaigne, *J. Chim. med.* 8, 609); Ti (Riley, *C. J.* 16, 387); W (Bernoulli, *P.* 21, 573); Zn (Percy, *Metallurgy*, 2, 153).

Iron, arsenides of. The minerals *arsenical pyrites* and *spieckel* are compounds of Fe with As and with As and S respectively; their compositions approximate to the formulae FeAs_2 and FeAsS . Brittle masses are obtained by fusing together As and Fe out of contact with air, but they have not been much examined.

Iron, borides of. When Fe is heated in a stream of BOI vapour, a hard, white substance is obtained, which is decomposed by boiling water forming H_2BO_3 (? and Fe_2O_3), and evolving H (Freymy, Wurtz's *Dict. de chim.* 1, 1417); by heating ferric borate in H, Lassaigne (*J. Chim. med.* 3, 535) obtained a similar compound; no analyses are given.

Iron, bromides of. Two exist, FeBr_2 and FeBr_3 ; both are produced by the direct union of their elements. Neither has been gasified; the formulae are given because of the analogies between these salts and FeCl_2 and FeCl_3 (v. *Iron, chlorides of*).

Ferrous bromide. (*Protobromide of iron.*) FeBr_2 . A yellow solid; obtained by heating excess of Fe in Br vapour; soluble in water; solution deposits crystals $\text{FeBr}_2 \cdot 6\text{H}_2\text{O}$; decomposed by heating in air to FeBr_3 and Fe_2O_3 (Scheufelen, *A.* 231, 156). Thomsen gives $[\text{Fe}, \text{Br}, \text{Ag}] = 78,070$ (*Th.* 3, 294).

Ferric bromide. (*Sesquibromide of iron.*) FeBr_3 . Dark-red crystals; obtained by heating Fe in excess of Br vapour; may be sublimed, with partial decomposition, out of contact with air; deliquescent. Aqueous solution very easily partially reduced by heating to FeBr_2 (L. de Koninck, *Zeit. anorgan. Chemie*, 1889, 149).

Iron, carbides of. Whether pig-iron is a carbide of iron, or a mixture of carbides and free C, cannot yet be regarded as finally settled. The presence of a few per cents. of C in iron very much modifies the properties of the whole, by making it more fusible; if from 0.2 to 1.5 p.c. C is present, the mass is only fusible with difficulty, but is very hard and tough, it has the properties of wrought iron or steel, according to the quantity of C. Iron takes up C directly, and by so doing has its properties changed. On the temperatures at which carburisation of Fe occurs with amorphous C, diamond, and graphite, v. Hempel, *B.* 18, 998.

The following carbides of Fe have been described, but the investigation of none of these bodies is complete:—(1) Fe_3C , a brittle, fusible mass, by melting together an intimate mixture of equal parts of Fe and C (Faraday a. Stodart, *G. A.* 66, 183); (2) FeC_2 , a black pyrophoric powder, by heating H^+FeCy_3 , or $(\text{NH}_4)_2\text{FeCy}_4$, out of contact with air (Berzelius), or by fusing K_2FeCy_4 , and washing away the KCN produced (Rammelsberg); (3) FeC , was obtained by Karsten by the action of dilute acids on grey pig-iron (*S.* 68, 182); (4) FeC , by the action of Br or I on pig-iron (Berthier, *J.* 1862, 127).

Iron, chlorides of. Two chlorides of iron, FeCl_2 and FeCl_3 , have been isolated; and a third, Fe_2Cl_4 , perhaps exists. When Fe is heated in a stream of Cl_2 , both FeCl_2 and FeCl_3 are produced.

Ferrous chloride FeCl_2 . (*Iron dichloride* or *protochloride*.) Mol. w. 126.64 (v. *infra*). S.G. 2.528 (Fihol, *A. Ch.* [3] 21, 415); 2.988 at 17.9° (Clarke's *Specific Gravity Tables* [new ed.] 24). V.D. 62.79 at 1300° – 1400° ; 61.55 at 1400° – 1600° (Nilson a. Pettersson, *C. J.* 53, 828). V.D. at yellow-heat 94.4 (V. Meyer, *B.* 17, 1335), calc. for FeCl_2 , 68.32; for Fe_2Cl_4 , 126.64 (v. *infra*). H.F. $[\text{Fe}, \text{Cl}] = 82,050$; $[\text{Fe}, \text{Cl}^2, \text{Ag}] = 99,950$; $[\text{FeCl}_2, 4\text{H}^+\text{O}] = 15,150$ (*Th.* 8, 293).

Formation.—1. By heating excess of Fe filings

or wire in Cl.—2. By partially reducing FeCl_3 in H (Wöhler, *A.* 4, 255).—3. By dissolving Fe in HClAq out of contact with air, evaporating, and drying in a stream of H.—4. By heating Fe filings with NH_4Cl out of contact with air.

Preparation.—Fe wire is heated in a stream of dry HCl, and the product sublimed in the same gas (Wöhler & Liebig, *P.* 21, 258).

Properties and Reactions.—White, lustrous, six-sided, deliquescent, tablets. Heated very strongly in N forms FeCl_2 and Fe (V. Meyer, *B.* 17, 1835). Heated in O, forms Fe_2O_3 , with evolution of Cl. Oxidises readily in air to a mixture of FeCl_2 and Fe_2O_3 . Heated to redness in steam forms Fe_2O_3 , HCl, and H. Heated to redness in a stream of NH_3 , Fe_3N_2 is produced (Fremy, *C. R.* 52, 321). Heated with PH_3 forms HCl and Fe phosphide. A mixture of FeCl_2 and Cl is reduced by Zn vapour with separation of Fe in crystals (Poumarède, *C. R.* 29, 520). S. c. 50 at 80° ; less sol. in HClAq .

Molecular weight of gaseous ferrous chloride. By volatilising in HCl at a yellow heat, V. Meyer got values for V.D. which were about the mean between those calculated for FeCl_2 and Fe_2Cl_3 (*B.* 17, 1335); calculated for FeCl_2 = 63.32, for Fe_2Cl_3 = 126.64; observed 92.32 and 96.51. Meyer concluded that molecules of Fe_2Cl_3 probably exist at lower temperatures and molecules of FeCl_2 at a very high temperature. Nilson & Pettersson (*C. J.* 53, 827) obtained values for V.D. at c. 1400° agreeing with that calculated for FeCl_2 ; calculated = 63.32, observed at 1300° = 62.79, at 1400° = 61.55. There can be no doubt but that molecules of the composition FeCl_2 exist at c. 1300° – 1500° .

Combinations.—1. With water to form the hydrates $\text{FeCl}_2 \cdot 2\text{H}_2\text{O}$ and $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$. The former is obtained by saturating warm conc. HClAq with FeCl_2 , or by passing HCl into saturated FeCl_2Aq ; the latter is produced by dissolving Fe in HClAq and concentrating out of contact with air. $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ forms blue-green, monoclinic, deliquescent, transparent crystals; S.G. 1.93.—2. With nitric oxide; solution of FeCl_2 , especially an alkaline solution, absorbs NO forming a green-brown liquid which contains $\text{FeCl}_2 \cdot \text{NO}$; NO is removed by warming.—3. With ammonia to form $\text{FeCl}_2 \cdot 6\text{NH}_3$ and $8\text{FeCl}_2 \cdot 2\text{NH}_3$ (Rogstadius, *J. pr.* 86, 810). The former is a white powder, produced by passing NH_3 over FeCl_2 at the ordinary temperature; the latter is formed by slowly heating $\text{FeCl}_2 \cdot 6\text{NH}_3$ to melting. By strongly heating $8\text{FeCl}_2 \cdot 2\text{NH}_3$ in NH_3 , the nitride Fe_3N_2 is formed (Fremy, *C. R.* 52, 321).—4. With ammonium chloride to form $\text{FeCl}_2 \cdot 2\text{NH}_4\text{Cl}$; obtained by crystallising mixed solutions of FeCl_2 and NH_4Cl , or, according to Hisinger & Berzelius (*G. A.* 27, 278) (with evolution of NH_3 and H), by boiling Fe filings with NH_4ClAq (cf. Winkler, *R. P.* 69, 171; Vogel, *J. pr.* 2, 192). A compound $\text{FeCl}_2 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$ is also known (Schabus, *W. A. B.* 1850, 475). Compounds with CdCl_2 and HgCl_2 , viz. $\text{FeCl}_2 \cdot 2\text{CdCl}_2 \cdot 12\text{H}_2\text{O}$ and $\text{FeCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$, also described (v. Hauser, *W. A. B.* 17, 831).

FERRIC CHLORIDE. (Iron sesquichloride or perchloride.) FeCl_3 . Mol. w. 162.01, and probably also 324.02 (v. infra). (280° – 285°) (Friedel & Crafts, *C. R.* 107, 801). S.G. 2.804 at 10.8° (Clarke's Tables of Specific Gravity [new ed.],

24). V.D. varies from a. 165 at 320° to c. 80 at 1000° – 1800° (v. infra). Crystallises in hexagonal forms a:c = 1:1.235, Nordenskiöld (v. Hammelsberg's *Hand. der Krystalphysikal. Chemie*, 1, 260). H.F. [FeCl_3] = 96,040; [$\text{FeCl}_3 \cdot \text{Cl}$] = 18,990; [$\text{FeCl}_3 \cdot \text{Aq}$] = 127,720; [$\text{FeCl}_3 \cdot \text{Aq} \cdot \text{Cl}$] = 27,770 (Th. 8, 293).

Occurrence.—In the craters of volcanoes.

Formation.—1. By heating Fe in a stream of Cl.—2. By heating FeCl_2 in Cl.—3. By strongly heating FeCl_2 in a wide-mouthed vessel; Fe_2O_3 remains and FeCl_3 sublimes.—4. By passing HCl over strongly heated amorphous Fe_2O_3 (Deville & Troost, *C. R.* 45, 821).—5. By heating a mixture of calcined FeSO_4 with CaCl_2 or NaCl . The product obtained by boiling down a solution of Fe_2O_3 in HCl always contains oxychloride.

Preparation.—Fine iron-wire is strongly heated in a hard-glass tube in a stream of dry Cl, and the product is sublimed in the same gas.

To prepare a solution of FeCl_3 , a hydrated Fe_2O_3 is dissolved in hot HClAq , the solution is decanted, Cl is passed in until K_2FeCl_6 ceases to give any trace of blue colour, and excess of Cl is removed by warming; or 2 parts warm HClAq are saturated with Fe (filings or wire), to the clear decanted liquid 1 part HClAq is added, the liquid is warmed and HNO_3Aq is added little by little until all FeCl_2 is oxidised to FeCl_3 ; excess of HNO_3 is removed by evaporation with a little HClAq . Geissler (*Ar. Ph.* [2] 58, 159) recommends to evaporate the ferrous solution to S.G. 1.3 at 17° and then to add HNO_3Aq to the cold solution, when oxidation proceeds rapidly.

Properties.—By slowly cooling the vapour, FeCl_3 condenses in hexagonal crystals which appear very dark red by transmitted, and greenish by reflected, light (Deville & Troost, *C. R.* 45, 821). As ordinarily prepared FeCl_3 forms a brownish-black crystalline mass. Volatilises at somewhat over 100° . Melts at 306° – 307° in a sealed tube (Carnelley & Williams, *C. J.* 97, 126). Deliquescent; conc. solution in water is dark brown and somewhat acid; it becomes limpid and yellow on dilution; a very dilute solution is colourless when cold (v. Reactions, No. 4).

Franz (*J. pr.* [2] 5, 288) gives the following table showing S.G. and percentage composition of FeCl_3Aq at 17.5° :—

S.G.	p.p. FeCl_3	S.G.	p.p. FeCl_3	S.G.	p.p. FeCl_3
1.0146	2	1.1746	22	1.8870	42
1.0292	4	1.1950	24	1.4118	44
1.0439	6	1.2155	26	1.4387	46
1.0578	8	1.2365	28	1.4617	48
1.0734	10	1.2568	30	1.4876	50
1.0894	12	1.2778	32	1.5158	52
1.1054	14	1.2988	34	1.5439	54
1.1215	16	1.3199	36	1.5729	56
1.1378	18	1.3411	38	1.6028	58
1.1542	20	1.3622	40	1.6317	60

Schult (*Forth. Skand. Naturf.* 1868, 452) obtained the following results at 14.6° :—

S.G. FeCl_3Aq	p.p. FeCl_3	S.G. FeCl_3Aq	p.p. FeCl_3
1.0882	4.65	1.359	38.25
1.0918	10.45	1.3824	38.95
1.1518	18.80	1.4361	41.0
1.2107	22.54	1.554	49.81
1.2818	24.60		

FeCl_3 is soluble in alcohol or ether; the solution

easily decomposes in sunlight with formation of FeCl_2 .

Molecular weight of gaseous ferric chloride.—Deville & Troost (*A. R.* 45, 821) found the V.D. of ferric chloride at 440° to be 162.7; this corresponds to the formula Fe_2Cl_6 . Grönwald & V. Meyer (*B.* 21, 687) made a series of determinations of V.D. in an atmosphere of N, with the following results: 161.75 at 448° (mean of 4), 139.5 at 518° (mean of 8), 121.3 at 606° (mean of 6), 78.68 at 750° (mean of 2), 71.2 at 1036° , 77.6 at 1077° , 74.3 at 1300° . These numbers seem to indicate a gradual resolution of molecules of Fe_2Cl_6 into FeCl_3 ; none of the results, however, agrees exactly with the value calculated for FeCl_3 (81.005), but this was to be expected, as G. a. M. showed that even at 518° ferric chloride is partially resolved into FeCl_2 and Cl in an atmosphere of N. According to Friedel & Crafts (*C. R.* 107, 301) ferric chloride is not dissociated at 440° in an atmosphere of Cl; F. a. C. made a series of determinations of V.D. in Cl, using a modification of Dumas' method; the results are appended:— 165.1 at 321.6° , 180.4 at 325.2° , 174.2 at 356.9° , 171.5 at 357° , 168.7 and 169.5 at 442.2° . These values are all somewhat greater than 162.1, the value required by the formula Fe_2Cl_6 . The most probable conclusion from all the results seems to be that at high temperatures, c. 700° and upwards, the vapour of ferric chloride consists of molecules of FeCl_3 , but that as temperature falls these molecules are mixed with more complex molecules, some of which at any rate have the composition Fe_2Cl_6 (*cf.* Young, *N.* 39, 198).

Reactions.—1. When FeCl_3 is heated in oxygen, Fe_2O_3 and Cl are produced (*cf.* Schulze, *J. pr.* [2] 21, 407).—2. Heated in hydrogen, FeCl_2 is formed (Wöhler, *A. Suppl.* 4, 255).—3. Heated in water-vapour, Fe_2O_3 and HCl are formed.—4. FeCl_3 dissolves in water; the conc. solution is a syrupy dark-brown liquid, becoming yellow on dilution, and colourless when very dilute and cold. By heating FeCl_3 aq. colloidal soluble $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ and HCl are produced; fairly conc. FeCl_3 aq. forms oxychlorides, $\text{Fe}_2\text{O}_3 \cdot x\text{FeCl}_3$, at c. 100° , and at higher temperatures Fe_2O_3 is formed. The amount of decomposition and the composition of the products depend on the concentration of the solution and the temperature; very dilute solutions, c. 30,000 parts to 1 FeCl_3 , are decomposed with formation of colloidal soluble ferric hydrate even without warming (*cf.* *Iron, hydrated oxides or hydroxides of*, p. 59). Krecke (*J. pr.* [2] 8, 286) gives the following table (*cf.* Tichborne, *C. N.* 23, 123, 199, 209, 280; 25, 133; Müller, *J.* 1873, 40; Fournersau, *C. R.* 103, 42):—

P. c. FeCl_3 in solution. p. c.	Formation of Graham's colloidal hydrate	
82	100-180	
5	100-120	FeCl_3 re-formed
3	100-110	on cooling
1	90-100	
1	87	
1	83	
5	75	FeCl_3 not re-formed
25	64	on cooling
125	64	
625	80	

FeCl_3 aq. containing 1 p. c. FeCl_3 or less is decomposed by light at $5^\circ-6^\circ$ (Krecke, *l.c.*). When FeCl_3 aq. is heated in a sealed tube to $250^\circ-300^\circ$ it decomposes to Fe_2O_3 and HCl (Stenarmont, *C. R.* 32, 762). From a very dilute cold colourless solution of FeCl_3 , K_2FeCl_6 aq. ppt. a pure blue pp., and NaCl produces no change. If the solution is heated it becomes yellow, and contains soluble ferric hydrate and HCl. From this solution K_2FeCl_6 aq. ppt. greenish-blue solid, and on addition of NaCl a soluble ferric hydrate separates, which, after long contact with NaCl aq., becomes insol. in water (Debray, *C. R.* 68, 913). Evaporation of FeCl_3 aq. is accompanied by evolution of some HCl; the residue contains oxychloride or hydrated oxide. FeCl_3 is not volatilised from violently boiling FeCl_3 aq. containing HCl (Fresenius, *Fr.* 6, 92). G. Wiedemann connects the decomposition of FeCl_3 aq. and also of other ferric salts, with the different magnetic behaviour of colloidal soluble $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, and that hydrate which remains in combination with the acid (*W.* 5, 45).—5. FeCl_3 dissolves in alcohol or ether. An ethereal solution mixed with alcohol and allowed to stand in sunlight loses its yellow colour, and FeCl_2 and chlorinated derivatives of alcohol and ether are formed.—6. An aqueous solution of FeCl_3 is readily reduced to FeCl_2 , e.g. by As, Sb, Bi, Fe, Pb, or Zn; also by finely-divided Pt, more slowly by Pd and Au (*cf.* Béchamp, *C. R.* 52, 757; Saint-Pierre, *C. R.* 54, 1077). Also reduced by stannous chloride, sulphurous acid, or sulphuretted hydrogen; hydriodic acid reduces dilute FeCl_3 aq. slowly (*v.* Mohr, *A.* 105, 53). Many organic compounds also reduce FeCl_3 aq., especially in sunlight, e.g. alcohol and ether, or tartaric acid (*v.* Schorax, *B.* 8, 11; Poitevin, *C. R.* 52, 94).—7. A very little FeCl_3 is said to be formed by passing hydrogen for 48 hours through FeCl_3 aq. (Brunner, *J.* 1864, 125).—8. FeCl_3 dissolves freshly ppd. ferric hydrate forming oxychlorides (*q. v.*).—9. When FeCl_3 aq. is dropped into solution of potassium nitrite, in an atmosphere of CO_2 , brisk evolution of NO proceeds, and a pp. of soluble ferric metahydroxide, $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, separates (Pesci, *G.* 18, 168).—10. FeCl_3 aq. reacts with potassium iodide to form FeCl_2 , I, and KCl; probably FeI, is at first produced, and is then resolved into FeI, and I, and then the FeI, reacting with unchanged FeCl_3 , forms FeCl_2 and I (*v.* Carnegie, *C. N.* 30, 87).—11. When electrolysed, conc. FeCl_3 aq. gives FeCl_2 at the negative, and Cl with a little O at the positive, electrode.

Combinations.—1. With water to form various hydrates: (1) $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$; yellow solid, formed by dissolving 100 parts FeCl_3 in 68.5 parts H_2O (S.G. of solution 1.67 at 25°); or by slowly eva-

porating FeCl_2Aq on the water-bath, and allowing to crystallise; or by exposing FeCl_2 to the air (Mohr, *A.* 29, 178); or by passing HCl over commercial ferric chloride, filtering the liquid which forms through glass wool, and evaporating over KOH *in vacuo* (Engel, *C. R.* 104, 1708); melts at 35.5° , and solidifies again at 28° (Ordway, *Z.* 1866, 23). (2) $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$; reddish tablets, melting at 81° , formed by melting the hexahydrate, warming to 100° , for some hours, and cooling slowly (Engel, *loc. cit.*); or by evaporating FeCl_2Aq to a syrup (S.G. c. 1.5), with addition of a little HClAq , and crystallising (Fritzsche, *J. pr.* 18, 479; Goble, *J. Ph.* [3] 5, 801; 25, 259). According to Wittstein (*R. P.* [2] 86, 80) and Ordway (*Z.* 1866, 23), the hydrate thus obtained is $\text{FeCl}_2 \cdot 3\text{H}_2\text{O}$. The hydrate $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$ is said to be formed by placing $\text{FeCl}_2 \cdot 6\text{H}_2\text{O}$ over H_2SO_4 ; the hexahydrate at first liquefies and then loses water.—2. With *hydrogen chloride and water*, to form $\text{FeCl}_2 \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$; thin, transparent, amber-yellow laminae, formed by passing dry HCl gas over $2\text{FeCl}_2 \cdot 5\text{H}_2\text{O}$, saturating the liquid thus produced with HCl at 25° , and cooling to 0° (Engel, *C. R.* 104, 1708; Sabatier, *Bl.* 1881, 197).—3. With *ammonia*, to form $\text{FeCl}_2 \cdot \text{NH}_3$. When heated, this compound partly sublimes, and is partly decomposed, giving FeCl_3 .—4. With *phosphoric chloride*, to form a brown fusible compound, $\text{FeCl}_2 \cdot \text{PCl}_3$ (Weber, *J. pr.* 76, 410).—5. With *hydrocyanic acid*, to form a brown liquid, which then crystallises to $\text{FeCl}_2 \cdot 2\text{HCN}$ (Klein, *A.* 74, 97).—6. With *cyanogen chloride*, but the compound has not been obtained pure (*v. Klein, loc. cit.*).—7. With *nitrosyl chloride*, to form $\text{FeCl}_2 \cdot \text{NOCl}$; a dark-coloured, very deliquescent mass, obtained by placing dry FeCl_2 in the fumes of *aqua regia* placed over CaCl_2 (Weber, *J. pr.* 89, 152).—8. With *alkali chlorides*, to form $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$; $\text{M} = \text{K}, \text{Na}, \text{Rb}, \text{NH}_4$. The NH_4 compound forms garnet-red crystals; by evaporating rixed solutions of the constituent salts. The crystals are rhombic according to Fritzsche (*J. pr.* 16, 484), dimorphous according to Genth (*J. pr.* 71, 164). The double compounds $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$ are all decomposed by water. The K salt is described by Fritzsche (*J. pr.* 18, 483), the Na salt by Deville (*C. R.* 43, 970), the Rb salt, said to be $\text{FeCl}_2 \cdot 3\text{RbCl}$, by Godeffroy (*Ar. Ph.* [3] 9, 343). According to Kremers (*J. pr.* 55, 191), a compound of the form $\text{FeCl}_2 \cdot 2\text{MCl} \cdot \text{H}_2\text{O}$, in which M is partly K (12.1 p.c.), partly Na (16 p.c.), and partly NH_4 (4.3 p.c.), is found in certain volcanic craters.—9. With *thallium chloride*, to form $\text{FeCl}_2 \cdot 3\text{TlCl}$ (Wöhler & Ahrens, *id.* 144, 250).—10. With *magnesium and beryllium chlorides*, to form $\text{FeCl}_2 \cdot \text{MCl} \cdot \text{H}_2\text{O}$; formed by adding MgCl_2 or BeCl_2 to a conc. hot solution of FeCl_2 in HClAq (Neumann, *A.* 244, 323).

FERRICO-FERRIC CHLORIDE Fe_2Cl_3 ($\text{FeCl}_2 \cdot 2\text{FeCl}_3$). When $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is treated with a little HClAq , FeCl_3 goes into solution, and Fe_2O_3 remains; but $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ dissolves wholly in considerable excess of conc. HClAq . When the solution is cooled and placed *in vacuo* over H_2SO_4 , yellow crystals of $\text{Fe}_2\text{Cl}_3 \cdot 18\text{H}_2\text{O}$ are said to separate (Lefort, *C. R.* 65, 179). The crystals are deliquescent; at 50° they lose water; heated to 90° HCl is given off and O absorbed; by warming an aqueous solution of the crystals, FeCl_3 and FeCl_2 are formed.

Iron, cyanides of. No cyanides of iron have been isolated, but *ferric* and *ferro-cyanides* are numerous; *v. vol. ii.* pp. 332, 334, 338.

Iron, ferrieyanide and ferrocyanide of. *v. vol. ii.* pp. 334 a, 338.

Iron, fluorides of. Two fluorides of Fe are known, FeF_2 and FeF_3 . The former is produced by dissolving Fe in HFAq , the latter by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HFAq .

Ferrous fluoride FeF_2 . Small green crystals of this composition separate from a solution of Fe in HFAq (Scheurer-Kestner, *A. Ch.* [3] 68, 472). By careful heating, FeF_2 is obtained as a white solid. FeF_2 is unchanged by heat; the hydrate is partly decomposed to HF and Fe_2O_3 . Slightly sol. in water, more easily on addition of HF. The double salt $\text{FeF}_2 \cdot 2\text{KF}$ is a green pp., obtained by adding KFAq to FeSO_4Aq ; the salts $\text{FeF}_2 \cdot \text{KF} \cdot 2\text{H}_2\text{O}$, $\text{FeF}_2 \cdot 2\text{NH}_4\text{F}$, and $\text{FeF}_2 \cdot \text{NH}_4\text{F} \cdot 2\text{H}_2\text{O}$ are described by Wagner (*B.* 19, 896). The *silicofluoride* $\text{FeF}_2 \cdot \text{SiF}_4 \cdot (-\text{FeF}_2\text{F})$ is said to be formed as blue-green crystals by dissolving Fe in $\text{H}_2\text{SiF}_6\text{Aq}$ and crystallising (Wurtz, *Dictionnaire*, i, 1403).

Ferric fluoride FeF_3 . Crystals of the hydrate $2\text{FeF}_3 \cdot 9\text{H}_2\text{O}$ are obtained by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HFAq and evaporating, or by oxidising FeF_2 in HFAq by HNO_3 . The crystals are yellowish according to Berzelius, colourless according to Scheurer-Kestner (*A. Ch.* [3] 68, 472). At 100° $3\text{H}_2\text{O}$ is removed; at higher temperatures H_2O and HF escape. By heating the salt dried at 100° in a Pt crucible colourless crystals of FeF_3 are formed on the surface of the mass, isomorphous with AlF_3 (Deville, *C. R.* 43, 970). Slowly dissolved by water; addition of NH_4Aq ppt. the *oxyfluoride* $3\text{Fe}_2\text{O}_3 \cdot 2\text{FeF}_3 \cdot 4\text{H}_2\text{O}$. FeF_3 forms double salts with K, Na, and NH_4 ; these are obtained by adding FeF_3Aq to solutions of the alkali fluorides; the salts described are $\text{FeF}_3 \cdot 3\text{KF}$ (Berzelius; Wagner, *B.* 19, 896); $2\text{FeF}_3 \cdot 4\text{KF} \cdot \text{H}_2\text{O}$ (Nicklés, *Z.* 7, 480); $\text{FeF}_3 \cdot 3\text{NaF}$ (*B.*; W., *loc. cit.*); $\text{FeF}_3 \cdot 2\text{NaF}$ (Nicklés, *J.* 1869, 268); $\text{FeF}_3 \cdot 2\text{NH}_4\text{F}$ (*N., loc. cit.*), to this salt Marignac gives the formula $\text{FeF}_3 \cdot 3\text{NH}_4\text{F}$ (*A. Ch.* [3] 60, 306).

Iron, haloid compounds of. Iron readily combines with the halogens. With each halogen, two compounds are formed, ferrous FeX_2 and ferric FeX_3 ; ferric iodide, however, has not been isolated with certainty; the compound Fe_2Cl_4 , corresponding to Fe_2O_3 , also perhaps exists. The only compounds that have been gasified are ferrous and ferric chloride. The former has the molecular formula FeCl_2 at 1800° – 1500° ; but there are indications of the possible existence of molecules of Fe_2Cl_4 at lower temperatures; the latter appears to exist as a gas both as Fe_2Cl_4 and FeCl_2 . The haloid compounds of Fe are soluble in water; solutions of FeBr_2 and FeCl_2 are decomposed by much water; the compounds all form several double compounds with the chlorides &c. of the more positive metals.

Iron, hydrides of. No definite hydride of Fe has been certainly isolated, but there are several indications of the existence of a compound or compounds of Fe and H. Fe heated to redness absorbs about .46 vols. H (Deville & Troost, *C. R.* 57, 966; 59, 102). Electrolytically deposited Fe contains H along with N, CO, and CO_2 (Lenz, *P. Ergänzbd.* 5, 252; cf. Meidinger,

D. P. J. 168, 283; Chandler-Jobert, *C. N.* 31, 185. Iron wire takes up H when immersed in dilute $\text{H}_2\text{SO}_4\text{aq}$ (Johnson, *Pr.* 23, 168; Reynolds, *C. N.* 29, 118). According to Caillaud (*C. R.* 80, 319) Fe ppd. electrolytically from neutral FeCl_2aq containing NH_4Cl gives off 225-233 vols. H when heated *in vacuo*. Observations on the supposed existence of a gaseous hydride of Fe were made by Thomson, Dupasquier (*C. R.* 14, 511), and Reinsch (*J.* 1858.190). The non-existence of such a gas was proved by Fresenius a. Schlossberger (*A.* 51, 415) and by Erlenmeyer (*N. J. P.* 9, 97). Thoma has investigated the conditions under which H is absorbed by Fe (*Z. P. C.* 3, 91). He finds that when Fe is made the negative electrode in a voltammeter, or when it is placed in dilute $\text{H}_2\text{SO}_4\text{aq}$, it absorbs much H, but that Fe placed in an atmosphere of H does not absorb any of that gas; a certain portion of the H absorbed is given off again on exposure to air or immersion in water, the rest of the H is more firmly retained by the Fe. According to Wanklyn a. Carius (*A.* 120, 69) when Fe reacts with ZnEt_2 in presence of ether, various gases including C_2H_2 , C_2H_4 , C_2H_6 , and H are evolved, and a metal-like powder remains, which, after washing with ether, is decomposed by H_2O giving H and a mixture of H and FeO. They regard this powder as a hydride of Fe, perhaps FeH_2 , but no analyses are given.

Iron, hydrated oxides or hydroxides of. Compounds with water of each of the three oxides of iron are known. The compositions of the various hydrated oxides are differently represented by different chemists; they appear to vary with small changes of conditions, so that it is impossible to say whether all the bodies described are true hydrates or not. The readiness with which most of the hydrated oxides undergo change of composition points to their being hydrates, i.e. compounds of water, rather than hydroxides, i.e. compounds of OH. Thomsen (*Th.* 3, 293) gives the thermal data: $[\text{Fe}^+, \text{O}^-, 3\text{H}^+\text{O}] = 191,150$; $[2\text{FeO}^+\text{H}^+, \text{O}^-, \text{H}^+\text{O}] = 54,590$; $[\text{Fe}^+, \text{O}^-, \text{H}^+\text{O}] = 68,280$; $[\text{FeO}^+\text{H}^+, \text{H}^+\text{SO}^+\text{Aq}] = 24,920$; $[\text{Fe}^+\text{O}^+\text{H}^+, 3\text{H}^+\text{SO}^+\text{Aq}] = 33,840$.

Only one hydrate of ferrous oxide, $\text{FeO} \cdot \text{H}_2\text{O}$, appears to exist; but it is doubtful whether any hydrate of this oxide has been obtained free from hydrates of Fe_2O_3 . Descriptions are given of two hydrates of ferroso-ferric oxide, viz. $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$; but here again there is great doubt as to the composition of the substances described as definite hydrates. Many hydrates of ferric oxide have been obtained; the following are known as minerals ($\text{M} = \text{Fe}_2\text{O}_3$): $\text{M} \cdot \text{H}_2\text{O}$, $\text{M} \cdot 2\text{H}_2\text{O}$, $\text{M} \cdot 3\text{H}_2\text{O}$, $2\text{M} \cdot \text{H}_2\text{O}$, $2\text{M} \cdot 3\text{H}_2\text{O}$, $3\text{M} \cdot 5\text{H}_2\text{O}$; the following are said to have been obtained artificially: $\text{M} \cdot \text{H}_2\text{O}$, $\text{M} \cdot 2\text{H}_2\text{O}$, $\text{M} \cdot 3\text{H}_2\text{O}$, $2\text{M} \cdot \text{H}_2\text{O}$, $2\text{M} \cdot 3\text{H}_2\text{O}$; many of these appear to exist in different modifications each distinguished by special properties; broadly they fall into two classes, those which are insoluble in water, and those which dissolve in water.

HYDRATE OF FERROUS OXIDE $\text{FeO} \cdot \text{H}_2\text{O}$. The white pp. obtained by adding air-free KOHAq to an air-free solution of a ferrous salt, and washing out of contact with air, is probably $\text{FeO} \cdot \text{H}_2\text{O}$. To obtain the pp. nearly free from ferric oxide Schmidt (*A.* 86, 101) ppt. in a closed flask,

allows pp. to settle, draws off water by a syphon, carefully pours warm water which has been boiled for some time on to the surface of the cold water in the flask, withdraws water by a syphon, &c.; he then quickly transfers the moist pp. by a syphon to a retort containing ether, and having attached to it a long glass tube dipping under Hg, the ether covers the pp. and drives the air out of the retort; on warming, the water-vapour and condensed water escape through the Hg. When the ether is removed and the retort is cold, dry air-free H (not CO_2 , as the hydrate combines with this gas) is passed through the apparatus, and portions of the solid are transferred in an atmosphere of H to small wide-mouthed stoppered tubes. Dried in this way, the hydrate is a pale-greenish, friable solid, which rapidly oxidises and glows in the air.

A. de Schulten (*C. R.* 109, 266) states that $\text{FeO} \cdot \text{H}_2\text{O}$ may be obtained in green six-sided flat prisms, which almost instantly become red in air, by mixing 5 grams FeCl_2 dissolved in 100 c.c. air-free water, and 200 c.c. NaOHAq, containing 20 grams NaOH, in a flask filled with coal gas, heating, and allowing to stand for 24 hours.

According to Bineau (*C. R.* 41, 509) ferrous hydrate is soluble in c. 150,000 parts water. Ferrous hydrate is very easily oxidised; it is therefore an energetic reducer, e.g. it reduces salts of Au, Ag, and Pt, and also HIO_3aq . It dissolves in acids to form ferrous salts FeX_2 ;

$\text{X} = \text{NO}_3, \text{SO}_4, \text{PO}_4, \text{&c.}$ (cf. Ferrous oxide,

under Iron, oxides of).

HYDRATES OF FERROSO-FERRIC OXIDE $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$; composition of both doubtful. Hydrates of Fe_2O_3 are produced by ppg. a mixture of equivalent quantities of a ferrous and ferric salt by alkali, and also by digesting ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ with Fe. The black powder obtained by Wöhler (*A.* 28, 92) by ppg. a mixture of equivalent parts of ferrous and ferric sulphates by slight excess of NH_4Aq , boiling, washing by decantation, and drying under 100° is said, by Lefort (*C. R.* 69, 174) to be $\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$. By ppg. a mixture of equivalent quantities of a ferrous and ferric salt by hot conc. KOHAq, Lefort (&c.) obtained a hydrate more stable than that got by using NH_4Aq ; to this hydrate he gives the formula $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. The black hydrate obtained by digesting $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ with Fe under water does not seem to have been analysed (v. Preuss, *A.* 26, 96). Ferroso-ferric hydrates are described as brown-black, magnetic, brittle, powders; when heated out of contact with air they give Fe_2O_3 ; heated in air, Fe_2O_3 is produced. Ferroso-ferric hydrates dissolve in acids to produce mixtures of ferrous and ferric salts; in some cases definite salts of the form Fe_2X_3 , $\text{X} = \text{SO}_4, \text{&c.}$, are formed, according to Lefort (*C. R.* 69, 179) (cf. Ferroso-ferric oxide, under Iron, oxides of).

HYDRATES OF FERRIC OXIDE. A great many supposed hydrates of Fe_2O_3 have been described, but there is much doubt as to the composition and properties of definite hydrates of the form $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$. The following occur as minerals, the compositions of which more or less accurately agree with the formulae:—limonite $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, and $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$;

göthite $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$; *turgite* $2\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $8\text{Fe}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. According to Ramsay (*C. J.* 82, 395), and Bressius (*J. pr.* [2] 3, 272), the pp. obtained by adding alkali to a ferric salt, either hot or cold, washing, and drying at 100° , is $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$; by ppg. FeCl_3Aq with NH_3Aq , washing first with water and then with alcohol and ether, and drying at 100° the hydrate $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ is obtained, according to Bressius (*l.c.*). Wittstein (*C. O.* 1853, 367) says that the hydrate obtained by ppg. a ferric salt by NH_3Aq , washing with cold water, and drying at a gentle heat, or at 100° for a short time, is $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. The experiments of Carnelley & Walker (*C. J.* 53, 89) on the dehydration of ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ through a range of temperature showed that the pp. after drying at 15° for 18 days contained more water than is required by $\text{Fe}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, that when heated to 55° the residue had the composition $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, but that water was gradually and continuously given off from 15° upwards until Fe_2O_3 was formed at 500° ; the composition, however, remained constant from 385° to 415° , and corresponded with the formula $10\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. Van Bemmelen (*R. T. C.* 7, 106) has examined the composition of the colloidal pp. by adding NH_3Aq to FeCl_3Aq ; his experiments, which were very extended, showed the great readiness with which the ratio of Fe_2O_3 to H_2O varies; e.g. exposed to air for a year the composition became constant, with the ratio $\text{Fe}_2\text{O}_3 : 4$ or $4\frac{1}{2}\text{H}_2\text{O}$; after 4 months in dry air the ratio was $\text{Fe}_2\text{O}_3 : 1\frac{1}{2}\text{H}_2\text{O}$; heated to 100° in dry air the ratio was $\text{Fe}_2\text{O}_3 : 96\text{H}_2\text{O}$; the same sample kept for 6 years in a closed flask and then heated to 15° until constant gave $\text{Fe}_2\text{O}_3 : \text{H}_2\text{O}$; at 100° $\text{Fe}_2\text{O}_3 : 45\text{H}_2\text{O}$; between 100° and 300° the final state was $\text{Fe}_2\text{O}_3 : 25\text{H}_2\text{O}$; and so on. Besides the papers referred to above on the composition of ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, the following are of importance:—Lefort (*J. pr.* 54, 305); P. de Saint-Gilles (*J. pr.* 66, 137); Schaffner (*A.* 51, 177); Muck (*Z.* [2] 4, 51); Davies (*C. J.* [2] 4, 69); Tommasi (*B.* 12, 1929, 2334).

The *monohydrate* $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is said to be obtained: (1) by adding NaOHAq and KClOAq to boiling FeSO_4Aq , washing, and drying at 100° (Muck, *Z.* [2] 4, 41); (2) by keeping ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in contact with boiling water for 6–8 hours (P. de Saint-Gilles, *A. Ch.* [3] 46, 47); (3) by repeatedly melting NaOH in a cast-iron vessel and washing (Brunck & Gräbe, *B.* 13, 725); (4) by keeping ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ under water for many years at the ordinary temperature (Schiff, *O. C.* 1860, 1768). This hydrate also occurs native as *göthite*. $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is described as a dark-red powder; slowly dissolved by dilute warm HClAq , $\text{H}_2\text{SO}_4\text{Aq}$, or HNO_3 ; insol. in cold conc. acids. The monohydrate obtained by Brunck & Gräbe was in the form of small tabular, brownish-violet, hexagonal crystals; S.G. 2.91. Göthite forms rhombic crystals, S.G. 3.8 to 4.2. The monohydrate obtained by P. de Saint-Gilles, by keeping $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in contact with boiling water for 6–8 hours, is described as a brick-red powder, scarcely acted on by conc. boiling HNO_3Aq , slowly dissolved by conc. hot HClAq ; it dissolves in dilute HNO_3Aq , HClAq , or acetic acid, forming a red liquid which appears clear by transmitted, but

turbid by reflected, light, and is ppd. by a very small quantity of an alkali salt; on addition of conc. HNO_3Aq or HClAq , this solution gives a red pp. which dissolves on adding water. This modification of $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ does not form Prussian blue with K_2FeCy , and acetic acid.

The *dihydrate* $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ is said to be obtained by ppg. cold FeSO_4Aq by NaOHAq and KClOAq or $\text{H}_2\text{O}_2\text{Aq}$, washing, and drying at 100° (Weltzien, *A.* 138, 129; Muck, *l.c.*). This hydrate also occurs native as *limonite*.

The *hydrates* $2\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ and $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ are said to be formed by the action of water on ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$; the first by boiling for 100 to 1,000 hours, Davies (*C. J.* [2] 4, 66); the second by long-continued action of water at the ordinary temperature (Wittstein, *Ar. Ph.* 74, 156), or, crystalline, by freezing $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ suspended in water (Limberger, *C. O.* 1853, 783). By heating any of the hydrates in sealed tubes Fe_2O_3 is eventually produced (Sénarmont, *C. R.* 32, 762).

Muck (*Z.* 1868, 41) thinks that the ferric hydrates obtained by oxidising ferrous hydrate or carbonate in air differ essentially in properties from the ferric hydrates obtained directly from ferric salts. Tommasi (*Bl.* [2] 38, 452; T. a. Pellizzari, *Bl.* [2] 37, 196) arranges the ferric hydrates in two classes: the red hydrates obtained by ppg. ferric salts, by alkali, and the yellow hydrates obtained by oxidising hydrates of FeO or Fe_2O_3 , or by oxidising FeCO_3 .

Ferric hydrates give up O to readily oxidised compounds such as SO_3Aq , SnCl_2Aq ; in contact with decaying organic bodies the hydrates part with O, but again take it up if exposed to air; they absorb gases e.g. NH_3 and CO_2 (v. Reinhardt, *Fr.* 7, 187). They dissolve in acids to

form ferric salts FeX , $\text{X} = \text{NO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$, &c.

These hydrates when freshly ppd. also dissolve in FeCl_3Aq forming oxychlorides (q. v.) (*v. Ferric oxide, under Iron, oxides of*, p. 62).

SOLUBLE FERRIC HYDRATES. A modification of $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ soluble in water was prepared by P. de Saint-Gilles in 1855 (*A. Ch.* [3] 46, 47). Ordinary ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ is dissolved in acetic acid, the solution is heated to 100° for a long time in a closed vessel; the blood-red colour of the liquid changes to brick red, the liquid appears opalescent in reflected light, and the taste is no longer metallic but merely that of acetic acid; on now adding conc. HClAq or HNO_3Aq , or the merest trace of $\text{H}_2\text{SO}_4\text{Aq}$ or an alkali salt, the whole of the Fe is thrown down as a brown-red curdy pp., which, when dried off a porous tile, appears as a brown, lustrous, varnish-like solid, having the composition $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. This modification of ferric hydrate, sometimes called *ferric metahydrate*, is insol. in conc. acids, but dissolves easily in water, forming a deep-yellow, opalescent, tasteless liquid, unchanged by K_2FeCy , or KONS . Traces of H_2SO_4 or alkali salts, and also conc. HClAq or HNO_3Aq , ppt. the hydrate from its aqueous solution. The same hydrate has been obtained by Scheurer-Kestner by prolonged heating in aqueous solution of basic ferric nitrate in a sealed tube at 100° (*C. R.* 48, 1180); also by Debray by heating dilute FeCl_3Aq to 100° (*C. R.* 68, 913; cf. *Ferric chloride, Reactions*,

No. 4, p. 35). Another soluble modification of ferric hydrate, sometimes called *dialysed* or *colloidal ferric hydrate*, is obtained by dialysing a solution of FeCl_3 containing $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ so long as the dialysate contains HCl (Graham, *Tr.* 1861, 188). The solution is prepared by digesting FeCl_3 with $\text{ppd. Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, or by adding $(\text{NH}_4)_2\text{CO}_3$ to FeCl_3 so long as the pp. dissolves on stirring; the solution should contain 4-5 p.c. of solid matter, and have 5-6 equivalents of ferric hydrate in it. After dialysis a deep-red liquid is left on the dialyser; this liquid gelatinises by exposure to the air for some days, or by traces of H_2SO_4 , alkalis, alkaline salts, but not by HCl , HNO_3 , or acetic acid; the jelly-like mass thus obtained slowly becomes insol. in water, and is then sol. in dilute acids; it appears to be changed to the ordinary $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ (Graham, *loc. cit.*; cf. Shuttleworth, *Ph.* [3] 8, 545; Becquerel, *A.* 126, 208).

Kreka (*J. pr.* [2] 8, 286) has examined the formation of soluble ferric hydrates from FeCl_3 Aq. Formation of the colloidal hydrate occurs in FeCl_3 Aq containing $\frac{1}{10}$ to $\frac{1}{2}$ p.c. FeCl_3 at ordinary temperatures; solutions containing 8 to 32 p.c. must be heated to above 100° in closed tubes; on cooling the more conc. solutions (if not heated too long and too highly) re-formation of FeCl_3 occurs, but in solutions of less than 1 p.c. the base and acid remain uncombined on cooling. If a solution containing less than 1 p.c. is boiled for some time formation of ferric metahydrate begins, and after a time the hydrate is ppd. as an orange-yellow powder. A table showing the various products obtained by heating solutions of FeCl_3 Aq of different concentrations to different temperatures is given under *Ferric chloride*, *Reactions*, No. 4 (p. 55).

Iron, iodides of. Only one iodide of iron, FeI_3 has been isolated with certainty.

Ferrous iodide. (*Proto-iodide of iron.*) FeI_2 , $\text{H.F.} [\text{FeI}_2 \cdot \text{Aq}] = 47.650$ (*Th.* 3, 294). Fe and I combine by rubbing together with or without water; Fe and I heated together form a crystalline grey mass which melts at 177° (Carius a. Wanklyn, *A.* 120, 69). According to De Luca, FeI_2 is white, but goes green on addition of water (*C. R.* 55, 615). Green deliquescent crystals of $\text{FeI}_2 \cdot 5\text{H}_2\text{O}$, S.G. 2.873, are obtained by digesting 1 part Fe filings with 3-4 parts I in presence of water, adding Fe filings, evaporating out of contact with air, and filtering. FeI_2 , especially FeI_2 Aq, rapidly absorbs O with formation of oxyiodide (*q. v.*). Addition of sugar-syrup to FeI_2 renders the solution more stable. H_2O Aq decomposes FeI_2 with formation of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ and separation of all the I. FeI_2 Aq dissolves I; addition of K_2CO_3 to a solution containing $3\text{FeI}_2 : 2\text{I}$ forms KI and $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$; the solution may contain FeI_2 .

Ferric iodide. (FeI_3) This iodide has not been isolated; it is probably contained in a solution of FeI_2 to which I is added in the ratio $\text{FeI}_2 : \text{I}$. FeI_2 Aq containing I is separated by heating to FeI_3 and free I. Fleury (*J. Ph.* [5] 16, 529) says that the action of I on Fe in presence of water soon ceases if the temperature is kept down to 15° ; on filtering, only Fe_2O_3 is obtained; if, however, the mixture is boiled the red colour of the liquid disappears and a considerable quantity of Fe_2O_3 is found in the re-

sidue. A large excess of I is required to dissolve all the Fe, and a large excess of Fe is required to convert all the I into FeI_3 . F. supposes that FeI_3 is at first formed and is then decomposed by the heat to Fe_2O_3 and HI, and the HI then acts on the free Fe forming FeI_2 . Mohr observed that a very dilute solution of FeCl_3 (1 in 12,300) gives a blue colour on addition of starch and KI only after a considerable time (*A.* 105, 53). Nickles found that a solution of $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HIAq in presence of ether did not at once give a blue pp. with K_2FeCy_6 (*A. Ch.* [4] 5, 161; cf. Ordway, *Am. S.* [2] 26, 197). A solution made by digesting 126 parts I with sufficient iron, filtering, and adding 63 parts I, gives an apple-green pp. on addition of 201 parts citric acid previously neutralised by alkali carbonate (Creuse, *Ph.* [3] 3, 953). According to Carius a. Wanklyn (*A.* 120, 70) if Fe is heated with excess of I until a little I is vaporised, and the mass is allowed to cool in a covered crucible, I is suddenly evolved, and the residue consists of FeI_3 .

Iron, nitrides of. A nitride of Fe, Fe_3N_2 , is found as a silver-like lustrous deposit in the lavas of Etna (Silvestri, *P.* 157, 165); heated in H it yields Fe and NH_3 . Finely-divided Fe, prepared by heating ferrous oxalate or reducing Fe_2O_3 by H, takes up about 2 p.c. N when heated in N (Geuther a. Briegleb, *A.* 133, 228; Rogstadius, *J. pr.* 86, 307; Remsen, *Am.* 8, 184). By heating Fe in NH_3 , the Fe increases in weight 12-13 p.c. and becomes brittle (Berthollet, *G. A.* 30, 378). By electrolysis a mixture of NH_4Cl and a ferrous salt a lustrous deposit is obtained, supposed by Krämer to be a nitride of Fe with 1.5 p.c. N (*Ar. Ph.* [2] 105, 284), but said by Meidinger (*D. P. J.* 163, 288) to be an Fe-NH_3 amalgam. A nitride (or nitrides) of iron seems to be produced by heating FeCl_3 or FeCl_2 in NH_3 . The product is a brittle, grey-white, solid; heated alone it gives N and Fe; heated in H it gives NH_3 and Fe; it is slowly and partially decomposed by boiling water; sol. in acids with formation of H, ferrous and NH_3 salts; not acted on by Cl, Br, or I in presence of H_2O at ordinary temperatures, but when heated ferric and NH_3 salts are formed, and H, and probably also N, are evolved. The formula Fe_3N_2 agrees with most of the analyses; the formula Fe_2N_3 was given by Stahlschmidt (*P.* 125, 37; cf. Rogstadius, *J. pr.* 86, 307; Frémy, *C. R.* 52, 321).

Iron, nitroprusside of, *v. sol.* ii. p. 840.

Iron, nitrosulphides or nitrososulphides of. In 1858 Roussin obtained a salt by the reaction of NH_4HS and KNO_3 on FeCl_3 Aq, which contained Fe, but in which Fe could not be detected by the ordinary tests (*A. Ch.* [3] 52, 285). Proczinsky (*A.* 125, 302) obtained the same compound by adding NH_4HS to a solution of a ferrous salt saturated with NO. A similar salt was obtained by Pavel by using K_2S in place of NH_4HS (*B. M.* 1407). By treating these salts with alkali others were obtained more or less closely related to the original salts. The compounds thus obtained were analysed and examined by Roussin (*loc. cit.*), Proczinsky (*loc. cit.*), Rosenberg (*B.* 3, 312; 12, 1715), Demel (*B.* 12, 461), and Pavel (*B.* 12, 1407, 1949; 15, 2600). Roussin's analyses of the compound formed by using

NH₄HS led to the formula Fe₂S₂H₂(NO)₄; to the same compound Proczinsky gave the formula Fe₂S₂(NO)₄.2H₂O; and Rosenberg assigned the composition Fe₂S₂(NO)₄.4H₂O. In his second paper R. showed that the compound prepared by using K₂S contained K; this was confirmed by Pavel. All the observers admitted the presence of the NO group in these compounds.

Pavel (B. 15, 2600) has given an account of the compounds of which Roussin's salt is the type, and has indicated what appear to be their relations to other compounds of iron. As the compounds contain the group NO in addition to S they are better called nitroso- than nitrosulphides. Pavel regards the nitroso-sulphides of Fe as salts of acids, the acidic radicals of which are composed of Fe, NO, and S; the salts may be formulated generally as derived from the acids H₂Fe₂(NO)₂S₂. P. compares the ferrinitrososulphides with the ferrinitrosocyanides or nitroprussides, vol. ii. p. 340). According to P. there are two series of ferrinitrososulphides derived from the two acids HFe(NO)₂S₂ (or H₂Fe₂(NO)₂S₂), and HFe(NO)₂S (or H₂Fe₂(NO)₂S₂). The former acid has been isolated, the latter is not as yet known in the free state. The two series may perhaps be called ferrinitroso- and ferrinitroso-sulphides. In the following account of the salts Pavel's formulae are adopted:—

Series I. Ferrinitrososulphides

Potassium ferrinitrososulphide KFe(NO)₂S₂. A solution of KHS, made from 44 grams KOH in 400 c.c. water, is added to a boiling solution of 35 grams pure NaNO₂ in 400 c.c. water, the mixture is heated just to boiling, and a solution of 159 grams ferrous sulphate in 1200 c.c. water, to which a drop of dilute H₂SO₄ has been added, is allowed to flow into it with constant stirring; the liquid is kept warm on a water-bath, and is shaken from time to time until a greenish-red pp. (of Fe₂O₃, FeO, and S) forms on the sides of the flask, when the liquid is rapidly filtered, a little dilute KOHAq is added to it when cold, and it is allowed to stand for 48 hours. The salt which separates is dissolved in water at 70°, a little KOHAq is added as the liquid cools, and the crystals thus obtained are recrystallised in the same way, after standing 48 hours; the crystals are then dried over H₂SO₄ in *vacuo* protected from the light. About 30 grams of the pure salt are thus obtained. (Pavel, B. 15, 2601). If more KHS is used than directed above double sulphide of Fe and K are obtained and no nitrososulphide.

KFe(NO)₂S₂ crystallises in large, nearly black, lustrous, rhombic prisms; it is fairly stable in the air; decomposition begins at c. 115° with evolution of NO; at c. 180° S, (NH₄)₂SO₄, NH₄NO₂, &c., sublime; heated in air H₂O, NO, N, SO₂, are evolved, and the residue consists of FeS, Fe₂O₃, Fe₂O₄, and K₂SO₄; strong mineral acids evolve H₂S. Various metallic salts form metallic sulphides and NO, while Fe salts remain in solution; heated with alkali, crystalline Fe₂O₃ is ppd., NO evolved, and ferrinitrososulphide KFe(NO)₂S₂ is formed (Pavel, *loc. cit.*). KFe(NO)₂S₂ is soluble in about 2 parts hot water, slightly sol. in cold water, very sol. with decomposition (Pavel, B.

12, 1410) in alcohol or ether; the salt is ppd. by NH₄Aq or KOHAq. The salts of this series do not react with K₂FeCy₄.

The following salts of this series have been isolated: NH₄X, BaX₂, CaX₂ (the most stable salt of the series), CaX₂, FeX₂, LiX, MgX₂, RbX₂, TLX (X = Fe(NO)₂S₂). The Na salt is formed similarly to the K salt; also by the reaction of Na₂CS₂ with NaNO₂, the compound Fe₂S(NO)₂CS₂, said by Löw (C. C. 1865. 948) to be formed in this reaction does not exist according to Pavel (B. 15, 2603). For other reactions of the salts of the series v. Pavel, B. 15, 2604.

Ferrinitrososulphydic acid HFe(NO)₂S₂ seems to be obtained by adding a slight excess of dilute H₂SO₄ Aq to a dilute solution of the Na salt; it is insol. in water, alcohol, and ether; sol. in OHCl, or CS₂. The acid has not been obtained pure (P., *loc. cit.*).

Series II. Ferronitrososulphides MFe(NO)₂S. These salts are formed by the action of dilute alkali solutions on the salts of Series I; in these reactions NO is evolved and Fe₂O₃ ppd., but NH₄ is not evolved except from the salt NH₄Fe(NO)₂S₂. The salts of Series II. are very unstable; they easily pass into Series I.; the Cs salt is the most unstable of all; these salts are insol. in ether (except the Fe salt), CS₂, and CHCl₃; they decompose in the air with separation of S and Fe₂O₃, and evolution of a little H₂S. The solutions then have an alkaline reaction, and contain salts of Series I. along with alkaline nitrite and thiosulphate. If CO₂ is passed into a solution of K₂FeCy₄ and the K salt of Series II. is then added, NO is evolved, S and Prussian blue are ppd., and the filtrate contains K₂FeCy₄ and some KNO₂.

Potassium ferronitrososulphide

KFe(NO)₂S.2H₂O is obtained by warming KFe(NO)₂S₂ on the water-bath with dilute KOHAq, washing, and drying in *vacuo* over H₂SO₄ and CaO in the dark; it is very unstable, and can be obtained approximately pure only with difficulty (P., B. 15, 2606). By warming an alcoholic solution of KFe(NO)₂S with considerable excess of EtI, quickly distilling, washing the residue first with water and then with aqueous alcohol, and crystallising from benzene, ethyl ferronitrososulphide (C₂H₅)Fe(NO)₂S is obtained in black, lustrous, monoclinic crystals (P., *loc. cit.*). For a discussion of the probable constitution of these nitrososulphides and a comparison of them with the nitroprussides v. Pavel, B. 15, 2613.

Iron oxides of. Three oxides of iron have been isolated, FeO, Fe₂O₃, and Fe₂O₄. The molecular weight of none is known with certainty, as none has been gasified. FeO and Fe₂O₃ are basic oxides; they produce salts by reactions with acids; of the forms FeX₂ and FeX₃, X = Cl, NO₂, SO₂, PO₂, &c.; Fe₂O₃ also combines with some

more positive metallic oxides to form compounds Fe₂O₃.xM^{II}O, which are usually called *ferrites* (v. vol. ii. p. 547). Fe₂O₃ reacts with acids to form both ferrous and ferric salts, FeX₂ and FeX₃; according to Lefort a few salts corresponding with Fe₂O₄ are known, e.g. Fe₂Cl₄, Fe₂(SO₄)₂.28O.15H₂O (v. *Ferroso-ferric oxide*, p. 61). Besides the ferrites a series of *ferrates* is known (v. vol. ii. p. 548); these salts are of

the form $M'FeO$; they may be regarded as salts of the hypothetical ferric acid H_2FeO_4 ; the anhydride of this acid would be FeO , this oxide of iron has not been isolated, but the corresponding oxide of Mn, MnO , is known. All the oxides of Fe form hydrates (v. *Iron, hydrated oxides of*, p. 57). FeO very readily and rapidly absorbs O and changes to Fe_2O_3 ; at a very high temperature Fe_2O_3 parts with O, and is reduced to Fe_3O_4 .

Ferrous oxide. (*Protoxide of iron*.) FeO . This oxide cannot be obtained free from Fe_2O_3 by ppn. from ferrous salts and dehydrating the pp.

Preparation.—1. Pure Fe_3O_4 is heated to 800° in a stream of pure H (Waackroder a. Stromeyer, *Ar. Ph.* 26, 27).—2. By heating ferrous oxalate out of contact with air (Liebig, *A.* 95, 116; Moissan, *A. Ch.* [5] 21, 194).—3. By heating Fe_2O_3 for 20 minutes to $c. 500^\circ$ in H or CO, or in CO at 440° for 6 hours (Moissan, *l.c.*).—4. By heating Fe in CO_2 to $c. 1000^\circ$ (Moissan, *l.c.*).—5. By adding ferrous oxalate to boiling $KOHAq$ (Böttger, *J. pr.* 76, 239).

Properties and Reactions.—An ivory-black powder. According to Moissan (*l.c.*) FeO obtained by heating ferrous oxalate, or reducing Fe_2O_3 in CO at 500° , is pyrophoric, burns to Fe_3O_4 , and decomposes water at ordinary temperatures; while the FeO obtained by heating Fe in CO_2 at $c. 1000^\circ$ is non-pyrophoric, burns to Fe_3O_4 , and does not decompose water at 100° . Siewert (*J.* 1864, 266) says that pyrophoric FeO , produced by reduction of Fe_2O_3 in H, becomes non-pyrophoric by remaining in an atmosphere of H for 12 hours after cooling. FeO is readily oxidised to Fe_2O_3 (cf. Moissan, *supra*). It dissolves in acids to form ferrous salts FeX_2 , $X = Cl$,

NO_3 , SO_4 , &c.

Combinations.—The compound $FeO.Al_2O_3$ occurs native as *hercynite*, and $FeO.Cr_2O_3$ as *chrome-ironstone*; magnetic oxide of iron may be regarded as $FeO.Fe_2O_3$. The hydrate $FeO.H_2O$ has been isolated (v. *Hydrate of ferrous oxide*, p. 57).

Ferroso-ferric oxide. (*Black or magnetic oxide of iron*.) Fe_3O_4 . This oxide occurs native in large quantities as *magnetite*. According to Spring (*Bl.* [2] 50, 215) it is produced on the surface of iron which has been subjected to great pressure; the formation of a film of this oxide on iron rails is the reason why the surfaces of the rails of railroads do not rust (Spring, *l.c.*). When iron is strongly heated in air a film (*hammer-scale*) is produced consisting of Fe_3O_4 , mixed with, or combined with, Fe_2O_3 ; the outer layer of this film contains a large quantity of Fe_2O_3 , the inner layer, which is blackish-grey and magnetic, is approximately $6FeO.Fe_2O_3$ (Mosander, *P.* 6, 85; cf. Berthier, *A. Ch.* [2] 27, 19; Beaujeu a. Mène, *C. R.* 61, 1185; Maumené, *Bl.* 16, 25; Volcker, *W. A. B.* 86, 193; Glasen, *A.* 62, 89). S.G. 5.458 (Playfair a. Joule, *C. S. Mem.* 3, 81); 5.8 at 16.5° (Herapath, *P. M.* 64, 321). S.G. of *magnetite* 5.1 to 5.18 (Kopp; Rammelsberg). According to Moissan (*A. Ch.* [5] 21, 228) two varieties of Fe_3O_4 exist, one having S.G. 4.86 obtained by reducing Fe_2O_3 at 500° , the other having S.G. 5.19 obtained by reducing Fe_2O_3 at a higher

temperature. Berthelot (*A. Ch.* [5] 23, 118) describes two varieties, one with S.G. 4.86 obtained by heating $FeCO_3$ to 550° , the other with S.G. 5.5-5.9 obtained by highly heating the first in N. *Magnetite* crystallises in regular octahedra, isomorphous with Mn_3O_4 (Rammelsberg). C.E. 000029 (Kopp). S.H. $24^\circ-99^\circ$ 16779 (Regnault, *A. Ch.* [3] 1, 129). P.F. $[Fe_3O_4] = 26,900$; $[FeO, Fe_2O_3] = 8,800$ (Berthelot, *A. Ch.* [5] 23, 118).

Preparation.—1. By heating $FeCO_3$ to $c. 350^\circ$ in a current of CO_2 (Berthelot, *A. Ch.* [5] 23, 118).—2. By heating $FeCl_2.2NH_4Cl$ in air (Hauer, *W. A. B.* 13, 456).—3. By heating FeO in a gentle stream of HCl (Deville, *C. R.* 53, 199).—4. By melting ferric phosphate with 3.4 pts. Na_2SO_4 (Debray, *C. R.* 52, 935).—5. By melting $CaCl_2$ with ferrous sulphate in a closed crucible (Kuhlmann, *C. R.* 52, 1283).—6. By the action of FeK_3 on boric acid at a high temperature in absence of air (Deville a. Caron, *A.* 108, 56).—7. By heating $FeCl_2$ with excess of Na_2CO_3 to low redness and washing with water (Liebig a. Wöhler, *P.* 21, 582).—8. By heating Fe in steam. 9. By long-continued heating Fe_2O_3 to white heat (Sidot, *C. R.* 69, 201).—10. By reducing Fe_2O_3 in CO at 350° for about an hour (Moissan, *A. Ch.* [5] 21, 223; cf. Birnie, *R. T. C.* 2, 273; Ackermann a. Särnström, *B.* 16, 783).—11. By dehydrating $Fe_2O_3.xH_2O$ at as low a temperature as possible (v. *Hydrates of ferroso-ferric oxide*, p. 57).

Properties and Reactions.—A black, magnetic powder; the crystals obtained by methods 4-7 (*supra*) are black octahedra. According to Moissan (*A. Ch.* [5] 21, 223) and Berthelot (*A. Ch.* [5] 23, 118), Fe_3O_4 obtained by heating $FeCO_3$ in CO_2 at 350° , or by reducing Fe_2O_3 by CO at 350° , or by heating reduced Fe in H saturated with H_2O , or in CO_2 at 440° , has a lower S.G. than Fe_3O_4 produced by reductions at higher temperatures, or by strongly heating the first variety in N; the first variety is said to be easily soluble in conc. HNO_3 and to give Fe_2O_3 when heated on Pt foil; the second variety is described as almost unacted on by boiling conc. HNO_3 and as unchanged to Fe_2O_3 by heat. Fe_3O_4 is reduced to Fe by heating with C, or by strongly heating in H. With a little $HClAq$ it gives $FeCl_2Aq$ and Fe_2O_3 ; with more $HClAq$ it gives a solution showing the reactions of both ferrous and ferric chloride. According to Lefort (*C. R.* 69, 179) Fe_2Cl_6 is obtained by cooling a solution of $Fe_2O_3.xH_2O$ in excess of conc. $HClAq$ and evaporating *in vacuo* over H_2SO_4 (v. *Ferroso-ferric chloride*, p. 56). Lefort (*l.c.*) also describes a ferroso-ferric sulphate— $Fe_2O_3.6SO_4.16H_2O$ —obtained by evaporating over H_2SO_4 solutions of Fe_2O_3 in H_2SO_4 ; he says that arsenates and phosphates of Fe_2O_3 also exist; the solutions of these salts are decomposed to a mixture of ferrous and ferric salts by warming to $60^\circ-70^\circ$ (for hydrates of Fe_2O_3 , v. *Hydrates of ferroso-ferric oxide*, p. 57).

Ferric oxide. (*Peroxide, sesquioxide, or brown oxide of iron*.) Fe_2O_3 . Occurs native in large quantities widely distributed as *red hematite*, *specular iron ore*, and *marissite*. S.G. natives 5.2 to 5.28 (Rammelsberg; Kopp); calcined, 5.186 (Playfair a. Joule, *C. S. Mem.* 3, 80); ppn. 5.959 at 16.5° (Herapath, *P. M.* 64, 321). S.H.

15°-08°-16695 (Begnault, *A. Ch.* [3] 1, 129). C.E. 00004 (Kopp). Crystallises in hexagonal forms, $a:c = 1:1.36537$ (Rammelsberg).

Preparation.—1. By ppg. a ferric salt by NH_4Aq , thoroughly washing, and strongly heating the pp.—2. By strongly heating ferrous oxalate in air; Vogel (*J. pr.* 63, 187) says this method gives a very pure product.—3. By heating ferrous carbonate in air.—4. By strongly heating ferrous sulphate in air; the product seems always to contain a little basic sulphate unless the temperature is kept very high for a long time.

The oxide is obtained in crystals by the following methods:—5. By heating a mixture of equal parts ferrous sulphate and NaCl , and washing with water; the temperature must not be too high, else some Fe_2O_3 is produced.—6. By heating Fe_2O_3 in a slow stream of HCl gas (Deville, *C. R.* 52, 1364); in a rapid current of HCl , FeCl_3 is produced.—7. By melting Fe_2O_3 with CaCl_2 (Kuhlmann, *C. R.* 52, 1283).—8. By the action of FeCl_3 vapour on strongly-heated lime (Daubré, *C. R.* 49, 143).—9. By melting Fe_2O_3 with borax and treating the fused mass with warm dilute HClAq (Hauer, *W. A. B.* 13, 456).

Properties.—A reddish-brown, very hard, nonmagnetic powder; extremely hygroscopic; slightly volatile at c. 3000° (Elsner, *J. pr.* 99, 257). According to Malaguti a magnetic variety of Fe_2O_3 exists (*A. Ch.* [3] 69, 214; cf. Lallemand, *A. Ch.* [8] 69, 233; Lawrence Smith, *B.* 8, 183).

Reactions.—1. Heated to a very high temperature Fe_2O_3 is partially deoxidised to Fe_3O_4 (Sidot, *C. R.* 69, 201).—2. Reduced by heating in hydrogen; according to Moissan (*C. R.* 74, 1296) Fe_2O_3 (prepared from ferrous oxalate) is reduced to Fe_3O_4 by heating to 350° for an hour in H_2 , reduced to FeO by heating to 500° for 20 minutes in H_2 , and to Fe when heated in H_2 at 700° (cf. Siewert, *J.* 1864, 265). Wright a. Luff (*C. J.* 35, 1) found that the temperature at which reduction of Fe_2O_3 by H begins varies from 195° to 260° according to the physical state of the Fe_2O_3 used.—3. Reduced by heating in carbon monoxide; to Fe_3O_4 at 350°, to FeO at 500°, and to Fe at 700°-800° (M., L.; cf. Gruner, *C. R.* 73, 28). Temperature at which reduction begins varies from 90° to 220° according to physical state of Fe_2O_3 used (W. a. L., L.).—4. Reduced by heating with carbon to Fe_3O_4 , and then to Fe which combines with part of the C (v. *Iron, carbides of*, p. 58). *Reduction begins at 430°-450° (W. a. L., L.). According to Parry (*C. N.* 27, 818) reduction of Fe_2O_3 by C in a vacuum begins at above 400°; at 1200° c. $\frac{2}{3}$ of the oxide is reduced.—5. Reduced to FeO by heating in a mixture of equal volumes of carbon monoxide and dioxide (Debray, *C. R.* 45, 1018).—6. A mixture of carbon dioxide and cyanogen (6 vols. : 1 vol.) partially reduces Fe_2O_3 to Fe at c. 600°-700° (Bell, *J.* 1874, 266).—7. Heated in ammonia Fe_2N_3 is produced (v. *Iron, nitrides of*, p. 59). 8. Chlorine forms FeCl_3 slowly at full red-heat (Weber, *P.* 112, 619).—9. Heated with sulphur SO , and FeS are produced (Brescius, *D. P. J.* 192, 125).—10. Heated strongly in a rapid stream of hydrogen chloride FeCl_3 and H_2O are formed (Deville, *C. R.* 52, 1264).—11. Sulphurated hydrogen does not act on dry Fe_2O_3 ; with

moist Fe_2O_3 , ($\text{H}_2\text{O}, x\text{H}_2\text{O}$) FeS , S , and H_2O are formed (Wright, *C. J.* 42, 156; Brescius, *D. P. J.* 192, 125).—12. Phosphoric chloride produces FeCl_3 , which then combines with part of the PCl_5 , forming $\text{FeCl}_2\text{PCl}_4$ (Weber, *J. pr.* 76, 410).—13. Fe_2O_3 is slowly dissolved by acids, the more slowly the denser the specimen of Fe_2O_3 ; most easily dissolved by 16 times its weight of a boiling mixture of 8 pts. H_2SO_4 and 8 pts. H_2O (Mitscherlich, *J. pr.* 81, 108). After strongly heating with alkalis, alkaline carbonates, or acid sulphates, Fe_2O_3 is readily dissolved by acids.—14. Fe_2O_3 readily parts with O when heated with oxidisable organic compounds, on exposure to air O is again taken up (Robin, *C. R.* 49, 500; Gräber, *A.* 111, 134). Moist Fe_2O_3 , ($\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$) in presence of ordinary air serves as an oxidiser of various vegetable matters, e.g. wood (Kuhlmann, *D. P. J.* 155, 81; cf. P. Thénard, *C. R.* 49, 249).

Combinations.—1. Fe_2O_3 is extremely hygroscopic; it forms several hydrates by combining with water. For conditions of formation, composition, and properties v. *Hydrates of ferric oxide*, p. 57.—2. With some more positive metallic oxides to form ferrites (q.v. in vol. ii. p. 547).

HYPOTHETICAL FERRIC ANHYDRIDE. ($?\text{FeO}$.) This oxide has not been isolated, but a number of salts are known, which are best regarded as derived from the hypothetical acid H_2FeO_4 , of which FeO would be the anhydride. These salts are described under the heading *FERRATES* (vol. ii. p. 546). In addition to the descriptions there given it is to be noted that when air is blown into hot conc. NaOHAq containing c. 84 p.c. NaOH , a perceptible quantity of Fe is dissolved to form a colourless liquid, from which $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$ slowly separates (Zirnitz, *Chem. Zeitung*, 12, 355); possibly the solution contains a ferrate of Na , or, according to the suggestion of Z., a perferate NaFeO_4 (?).

Iron, oxybromides of. Oxybromides of Fe are said to be formed by evaporating FeBr_3Aq , and by the action of $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$ on FeBr_3Aq or HBrAq (Ordway, *J. pr.* 76, 19; Béchamp, *A. Ch.* [3] 57, 296; Scheufelen, *A.* 231, 157).

Iron, oxychlorides of. The oxychlorides of Fe are numerous and of complex composition; they belong to the form $x\text{FeCl}_y, y\text{Fe}_2\text{O}_3, z\text{H}_2\text{O}$. They are divided into two classes, those which are soluble in water, and those which are insoluble.

Soluble oxychlorides. Prepared by digesting freshly ppd. $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$ in FeCl_3Aq ; also by digesting excess of $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$ in HClAq . By the former method Ordway obtained $2\text{FeCl}_2, 23\text{Fe}_2\text{O}_3$ (*J. pr.* 76, 19). By the second method Béchamp (*A. Ch.* [3] 51, 296) obtained liquids containing FeCl_3 and Fe_2O_3 , in ratio 2.5, 1.3, 1.4, and 1.5. All these solutions evaporated at c. 40° give residues soluble in water; solutions containing more Fe_2O_3 than the foregoing (up to 10 Fe_2O_3) give residues on evaporation which are insol. in water. Solutions of soluble oxychlorides are not decomposed by dilution or heating, but addition of various acids and salts causes ppn. of $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$, mixed with oxychlorides, which are soluble in water. From solutions of soluble oxychlorides NH_4Aq ppt. $\text{Fe}_2\text{O}_3, x\text{H}_2\text{O}$ free from chloride, whereas the pp. obtained from the insol. oxychlorides contains chloride,

Insoluble oxychlorides. Prepared by oxidation of $\text{FeCl}_2\text{Aq.}$ by exposure to air or by HNO_3 in presence of a little HCl (Béchamp, l.c.). To saturated $\text{FeCl}_2\text{Aq.}$ HCl is added in less proportion than 8HCl to FeCl_2 ; the solution is heated to 100° , and $\text{HNO}_3\text{Aq.}$ is gradually added; a violent reaction occurs, the nearly black liquid becomes yellow, and oxychlorides separate which are insol. in water. The composition of these oxychlorides varies according to the temperature and the proportion of HCl used. Insol. oxychlorides are also formed by adding alkali to $\text{FeCl}_2\text{Aq.}$ in quantity insufficient for complete pptn. These oxychlorides vary in colour from yellow to brown; they are slowly soluble in HClAq. ; when heated they lose H_2O and HCl .

Iron, oxyfluoride of. By adding $\text{NH}_4\text{Aq.}$ to a solution of FeF_3 , a yellow salt of the composition $2\text{FeF}_3 \cdot 3\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$ is obtained (Deville, A. Ch. [3] 49, 85).

Iron, oxysulphide of. According to Rammeisberg (P. 121, 339) the product obtained by heating Fe_2O_3 in H_2S gas to near redness is $8\text{Fe}_2\text{S}_3 \cdot \text{Fe}_2\text{O}_3$.

Iron, reduced. *Ferrum redactum.* Very finely divided Fe is obtained by reducing Fe_2O_3 in a stream of pure H . Reduced iron is very readily oxidised; commercial specimens generally contain 40 p.c. or more of oxide.

Iron, phosphides* of. Meyer in 1780, and Bergmann somewhat later, obtained a phosphide of Fe ; supposing it to be a new metal they called it *Hydrosiderum* (Berl. Ges. d. naturforsch. Freunde [1781] 2, 334; Bergmann's *Opusc.* 3, 109). Several Fe phosphides have been described. According to Freese (P. 132, 225) only three exist, Fe_3P , FeP , and Fe_2P . They are non-magnetic and almost infusible; unchanged by cold HClAq. slowly acted on by boiling HClAq. giving $\frac{1}{2}$ of their P as phosphoric acid and $\frac{1}{2}$ as PH_3 ; oxidised at ordinary temperature by HNO_3 and *aqua regia*.

Fe_3P . By heating FeS in PH_3 gas (H. Rose, P. 6, 212; 24, 333); also by heating reduced Fe or FeCl in PH_3 (Freese, l.c.). A blue-grey powder, S.G. 5.04; loses P by heating in H or CO , probably forming FeP .

FeP . By heating FeS in PH_3 for a long time (Freese, l.c.); also by passing a mixture of H and P vapour over strongly heated Fe_2O_3 , and by the action of PH_3 on FeCl (H. Rose, l.c.). A black crystalline mass; not acted on by HNO_3 or HClAq. nor by I .

Fe_2P . 7 parts dry FePO_4 with 1 part lamp-black are covered with a layer of NaCl and heated to whiteness, and the fused mass is treated with HClAq. ; Fe_2P remains as a grey crystalline solid; S.G. 5.74; unchanged by heating in H , CO , or CO_2 (Freese, l.c.).

The following phosphides have been described in addition to those mentioned; according to Freese they are not definite compounds:— Fe_2P (Hoesel, A. 100, 99); Fe_2P_2 (Schenk, C. J. [2] 11, 826); Fe_2P_3 (Struve, *pr.* 79, 321); FeP (Sidot, C. R. 74, 1425).

Iron, salts of. Two series of Fe salts, obtained by replacing H of acids by Fe , are known; ferrous salts FeX , and ferric salts FeX_3 ($\text{X} = \text{Cl}$, SO_4 , NO_3 , CO_3 , PO_4 , &c., &c.). The ferric

salts are the more stable; as a class ferrous salts are readily oxidised to FeX_3 . Both series contain many well-marked and very definite compounds. Lefort (C. R. 69, 179) asserts the existence of a few salts, e.g. chloride, sulphate, phosphate, corresponding to Fe_2O_3 (v. *Ferroso-ferric oxide*, p. 61). Ferrous salts are usually obtained by dissolving Fe in various acids, or in the cases of the insol. salts by double decomposition from FeSO_4 ; they are for the most part sol. in water; a few basic ferrous salts are known, but the greater number are normal salts. Many double ferrous salts, especially with the alkali sulphates, have been isolated; many ferrous salts are isomorphous with the corresponding salts of Co , Ni , Mn , Zn , and Mg . A double ferrous-aluminium sulphate, $\text{FeSO}_4 \cdot \text{Al}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$, is said to exist and to be isomorphous with the alums. Ferric salts are generally prepared by dissolving $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in the different acids; many basic, and numerous double, ferric salts are known; the double salt $(\text{NH}_4)_2\text{SO}_4 \cdot \text{Fe}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ belongs to the class of alums. The ferric salts are generally analogous to the persalts of Al , Cr , Co , Ni , and Mn (cf. *IRON GROUP OF ELEMENTS*). The following list comprises the more important salts of Fe derived from oxyacids; for details v. CARBONATES, NITRATES, SULPHATES, &c.: *antimonates*, *arsenates* and *-ites*, *borates*, *bromates*, *carbonates*, *chlorates*, *chromates*, *hypophosphites*, *iodates*, *molybdates*, *niobates*, *nitrites*, *perchlorates*, *periodates*, *phosphates* and *-ites*, *selenates* and *-ites*, *silicates*, *sulphates* and *-ites*, *tantalates*, *tellurates* and *-ites*, *thiosulphates*, *titmates*, *tungstates*, *vanadates*.

Iron, selenides of. Selenides of Fe seem to be obtained (1) by passing Se vapour over strongly heated Fe ; (2) by heating the product obtained in (1) with Se (Berzelius); (3) by method (2) covering the mass with borax, Little (A. 112, 211) obtained Fe_2Se , thus, S.G. 6.38; (4) by ppg. Fe salts by H_2Se (Reeb, J. Ph. [4] 9, 173). By heating Fe filings with Se to redness Divers a. Shimidzu (C. J. 47, 441) obtained FeSe , resembling FeS in appearance; with acids yields H_2Se .

Iron, selenocyanides of. None has been isolated; Crookes (C. J. 4, 12) mentions various reactions which do not yield a definite salt.

Iron, silicide of. It is doubtful whether any definite compound has been isolated. Silicides are apparently formed (1) by heating Fe with Si (Deville a. Caron, C. R. 45, 163); (2) by the action of molten Fe on silicates. Hahn (A. 129, 57) obtained a body approximately Fe_3Si by fusing 60 parts Na_2SiF_6 , 20 parts Na , 60 parts Zn , and 22 parts steel, under NaCl . Other bodies, approximately Fe_2Si and Fe_3Si_2 , are described by Deville a. Caron (l.c.) and Hahn (l.c.; cf. Bous-singault, A. Ch. [3] 16, 15).

Iron, silicofluoride of, FeSiF_3 ; v. Ferrous fluoride, p. 56.

Iron, sulphocyanides of, v. vol. ii. p. 350.

Iron, sulphides of. Four are known, FeS , Fe_2S_3 , Fe_3S_4 , and FeS_2 ; a subsulphide, Fe_2S , also probably exists. According to Gautier a. Hallopeau (C. R. 108, 806) a yellow-grey lustrous body, Fe_2S , is formed by heating Fe in CS_2 for several hours at 1800° – 1400° .

IRON SUBSULPHIDES Fe_2S . Said by Arrvedson (P. 1, 82) to be produced, as a greyish-black powder, by heating dry FeSO_4 in H .

Ferrous sulphide FeS . (*Iron monosulphide* or *protosulphide*.) Occurs sometimes in meteorites; also in combination with NiS.

Formation.—1. By heating FeS_2 with Fe until the mass is thoroughly molten.—2. By reducing FeS_2 in H.—3. By the reduction of Fe_2O_3 or ferric salts by decomposing organic matter in presence of sulphate (Chevreul, *C. R.* 43, 218). 4. By gently heating a mixture 1 part S with 1½ parts Fe filings moistened with water; if a considerable quantity of such a mixture is made into a paste with water and covered with earth, the mass after a time becomes red hot and evolves much steam which throws up the earth with some violence.—5. By strongly heating Fe_2O_3 or a ferric salt in H_2S (Sidot, *C. R.* 66, 1257; cf. Carnot, *Bl.* [2] 82, 162).—6. By heating a mixture of Fe_2O_3 and S in H (Rose, *P.* 110, 120).—7. By heating to redness a mixture of Fe_2O_3 and excess of $\text{Na}_2\text{S}_2\text{O}_3$ (Gibbs, *Am. S.* [2] 87, 846).

Preparation.—1. A mixture of 3 parts Fe filings and 2 parts S is strongly heated in a covered crucible until the whole mass is thoroughly melted; if the temperature is not high enough some Fe remains and some Fe_2S_3 is formed.—2. A white-hot rod of iron is plunged into molten S; the FeS formed flows off; the operation is repeated as long as any S remains (Gahn; Rammelsberg, *B.* 1862, 681).—3. By ppg. a ferrous salt by an alkali sulphide, preferably NH_4 sulphide.

Properties.— FeS prepared in the dry way is yellow-brown, lustrous, metal-like solid, crystallising in hexagonal prisms, S.G. 4.69. Non-magnetic; not changed by heating out of contact with air or in H. FeS prepared in the wet way is an amorphous, greenish-black powder, which on gently heating in air is partly changed to Fe_2O_3 ; it is slightly soluble in water. By ppg. FeS in a very dilute solution, and then dialysing away the other products of the reaction, Winsinger (*Bl.* [2] 49, 452) obtained a very dilute solution of colloidal FeS ; the solution was greenish-brown, oxidised and coagulated very readily.

Reactions.— FeS prepared in dry way: 1. Heated in hydrogen, or out of contact with air, is unchanged.—2. Heated in steam evolves H and H_2S , and leaves a black magnetic mass containing Fe_2O_3 (Regnault, *A. Ch.* [3] 62, 379).—3. Heated strongly in air forms Fe_2O_3 and SO_2 .—4. With dilute hydrochloric or sulphuric acid evolves H_2S , and forms FeCl_2 or FeSO_4 .—5. Oxidised by nitric acid.—6. Heated with chlorine from S_2Cl_2 and FeCl_3 .

FeS prepared in the wet way: 7. Oxidises in air at ordinary temperature, forming $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, S, and a little basic Fe sulphate (Wagner, *D. P.* 192, 131).—8. Slightly soluble in water; ppgd. by NH_4HS .—9. Soluble in sulphurous acid solution, also in potassium cyanide solution (Goussier, *C. R.* 75, 1276).—10. Slightly soluble in solutions of alkaline sulphides.—11. Very easily decomposed by acids, with evolution of H_2S .

Ferroso-ferric sulphide Fe_2S_3 . (*Magnetic sulphide of iron*.) Occurs native as magnetic pyrites in hexagonal crystals, S.G. 4.51 to 4.64; the composition may be expressed as $x\text{FeS} \cdot \text{Fe}_2\text{S}_3$, x is very seldom = 1, generally = 5 and 6. The first product of the action of H_2S on strongly

heated Fe_2O_3 is Fe_2S_3 , but this decomposes to FeS (Sidot, *C. R.* 66, 1257).

Ferric sulphide Fe_2S_3 . (*Sesquisulphide of iron*.) By heating a mixture of powdered FeS and S to redness, or by passing H_2S over Fe_2O_3 at 100° (Berzelius, *P.* 7, 893). A greenish-yellow mass; magnetic according to Proust (*Scher. J.* 10, 54); non-magnetic according to Berzelius (*l.c.*). When heated, gives Fe_2S_3 ; when moist soon changes to a mixture of S and Fe_2O_3 ; decomposed by dilute acids forming ferrous salts, H_2S , and $\text{H}_2\text{S}_2\text{S}_8$.

Combines with Fe_2O_3 when heated with it. The product of the reaction of H_2S on Fe_2O_3 at somewhat above 100° is $\text{Fe}_2\text{O}_3 \cdot 3\text{Fe}_2\text{S}_3$, according to Rammelsberg (*P.* 121, 837). Combines with CuS to form $\text{CuS} \cdot \text{Fe}_2\text{S}_3$; also with K_2S , Na_2S , Ag_2S . These compounds may be regarded as *sulphoferrites*; they belong to the form $\text{M}_2\text{Fe}_2\text{S}_3$, and are produced by fusing 1 part Fe filings with 5-6 parts S and 5-6 parts alkaline carbonate; the Ag salt is obtained by adding AgNO_3 to the K salt suspended in water (v. Schneider, *P.* 136, 460; Preis, *J. pr.* 107, 10). Fe_2S_3 is said to form a hydrate, $\text{Fe}_2\text{S}_3 \cdot 3\text{H}_2\text{O}$, a greenish-black pp. obtained by adding NH_4HSaQ to a ferric solution containing an oxidiser such as Cl_2 or a hypochlorite (Phipson, *C. N.* 80, 139).

IRON DISULPHIDE FeS_2 . (*Iron pyrites*.)

Occurrence.—In large quantities; in regular crystals as *yellow pyrites*, and in rhombic crystals as *white pyrites*.

Formation.—1. By slowly heating a mixture of Fe_2O_3 , S, and NH_4Cl (Wöhler, *P.* 37, 288).—2. By the action of CS_2 on Fe_2O_3 (Schlagdenhauffen, *J. Ph.* [3] 34, 175).—3. By heating Fe, or Fe_2O_3 , with SO_2 in a sealed tube to 200° (Geitner, *A.* 129, 850).—4. By passing H_2S over an oxide or chloride of Fe at a temperature above 100° but below redness.—5. By the action of organic matter on water containing Fe and sulphates in solution.—6. Glatzel (*B.* 23, 37) obtained crystals of FeS_2 by strongly heating FeCl_3 with P_2S_5 .

Preparation.—1. An intimate mixture of 2 parts FeS and 1 part S, or of 1 part Fe with 1½ parts S, is heated in a retort to a temperature somewhat under red heat, and the product is treated with dilute HClAq (Berzelius); below 100° the chief product is Fe_2S_3 , and at red heat Fe_2S_3 is formed.—2. By mixing an alkaline persulphide solution with FeCl_2Aq at 180° or with FeSO_4Aq at 165° (Senarmont, *A. Ch.* [3] 80, 129).

• **Properties.**—A bulky dark-yellow powder, or crystallised in small brass-yellow cubes and octahedra. Not magnetic. The rhombic form of FeS_2 oxidises in moist air forming Fe_2SO_4 , S, and H_2SO_4 .

• **Reactions.**—1. White iron pyrites, finely-divided yellow pyrites, or FeS_2 prepared in the wet way, oxidise in air, forming chiefly Fe_2SO_4 , and at higher temperatures SO_2 and Fe_2O_3 .—2. Calcined with carbon, gives CS_2 .—3. Not acted on by *nitric acid*; but decomposed by conc. hydrochloric acid, giving H_2S and S.—4. Oxidised by heating with conc. nitric acid.

Iron, telluride of. Produced by reducing ferrous tellurite in H (Berzelius).

R. M. P. M.

IRON ALUMS

K_2 [or $(\text{NH}_4)_2$] $\text{SO}_4 \cdot \text{Fe}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$, v. ALUMS, vol. i. p. 148; and SULPHATES. M. M. P. M.

IRON GROUP OF ELEMENTS.

65

IRON GROUP OF ELEMENTS. The four elements, IRON, NICKEL, COBALT, and MANGANESE, are more or less closely connected. Fe, Ni, and Co occur in meteorites, some of which also contain minute quantities of Mn. The chief ores of Fe and Mn are oxides, carbonates, and sulphides, of Ni and Co sulphides and arsenides. Fe has been known and used for ages; Ni, Co, and Mn have been known from about the middle of the eighteenth century. The name *iron* is probably a form of the Sanscrit word *ayas* (= metal); the names *nickel* and *cobalt* are derived from terms used by miners in the Middle Ages to express false or spurious metals, or minerals from which no useful metals could be obtained; *manganese* is said to be a corruption from *mag-*

nesia nigra, a name long given to the mineral pyrolusite. Compounds of Fe occur in large quantities, widely distributed; compounds of Mn are not so common, nor so widely distributed; and compounds of Ni and Co occur only sparingly. Fe, Ni, Co, and Mn are obtained by reducing the oxides with charcoal at high temperatures. The metals are all hard, lustrous, fairly malleable and ductile; they crystallise in the regular system; they are more or less magnetic; they are unacted on by dry air, but oxidise slowly in moist air; they decompose steam, and react with acids to form salts. The following table presents some of the characteristic properties of the four metals:—

	MANGANESE	IRON	NICKEL	COBALT
<i>Atomic weights.</i>	55	55.9	58.6	58.8
	One compound of Mn (MnCl ₂), and two of Fe (FeCl ₂ and FeCl ₃) have been gasified; no Ni or Co compounds have been gasified; specific heats of the four metals have been directly determined. Molecular weights unknown.			
<i>Melting-points</i> (approx.)	1800°-1900°	1600°	1500°	1500°
<i>Spec. grav.</i> (approx.)	8	7.8	8.9	8.6
<i>Atom. weight.</i>	6.9	7.2	6.6	6.8
<i>Spec. grav.</i> (approx.)				
<i>Occurrence and Preparation.</i>	Occurs chiefly as MnO ₂ . Obtained by reducing the oxides by C at a high temperature; Also by reducing the chloride or fluoride by Na.	Chiefly as Fe ₂ O ₃ , Fe ₃ O ₄ , and FeCO ₃ . Obtained by reducing Fe ₂ O ₃ by C, or CO, at a high temperature; also by reducing Fe ₂ O ₃ or Fe ₃ O ₄ in H ₂ , and by electrolysis of FeSO ₄ aq.	Chiefly as NiAs and NiAsS. Obtained by reducing Ni ₂ O ₃ by C at a high temperature, or by heating in H ₂ .	Chiefly as CoAs ₂ and CoAsS. Obtained by reducing Co ₂ O ₃ by heating with C, or in H ₂ .
<i>Physical properties.</i>	Greyish - white, brittle, very hard, lustrous, magnetic. Melts above M.P. of Fe.	Lustrous, greyish-white, very tenacious; crystallises in regular cubes and octahedra; magnetic. Ordinary iron, containing from .2 to .5 p.c. C, is very hard, malleable, and fairly ductile. Fe obtained by reduction of Fe ₂ O ₃ in H ₂ below 600° is pyrophoric. By electrolysis of FeSO ₄ aq a soft, amorphous, brittle mass is obtained.	Silver-white, very tenacious, hard, ductile, malleable; magnetic up to c. 250°; crystallises in regular cubes and octahedra.	Steel-grey, lustrous, hard, very ductile at red heat and upwards; somewhat malleable; magnetic; crystallises in regular cubes and octahedra.
<i>Chemical properties.</i>	Oxidises easily in air; Mn obtained by reducing chloride by Na is said not to tarnish in ordinary air. Oxidised by heating in air. Decomposes steam; said to decompose	Unchanged in dry air; in moist air forms Fe ₂ O ₃ ·xH ₂ O; heated in air or O ₂ burns to Fe ₂ O ₃ and Fe ₃ O ₄ . Decomposes steam, forming Fe ₂ O ₃ and H ₂ . TABLE—continued.*

	MANGANESE	IRON	NICKEL	COBALT
	<p>cold water slowly. Dissolves in dilute acids; hardly acted on by cold conc. H_2SO_4. Combines directly with Cl and Br. No simple cyanide of Mn is known; but the acid H_2MnCy_2 and salts derived from it, and also salts of the hypothetical acid H_2MnCy_2, have been isolated. With acids forms two series of salts, MnX_2 and MnX_3, of which the manganous salts ($\text{X} = \text{Cl}, \text{SO}_4, \text{etc.}$) are the more stable. Besides the oxides corresponding to the salts (MnO and Mn_2O_3) other acidic oxides, MnO_2 and Mn_2O_7, have been isolated; the acid HMnO_4, and numerous salts of this acid, are known; salts of the hypothetical acid H_2MnO_4 are also numerous. Atom of Mn is divalent in the gaseous molecule MnCl_2.</p>	<p>sol. in cold conc. H_2SO_4; unacted on by cold conc. HNO_3. Combines directly with Cl, Br, and I; also with C, and probably with H and N. No simple cyanide is known, but a large number of ferro- and ferricyanides, and also the acids H_2FeCy_2 and H_2FeCy_3, have been isolated. Some ammonio-compounds are known. Reacts with acids to form two series of salts, FeX_2 and FeX_3, of which the ferric salts ($\text{X} = \text{Cl}, \text{SO}_4, \text{etc.}$) are the more stable. Ferrates, M_2FeO_4, are also known, but neither the corresponding acid nor anhydride has been isolated. Atom of Fe appears to be divalent and trivalent in gaseous molecules (FeCl_2 and FeCl_3); perhaps also tetravalent (Fe_2Cl_4 and Fe_3Cl_4).</p>	<p>cold conc. HNO_3. Combines directly with Cl, Br, and I. Probably forms a nitride by heating NiO in NH_3. NiCy_2 and many double cyanides are known, but no acids or salts corresponding with ferro-, ferri-, mangan-, and mangani-cyanides have been isolated. Some ammonio-compounds are known. With acids forms two series of salts, NiX_2 and NiX_3, of which the nickelous salts ($\text{X} = \text{Cl}, \text{SO}_4, \text{etc.}$) are much the more stable. No salts in which Ni forms part of the acidic radicle have yet been certainly isolated.</p>	<p>cold conc. HNO_3. Combines directly with Cl, Br, and I; also probably with C. CoO, is known; also the acids H_2CoCy_2 and H_2CoCy_3, and many salts derived therefrom. Very many ammonio-compounds are known. With acids forms two series of salts, CoX_2 and CoX_3, of which the cobaltous salts ($\text{X} = \text{Cl}, \text{SO}_4, \text{etc.}$) are much the more stable. By the action of molten KOH on CoO a salt is obtained in which Co seems to form part of the negative radicle.</p>

General formulae and character of compounds.—Oxides.— MO , M_2O_3 , M_2O_5 ; also MnO_2 , Mn_2O_3 , Mn_2O_7 . Sulphides.— MS , M_2S_3 , M_2S_5 , MS_2 . Haloid compounds.— MX_2 or MX_3 ; also FeX_2 or Fe_2X_3 ; ?MnCl_2 , ?MnCl_3 . Salts.— MX_2 and MX_3 , $\text{X} = \text{NO}_3, \text{PO}_4, \text{etc.}$ Salts containing M in the acidic radicle.— $\text{N}^+\text{M}^-\text{O}_4$, where $\text{M} = \text{Mn}$ or Fe ; also N^+MnO_4 (?NaFeO_4); also $\alpha\text{MO}_2\cdot\gamma\text{Fe}_2\text{O}_3$, where $\text{M} =$ decidedly positive metal. Acids.— HMnO_4 .

The oxides MO are basic. They react with acids to form salts MX_2 . MnO and FeO are readily oxidised by standing in air, FeO very rapidly. NiO and CoO , on the other hand, are obtained by heating the higher oxides in air. The oxides M_2O_3 are basic, forming salts MX_3 . In the case of Mn only a few salts corresponding to M_2O_3 are known, e.g. $\text{Mn}_2(\text{SO}_4)_3$. In the cases of Ni and Co the salts of M_2O_3 are hardly known; the oxides dissolve in cold conc. acids, probably forming salts; but on warming salts of MO are obtained. Both Fe_2O_3 and Mn_2O_3 show feebly acidic properties, as they combine with some more basic oxides, e.g. CaO , BaO , ZnO .

The oxides M_2O_5 react with acids, for the most part, as compounds of MO with M_2O_3 . Fe_2O_5 , however, is said to produce a few corresponding salts, e.g. Fe_2Cl_5 and $\text{Fe}_2(\text{SO}_4)_5$. It is doubtful whether MnO_2 form any corresponding salts; with acids it usually evolves O , and forms manganous salts MnX_2 . It combines with several more positive oxides, e.g. CaO or BaO , to form compounds $\alpha\text{M}^+\text{O}_2\cdot\gamma\text{MnO}_2$. MnO_2 and Mn_2O_7 are extremely unstable acidic oxides. The acid of Mn_2O_7 , viz. HMnO_4 or H_2MnO_7 , is known, and from it a large series of salts has been obtained. The acid of MnO_2 (H_2MnO_4) has not been isolated; but the manganates M^+MnO_4 are well-known salts. Ferrates, M^+FeO_4 , corresponding to the manganates, are known, although neither the acid H_2FeO_4 nor the anhydride FeO has been isolated.

The sulphides MS are basic; but MnS shows slightly acidic properties. MnS forms a compound with the very positive K_2S ($\text{K}_2\text{S}\cdot 3\text{MnS}$); CoS on the other hand, combines with the slightly negative As_2S_3 ($2\text{CoS}\cdot\text{As}_2\text{S}_3$). Fe_2S_3 forms compounds with Ag_2S , CuS , etc., which may be regarded as sulphoferrites.

The haloid compounds MX_2 or M_2X , are generally formed by direct union of the elements, also by dissolving the oxides MO in the haloid acids HX and evaporating. Fe is the only member of the group which certainly forms haloid compounds containing more halogen than MX_2 . There are, however, indications of the existence of $MnCl_3$ and $MnCl_4$. The haloid compounds which have been gasified are $MnCl_2$, $FeCl_2$, and $FeCl_3$. There are no indications of the existence of gaseous molecules Mn_2Cl_4 ; but the V.D.s of ferrous and ferric chlorides point to the existence of the gaseous molecules $FeCl_2$ and $FeCl_3$ at high temperatures, and Fe_2Cl_4 and Fe_3Cl_8 at lower temperatures.

The salts of the metals of the iron group belong to the series MX_2 and MX_3 , where $X = NO_3$, ClO_4 , $\frac{1}{2}SO_4$, $\frac{1}{2}CO_3$, $\frac{1}{2}PO_4$, &c. Fe forms many salts of both series; Mn forms chiefly manganous salts MnX_2 , but a few manganic salts are known, e.g. $Mn_2(SO_4)_3$; Ni forms only nickelous salts NiX_2 . The cobaltic salts are represented by a few double salts, e.g. $Co(NO_3)_2 \cdot 3KNO_3$; but the cobaltous salts are numerous. Ferrous salts are perfectly definite, but are fairly easily oxidised to ferric. Ferric and manganic sulphates form alums, $K_2SO_4 \cdot Fe_2(SO_4)_3 \cdot 24H_2O$. Many of the salts MX_2 are isomorphous with the corresponding salts of Cu, Zn, Mg, and Cd.

The only member of the series which forms acid oxides that have been isolated is Mn (*v. supra*). Permanganic acid, $HMnO_4$, has also been isolated, but no oxyacid of Fe, Ni, or Co.

The iron elements exhibit analogies with several other families of elements. Their relations with the elements of Group III., especially with Al, Ga, and In, are shown in the composition of the salts MX_3 ; in the existence of alums, e.g. $K_2SO_4 \cdot M_2(SO_4)_3 \cdot 24H_2O$, where $M = Al, Ga, In, Fe, \text{ or } Mn$; also in the existence and dissociation of the gaseous molecules Fe_2Cl_4 , Al_2Cl_6 , and Ga_2Cl_6 . The analogies shown by Ni and Co to the Al family are very slight.

The iron family is distantly connected with the halogens. This is shown in the existence of the salts $NiMO_4$, where $M = Mn$ (? Fe), Cl, or I.

The relations between the iron family and the chromium family of Group VI are fairly well marked; the MX_3 salts are similar to the CrX_3 salts; MnO_2 resembles CrO_3 in being acidic and forming salts Mn_2MnO_7 , analogous to and isomorphous with the chromates. α -Ferrates, M_2FeO_4 , are also known, although neither FeO_3 nor H_2FeO_4 has been isolated. MnO_2 is not unlike CrO_3 in some of its reactions. The sulpho-ferrites, e.g. $CuFe_2S_4$, resemble the sulpho-chromites, e.g. $ZnCr_2S_4$. The relations of Ni and Co to the Cr family are chiefly shown in the formulae of the nickelous, cobaltous, and chromous salts, MX_2 ; in the existence of many ammonio-cobalt and ammonio-chromium compounds. The formation of the cyanogen acid $H_2M_2Cy_4$ and of salts of $H_2M_2Cy_4$, where $M = Mn, Fe, Co, \text{ or } Cr$, is a point of similarity between Cr and the iron family.

The composition of the salts MX_3 is similar to that of the salts of Group II.; so far as properties go these salts most resemble those of the odd series members of Group II., Mg, Zn, and Cd; the ammonio-compounds of Co also recall

the ammonio-compounds of Hg which is an odd-series member of Group II.

There are some resemblances between Cu which belongs to Group I. and the iron elements; thus the salts MX_2 resemble in many respects the cupric salts CuX_2 ; there are many ammonio-copper compounds; numerous double cyanides of Cu exist and some of these are probably derived from a cyanogen acid $H_2Cu_2Cy_4$.

Finally some of the physical properties of the iron family resemble the properties of the two other families of Group VIII., viz. Rh, Ru, Pd, and Os, Ir, Pt.; this resemblance is carried out in the formulae of some of the salts, and in the existence, and in some cases the composition and properties, of numerous complex cyanides; these complex cyanides are indicated in the following table:—

$H_2M_2Cy_4$ and salts.	$H_2M_2Cy_4$ and salts.
$M = Mn, Fe, Co; Os, Ru$	$M = Fe, Co; Ir$
Salts of $H_2M_2Cy_4$ (acid not isolated).	
$M = Mn, Rh.$	

The acid H_2PtCy_4 and salts of this acid exist; salts of H_2PdCy_4 are known. It should be noted that Ni does not form nickelo- or nickeli-cyanides analogous to any of the complex cyanides formulated above, but only ordinary double cyanides.

The position of the iron family of elements in the classification based on the periodic law is somewhat peculiar (*v. Table on p. 204 of vol. ii.*) Mn is placed in the even series of Group VII.; the only other members of this group as yet known are the halogens. Fe, Ni, and Co form a division, or family, of Group VIII.; the other families of this group are (1) Rh, Ru, Pd, and (2) Os, Ir, Pt. The iron family should therefore, strictly, include only Fe, Ni, and Co; Mn has been included in this family because of its close relations to Fe; but because of its position in Group VII., Mn has also been included in the halogen family (*v. HALOGEN ELEMENTS, vol. ii. p. 664*). Each of the three families which together constitute Group VIII. is separated from the others by many elements; the analogies between these families cannot be very close. The iron family is preceded in order of atomic weights by a series of elements, which begins with the very positive element K and ends with the element Cr which is both metallic and non-metallic; the iron family is succeeded by series 5 which begins with the undoubtedly metallic Cu and ends with the no less undoubtedly non-metal Br. The iron family forms one of the turning-points in the swing of properties from very positive to very negative; the next similar turning-point is marked by the second family of Group VIII., Rh, Ru, Pd; and the third turning-point is marked by the last family of Group VIII., Os, Ir, Pt. Recent researches show that Co and Ni are perhaps separable each into two other elements, *v. NICKEL in this volume*. In connection with this article *v. ISAMIC ACID *v.* ISATIN.ISATANE *v.* ISATYDE.ISATIC ACID $C_6H_5(NO_2)CO_2H$.

$C_6H_5(NH_2)CO_2CO_2H$. *o*-Amido-phenyl-glyoxylic acid. Formed, as potassium salt, by boiling isatin with conc. KOHAq (Laurent, *A. Ch.* [3] 3, 871; Erdmann, *J. pr.* 24, 13). Obtained synthetically by reduction of an alkaline solution of *o*-nitro-phenyl-glyoxylic acid with ferrous sulphate (Claisen & Shadwell, *B.* 12, 353). By decomposing the lead salt with H_2S and evaporating at atmospheric temperature *in vacuo* isatic acid may be obtained as an amorphous white powder, soluble in cold water. The acidified solution deposits, after a while, crystals of isatin, which is its anhydride, and the separation may be hastened by warming. With acetone in alkaline solution isatic acid forms (Py. 3)-methyl-quinoline (Py. 1)-carboxylic acid [241°]. Its silver salt forms microscopic needles (W. Pfützinger, *J. pr.* [2] 33, 100; Beyer, *J. pr.* [2] 33, 416). Acetophenone gives, in like manner, phenyl-quinoline carboxylic acid.

Salts.—KA': faint yellow crystals, which dissolve in conc. KOHAq, forming a deep violet-red solution, turned yellow on dilution with water. Its solution gives a yellow flocculent pp. with lead acetate, and, when concentrated, it is also ppd. by $BaCl_2$.—BA'A': (at 150°): scales.—AG'A': beautiful yellow prisms, sol. water.

Acetyl derivative $C_6H_5(NHAc)CO_2CO_2H$. [160°]. Obtained from acetyl-isatin by dissolving in cold dilute NaOHAq and ppg. with dilute H_2SO_4 (Suida, *B.* 11, 586). Needles (from alcohol). Sl. sol. cold water, m. sol. alcohol, ether, and benzene. Boiling HClaq converts it into isatin. Sodium-amalgam reduces it to the acetyl derivative of *o*-oxy-*o*-amido-phenyl-acetic acid $C_6H_5(NHAc)CH(OH)CO_2H$, which forms colourless needles [142°] converted by HI into oxindole.

Chloro-isatin acid $C_6H_4Cl(NH_2)CO_2CO_2H$. From chloro-isatin by warming with KOHAq (Erdmann, *J. pr.* 19, 339; 24, 5; *A.* 33, 129; Laurent, *A. Ch.* [3] 3, 878). Not known in the free state, since, when its salts are acidified, chloro-isatin is formed.—KA': light-yellow flattened needles (from alcohol); v. sol. water.—BA'A': pale yellow needles.—BA'A', 2aq: brilliant deep-yellow laminae.—PbA', 2aq: brilliant yellow gelatinous pp., which in a few minutes changes to scarlet PbA', aq.—AG'A': light-yellow pp.; sol. boiling water.—The cupric salt is ppd. as a brownish-red powder, which changes to blood-red.

Di-chloro-isatin acid $C_6H_3Cl_2(NH_2)CO_2CO_2H$. Formed by dissolving di-chloro-isatin in hot KOHAq. Separates on addition of HCl as a yellow pp., which, even when exposed over sulphuric acid *in vacuo* in the cold, splits up into water and di-chloro-isatin. It dissolves in water forming a light-yellow solution, which becomes turbid at 60° and deposits di-chloro-isatin.—KA' aq: yellow laminae.—BA'A', 2aq: golden needles.—CuA': reddish-brown pp. changing to greenish-yellow and crimson.—AG'A': small yellowish needles (from hot water).

Bromo-isatin acid $C_6H_4Br(NH_2)CO_2CO_2H$. Formed by warming bromo-isatin with aqueous caustic potash (Gericks, *J. pr.* 95, 176, 257). The free acid splits up at once into water and bromo-

isatin.—KA': easily soluble cauliflower-like crystals.—NaA': warty crystals.—BA'A', 8aq: yellow prisms.—CuA', 2aq: red granular pp.—PbA', 2aq: yellow pp., changing to a scarlet crystalline powder.—ZnA', 2aq: brownish pp., changing to red granular powder.—AgA': light-yellow needles (from hot water).

Di-bromo-isatin acid $C_6H_3Br_2(NH_2)CO_2H$. From di-bromo-isatin and hot KOHAq (Erdmann, *J. pr.* 19, 360). The free acid is ppd. by adding HCl to a conc. solution of the K salt as a light-yellow powder, soluble in a large quantity of water. By desiccation, even at 15° *in vacuo*, it is decomposed into di-bromo-isatin and water.—KA' aq: pale yellow needles, v. sl. sol. water.

Ethyl ether EtA'. [105°]. From the silver salt and EtI (Baeyer & Oekonomides, *B.* 15, 2099). V. sol. ordinary solvents. At 110° it gives di-bromo-isatin.

Sulpho-isatin acid $C_6H_4(SO_3H)(NH_2)CO_2CO_2H$. From isatin sulphonic acid and excess of alkali (G. & A. Schlieper, *A.* 120, 12). Only known in its salts, which are converted by mineral acids into isatin sulphonic acid.—K₂A'' aq: waxy-yellow prisms, v. sol. water.—BA'' 3aq: long silky lemon-yellow needles; v. sol. boiling water, insol. alcohol.—PbA'' 1½aq: yellow needles; v. sol. water.—Ag₂A'' 1½aq: pale yellow needles, sl. sol. water.

Isomeride of isatin acid *v.* *m*-AMIDO-PHENYL-GLYOXYLIC ACID.

***p*-Methyl-isatin acid. Acetyl derivative** $C_6H_4(CH_3)(NHAc)CO_2CO_2H$. [172°]. Small white needles, soluble in alcohol and hot water, very sparingly in ether, benzene, ligroin, and CS_2 . Formed by the action of cold aqueous alkalis upon acetyl-*p*-methyl-pseudo-isatin.

Ethyl ether of the acetyl derivative $C_6H_4(CH_3)(NHAc)CO_2CO_2Et$. [79°]. White glistening plates; insol. water. Formed by boiling acetyl-*p*-methyl-pseudo-isatin with dilute alcohol (Duisberg, *B.* 18, 198).

Amide of the acetyl derivative $C_6H_4(CH_3)(NHAc)CO_2CONH_2$. [141°]. Formed by the action of alcoholic NH_3 on the acetyl derivative of methyl-*p*-isatin (Panaotovid, *J. pr.* [2] 33, 72). Trimetric prisms (from alcohol), insol. water.

ISATILIN *v.* ISATIN.ISATIMIDE *v.* ISATIN.

• ISATIN $C_6H_5(NO_2)CO_2H$ & $C_6H_5\begin{smallmatrix} \text{CO} \\ \text{<N>} \end{smallmatrix}CO_2H$

(stable form) or $C_6H_5\begin{smallmatrix} \text{CO} \\ \text{<NH>} \end{smallmatrix}CO_2H$ (transition form or pseudo-isatin. *Anhydride of isatin acid. o*-Amido-phenyl-glyoxylic lactim. [201°].

Formation.—1. Discovered simultaneously by Laurent (*A. Ch.* [3] 3, 871) and by Erdmann (*J. pr.* 24, 11) as a product of the oxidation of indigo by nitric acid (L.) or chromic acid (E.).—2. By oxidising amido-oxindole with $FeCl_3$, nitrous acid, or $CuCl_2$ (Baeyer, *B.* 11, 1228). The oxindole may be obtained from phenyl-acetic acid by nitration and reduction (Baeyer, *B.* 11, 583), and converted successively into nitroso-oxindole and amido-oxindole.—3. Prepared by boiling *o*-nitro-phenyl-propionic acid with alkalis (Baeyer, *B.* 18, 2259). The reaction possibly takes place as follows:

(Michael, *J. pr.* [2] 35, 255).—4. Together with $\text{N}_2(\text{C}_2\text{H}_5\text{CO}_2\text{H})_2$, by dissolving isatogenic ether in aqueous Na_2CO_3 (Baeyer, *B.* 15, 55).—5. From isatogenic acid by dissolving in H_2SO_4 and adding water (Baeyer, *B.* 14, 1742).—6. By oxidising carbostyryl with alkaline KMnO_4 (Friedländer a. Ostermaier, *B.* 14, 1921).—7. By boiling nitroso-(7)-oxy-carbostyryl with conc. HCl aq (Baeyer a. Hemmle, *B.* 16, 2217).—8. By heating anthroxanic acid with FeSO_4 and dilute ammonia (Schillinger a. Wleügel, *B.* 16, 2224).

Preparation.—1. Finely-powdered indigo (50g. of 65 p.c.) is made into a thin paste with boiling water, and a dilute solution of CrO_3 (30 g.) is added. The liquid is boiled till it begins to froth strongly, and is then filtered hot, when isatin separates on cooling. The yield is moderate (9 g.) (Sommaruga, *A.* 190, 369).—2. A mixture of indigo (100 pts.), boiling water (300 pts.), and nitric acid (70 pts. of S.G. 1.35) is boiled for two minutes, diluted with boiling water (2000 pts.), boiled for five minutes more and filtered. The isatin separates on cooling. It may be purified by dissolving in aqueous KOH , adding HCl as long as it forms a black or brown pp., filtering, adding more HCl to the clear yellow filtrate, and washing the red pp. of isatin (Forrer, *B.* 17, 976; Hofmann, *A.* 53, 11).

Properties.—Yellowish-red • monoclinic prisms; $a:b:c = 425:1:503$; $\beta = 85^\circ 18'$ (Bodewig, *Z. K.* 4, 65). Has no odour, but a bitter taste. Sl. sol. cold, m. sol. boiling, water, forming a reddish-yellow solution. V. e. sol. alcohol, sl. sol. ether. The alcoholic solution imparts an unpleasant odour to the skin.

Reactions.—1. It is not attacked by dilute nitric acid, but a stronger acid forms nitro-o-oxybenzoic acid, while conc. HNO_3 forms oxalic acid.—2. Nitrous acid, acting upon isatin suspended in water, forms nitro-o-oxybenzoic acid (Hofmann, *A.* 115, 280); while, in presence of alcohol, nitrous acid forms benzoic acid (Baeyer, *a.* Knop, *A.* 140, 4).—3. Chromic acid in presence of acetic acid forms isatoic acid

the other hand, acetyl-isatin $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \text{NACO} \end{array} \text{CO}_2\text{H}$, being a derivative of pseudo-isatin, yields acetyl-o-amido-benzoic acid $\text{C}_6\text{H}_4(\text{NHAc})\text{CO}_2\text{H}$ on similar treatment (E. v. Meyer a. J. Bellmann, *J. pr.* [2] 83, 30).—4. Chlorine and bromine form products of substitution.—5. Cold aqueous caustic potash forms a red solution, which on boiling immediately becomes yellow, and then contains potassium isatate. If the solution be concentrated by distillation, decomposition suddenly takes place, aniline and hydrogen being

given off.—6. Aqueous ammonia forms isamic acid. Alcoholic NH_3 gives a variety of products, called by Laurent imesatin, imasatin, amisatin, isatimide, and isatylim. By heating isatin with alcoholic NH_3 in sealed tubes Sommaruga (*A.* 190, 371) obtained di-imido-isatin, oxy-di-imido-isatin, and deoxy-imido-isatin.—7. Isatin combines with alkaline bisulphites.—8. SO_2 has no action.—9. H_2S gives di-thio-isatyde.—10. Sodium-amalgam reduces it to isatyde $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$, and dioxindole $\text{C}_8\text{H}_6\text{N}_2\text{O}_2$.—11. Ammonium sulphide reduces it to isatyde.—12. Zinc and dilute H_2SO_4 form isatyde.—13. Zinc-dust and a little dilute HCl form isatyde and dioxindole (Baeyer, *B.* 12, 1309).—14. Zinc-dust added to a cold solution of isatin in HOAc forms a colourless solution (? of isatin hydride) which becomes coloured again on exposure to the air, isatin being reproduced.—15. Aqueous HI (S.G. 1.4) at 100° forms isatyde. At 140° it forms a dark-green insoluble mass, whence boiling alcohol leaves a dark-grey residue, isatochlorin ($\text{C}_{12}\text{H}_8\text{N}_2\text{O}_2$?), whilst the alcoholic solution, mixed with water, gives a pp., whence ether extracts red isatopurpurin ($\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_2$?), while white isatone ($\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_2$?) remains undissolved (Schützenberger, *Bl.* [2] 4, 170).—16. PCl_5 forms 'isatin chloride' (Baeyer, *B.* 12, 456).—17. Hydroxylamine forms nitroso-oxindole or isatoxim.—18. Alcoholic KClO_4 has no action.—19. A solution of isatin, warmed with phenyl-hydrazine, forms a pp. of the phenyl-hydrazide.—20. In presence of H_2SO_4 or ZnCl_2 isatin forms condensation products, with (2 mols. of) toluene, phenol, di-methyl-aniline, thiophene, &c., by elimination of water (1 mol.). Thus, phenol and H_2SO_4 give di-oxy-di-phenyl-oxindole $\text{C}_6\text{H}_4 \begin{array}{c} \text{C(C}_6\text{H}_4\text{OH)}_2 \\ \text{N.H.CO} \end{array}$; toluene gives di-tolyl-oxindole, while di-methyl-aniline gives tetramethyl-di-amido-di-phenyl-oxindole [284°] (Baeyer, *B.* 18, 2642).—21. When heated with phenylcyanate, for three hours at 130° , it forms the anilide of isatin ν -carboxylic acid, which crystallises from alcohol in needles [180° – 185°] (Gumpert, *J. pr.* [2] 31, 120; 32, 283).—22. Phenyl mercaptan, added to a hot alcoholic solution of isatin, forms silky needles of a compound $(\text{C}_6\text{H}_4\text{NO}_2)(\text{C}_6\text{H}_5\text{SH})$, insol. water, but decomposed by hot benzene into its components (Baumann, *B.* 18, 890).—23. By boiling with *m*-amido-benzoic acid and alcohol there is formed an acid which is termed isat-amido-benzoic acid $\text{C}_6\text{H}_4 \begin{array}{c} \text{C.NC}_6\text{H}_4\text{CO}_2\text{H} \\ \text{NH} \end{array} \text{CO}$ [253°]. *m*-Amido-benzamide gives, in like manner, the corresponding amide [$c.$ 280°] (Schiff, *A.* 218, 192).—24. Heating with tolylene-diamine forms $\text{C}_{12}\text{H}_{12}\text{N}_4$ [290°], which is probably a quinoxaline (Hinsberg, *A.* 237, 844).

Metallic derivatives.— $\text{C}_6\text{H}_4\text{AgNO}_2$: obtained by mixing isatin with water at 0° , adding KOH (1 mol.), followed immediately by AgNO_3 (1 mol.) (Baeyer a. Oeconomidis, *B.* 15, 2093). Red pp.— $\text{C}_6\text{H}_4\text{AgNO}_2\text{NH}_2$. Formed in presence of ammonia (L.)— $\text{Cu}(\text{C}_6\text{H}_4\text{NO}_2\text{NH}_2)_2$. From cupric acetate and an ammoniacal solution of isatin (Laurent). Brown pp.—Potassium isatip is present in the violet-red solution obtained by dissolving isatin in conc. KOH aq.

Indophenine reaction.—A solution of isatin

in conc. H_2SO_4 , shaken with benzene containing thiophene, is coloured blue, through formation of indophenine (*q. v.*). A similar reaction is given by most derivatives of thiophene.

Combinations with bisulphites $\text{C}_6\text{H}_4\text{NO}_2\text{KHSO}_3$, 2aq. Formed by boiling isatin with aqueous KHSO_3 , or by saturating a solution of potassium isatate with SO_2 (Laurent). Large, pale-yellow tables; *v. s.* sol. water and boiling alcohol, *sl. sol.* cold alcohol. Gives with lead acetate a pp. of isatin and lead sulphite. — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4)\text{HSO}_3$: pale yellow tables, *sl. sol.* cold water. — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4\text{C}_2\text{H}_5)\text{HSO}_3$ (Schiff, A. 144, 49). — $\text{C}_6\text{H}_4\text{NO}_2(\text{NH}_4\text{Ph})\text{HSO}_3$. Crystals; *v. sol.* water (*S.*).

Acetyl- ψ -isatin $\text{C}_6\text{H}_3\text{Ac}(\text{CO})$. [141°].

Prepared by heating isatin (1 pt.) with Ac_2O (2 pts.) for 4 hours (Suida, B. 11, 584). Yellow needles (from benzene). *V. sol.* benzene and alcohol, *sl. sol.* cold water. Resolved into isatin and acetic acid by boiling with water, or, more readily with HClAq . Cold NaOHaq dissolves it, forming $\text{C}_6\text{H}_3(\text{NHAc})(\text{CO})\text{CO}_2\text{Na}$ and, on warming, isatic acid. Chromic acid in HOAc oxidises it to $\text{NHAcC}_6\text{H}_3\text{CO}_2\text{H}$.

Benzoyl- ψ -isatin $\text{C}_6\text{H}_3\text{NBz}(\text{CO})$.

From isatin and BzCl (Schwartz, C. R. 56, 1050).

Oxim $\text{C}_6\text{H}_3\text{N}_2\text{O}_2$, i.e. $\text{C}_6\text{H}_3(\text{C}(\text{NOH})\text{N}(\text{C}(\text{OH}))$. Isat-

oxim. Nitroso-oxindole. [c. 202°]. Formed by passing nitrous acid into a 1 p.c. aqueous solution of oxindole (Baeyer & Knop, A. 140, 34). Formed also by boiling diazo-nitroso-oxindole chloride with alcohol and HCl (Gabriel & R. Meyer, B. 14, 2332). Obtained by treating isatin with hydroxylamine (Gabriel, B. 16, 518; Baeyer & Comstock, B. 16, 1706). Very slender golden needles. Decomposed by fusion. *V. sl. sol.* water, *sl. sol.* alcohol. Dissolves in KOHaq , forming a dark reddish-brown solution. Not decomposed by boiling aqueous KOH . — $\text{C}_6\text{H}_3\text{AgN}_2\text{O}_2$: orange pp., got by adding dilute NH_3 to an alcoholic solution of isatin and AgNO_3 . Dries up to a brick-red powder.

Mono-ethyl-ether of the oxim

$\text{C}_6\text{H}_3(\text{C}(\text{NOEt})\text{N})\text{C}(\text{OH})$. Isato-ethyl-oxim. [188°]. Fine yellow needles, soluble in caustic alkalis; formed by the action of ethyl iodide on the silver salt of isatoxim. By successive treatment with zinc-dust and HOAc and with FeCl_3 it is converted into isatin.

Di-ethyl-ether of the oxim

$\text{C}_6\text{H}_3(\text{C}(\text{NOEt})\text{N})\text{C}(\text{OEt})$. Ethyl-isato-ethyl-oxim. Crystalline solid; formed by the action of ethyl iodide on the silver salt of the mono-ethyl-ether (Baeyer & Comstock, B. 16, 1706).

Oxim of ψ -isatin $\text{C}_6\text{H}_3(\text{CO})(\text{NH})\text{C}(\text{NOH})$.

Isanitroso- ψ -indoxyl. Formed by the action of nitrous acid on ethyl-indoxylic acid.

$\text{C}_6\text{H}_3(\text{C}(\text{OEt})\text{NH})\text{C}(\text{CO})\text{H}$. Flat yellow needles. Decomposes at about 200°. *Sol.* alkalis and reppd. by CO_2 . With phenol and H_2SO_4 it does not give Liebermann's reaction. Reduction with zinc-dust followed by oxidation with FeCl_3 yields isatin.

Ethyl ether of the oxim of ψ -isatin $\text{C}_6\text{H}_3(\text{CO})(\text{NH})\text{C}(\text{NOEt})$. From ψ -isatoxim, KOH , and EtI : yellow plates; dissolves in sodium ethylate with a blue colour; reduction with zinc-dust followed by oxidation with FeCl_3 yields isatin. Forms a violet solution when warmed with aqueous NaOH .

Di-ethyl-derivative of the oxim of ψ -isatin $\text{C}_6\text{H}_3(\text{CO})(\text{NH})\text{C}(\text{NOEt})_2$. [99°]; yellow needles, sublimable, easily soluble in alcohol and ether, sparingly in hot water, *insol.* alkalis. On reduction with zinc-dust and oxidation with FeCl_3 it yields ethyl-pseudo-isatin (Baeyer, B. 15, 782; 16, 2191).

Phenyl-hydraside $\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}$. [211°]. Fine yellowish-red needles. Formed as a yellow crystalline pp. by boiling a solution of isatin in 1,000 pts. of water with phenyl-hydrazine hydrochloride (*q. v.*); the pp. is quite distinct with a solution of 1 in 20,000 (E. Fischer, B. 17, 877).

Chloride $\text{C}_6\text{H}_3\text{ClNO}$ i.e. $\text{C}_6\text{H}_3(\text{CO})(\text{N})\text{CCl}$.

[c. 180°]. Formed by warming isatin (5 g.) with PCl_5 (7 g.) and benzene (9 g.) (Baeyer, B. 11, 1296; 12, 456). Brown needles. Decomposed on fusion. *V. sol.* ether, forming a blue solution. Decomposed by moist air. Potash converts it into isatin. HI gives indigo; zinc-dust and HOAc do the same.

Chloro-isatin $\text{C}_6\text{H}_3\text{ClNO}$. [243°]. *S.* 1 at 0°; c. .5 at 100°. Obtained by passing chlorine in sunlight into boiling water containing isatin in suspension. The mono- and di-chloroisatin are separated by recrystallisation from alcohol, in which the former is much less soluble (Hofmann, A. 53, 12; Laurent, A. Ch. [3] 8, 462; Erdmann, A. 33, 129; Dorosh, J. pr. [2] 33, 49). Orange prisms (from alcohol). *V. sl. sol.* water and alcohol. Its solution imparts an unpleasant odour to the skin. Decomposed on fusion. Hot KOHaq forms potassium chloro-isatate. Distillation with NH_3 gives *p*-chloro-aniline. An ammoniacal solution of AgNO_3 added to an alcoholic solution of chloro-isatin ppts. $\text{C}_6\text{H}_3\text{ClAgNO}_2\text{NH}_3$.

Di-chloro-isatin $\text{C}_6\text{H}_2\text{Cl}_2\text{NO}$. [186°]. Obtained from the alcoholic mother-liquors that have yielded chloro-isatin. Small, reddish-yellow needles or short laminae (from alcohol). *M. sol.* alcohol. When thrown upon solid potash, moistened with alcohol, a red solution is formed which solidifies to a violet-black magma of $\text{C}_6\text{H}_2\text{KCl}_2\text{NO}$, the solution of which gives a pp. with AgNO_3 . Hot aqueous KOH forms potassium di-chloro-isatate. Distillation with KOH forms di-chloro-aniline. Chlorine does not act on its aqueous solution, but with its alcoholic solution it forms tetra-chloro-quinone and other bodies. KHSO_5 forms light-yellow needles of $\text{C}_6\text{H}_2\text{Cl}_2\text{NO}_2\text{KHSO}_5$, *sl. sol.* boiling water. Di-chloro-isatin (10 g.) oxidised by CrO_3 (15 g.) in glacial acetic acid (80 g.) as described under *Bromo-isatin* forms di-chloro-isatoxonic acid (*q. v.*).

Bromo-isatin $\text{C}_6\text{H}_3\text{BrNO}$, i.e.

$\text{C}_6\text{H}_3(\text{CO})(\text{N})\text{CBr}$. [255°]. Formed, together with di-bromo-isatin, by the action of bromine and water on isatin (Erdmann, J. pr.

19, 359; Hofmann, A. 53, 46). The product is exhausted with boiling water and the crystals that separate on cooling are recrystallised from alcohol whence bromo-isatin crystallises first. Orange prisms. Aqueous KOH converts it, even in the cold, into potassium bromo-isatate. Distillation with KOH yields *p*-bromo-aniline. When mixed with alcoholic ammonium sulphide and exposed to the air it yields bromo-indigo. Bromo-isatin (10 g.) is oxidised by a mixture of glacial acetic acid (90 g.) and CrO₃ (15 g.) to bromo-isatoic acid. The mixture must first be kept ice-cold, but after 12 hours it may be slowly raised to 70°. The product, when cold, is poured into cold dilute H₂SO₄, and the yellow sandy powder crystallised from a mixture of alcohol and acetone (Dorsch, J. pr. [2] 33, 45).

Acetyl derivative C₈H₅BrAcNO₂. [172°]. Formed by boiling bromo-isatin (5 pts.) with Ac₂O (8 pts.) (Baeyer a. Oeconomidis, B. 15, 2096). Long straw-yellow prisms (from benzene).

Chloride C₈H₅BrClNO. Formed by treating bromo-isatin with PCl₅ (Baeyer, B. 12, 1315). Reddish-brown needles; sol. hot benzene and ether. HI gives bromo-indigo.

Oxim C₈H₅BrNO(NOH). From isatoxim and bromine-water in the cold (Baeyer a. Knop, A. 140, 35). Crystals, sl. sol. water.

[250°]. Formed as above or by digesting bromo-isatin or isatin with bromine in sunshine. Formed also by heating bromo-isatin (1 mol.) with bromine (2 mols.) in HOAc for 20 hours (Baeyer a. Oeconomidis, B. 15, 2098). Orange prisms (from alcohol). Gives di-bromo-aniline when distilled with KOH.—C₈H₅Br.KNO₂: bluish-violet scales, sl. sol. water. Very stable but converted into di-bromo-isatate by warming with KOHAq.—AgA': brownish-violet powder.—C₈H₅Br.NO₂.KHSO₅: yellow solid, v. sl. sol. water.

Oxim C₈H₅Br.O₂N₂ or

$$\begin{array}{c} \text{C(OH)} \\ \text{C} \\ \text{C(OH)} \end{array} \begin{array}{c} \text{C(OH)} \\ \text{N} \\ \text{C(OH)} \end{array} \text{C(OH).}$$
 Formed by the action of hydroxylamine on di-bromo-isatin (Baeyer a. Comstock, B. 16, 1708). Yellow pointed needles. Carbonises without melting at about 255°. Sol. caustic alkalis but precipitated by CO₂.

Mono-ethyl-ether of the oxim

$$\begin{array}{c} \text{C(OEt)} \\ \text{C} \\ \text{C(OEt)} \end{array} \begin{array}{c} \text{C(OEt)} \\ \text{N} \\ \text{C(OEt)} \end{array} \text{C(OEt).}$$
 Di-bromo-isato-ethyl-oxim. [252°]. Yellow needles; formed by the action of ethyl-iodide on the silver salt of di-bromo-isatoxim.

Di-ethyl-ether of the oxim

$$\begin{array}{c} \text{C(OEt)} \\ \text{C} \\ \text{C(OEt)} \end{array} \begin{array}{c} \text{C(OEt)} \\ \text{N} \\ \text{C(OEt)} \end{array} \text{C(OEt).}$$
 Di-bromo-ethyl-isato-ethyl-oxim. [116°]. Long^o yellow, silky needles; formed by the action of ethyl iodide on the silver salt of the mono-ethyl-ether.

Tri-bromb-isatin. Oxim

$$\begin{array}{c} \text{C(OH)} \\ \text{C} \\ \text{C(OH)} \end{array} \begin{array}{c} \text{C(OH)} \\ \text{N} \\ \text{C(OH)} \end{array} \text{C(OH).}$$
 [162°]. From the oxim of isatin and bromine in excess (B. a. K.). Dirty violet needles (from alcohol). Insol.

water, v. sol. boiling alcohol. At 190° it sublimes as red needles.

Nitro-isatin C₈H₅NO₂(NO₂). [226°–230°]. Prepared by nitration of isatin dissolved in H₂SO₄, by addition of powdered KNO₃ (Baeyer, B. 12, 1312). Sparingly soluble in water, more easily in alcohol.

Bromo-nitro-isatin

C₈H₅(NO₂)Br < $\begin{array}{c} \text{CO} \\ \text{N} \end{array}$ > C.OH. [237°]. From bromo-isatin, KNO₃, and H₂SO₄ (Dorsch). Clumps of orange crystals (from alcohol). Sol. acetone, glacial acetic acid and alcohol, sl. sol. benzene and chloroform, v. sl. sol. water and ether. Forms a dark-red solution in NaOH.Aq, whence an orange powder presently separates.

ALKYL DERIVATIVES.

Alkyl derivatives of isatin are either derived from the stable form C₈H₅ < $\begin{array}{c} \text{CO} \\ \text{N} \end{array}$ > C.OH

or from the transition form C₈H₅ < $\begin{array}{c} \text{CO} \\ \text{NH} \end{array}$ > CO (pseudo-isatin). Alkyl iodides acting on silver-isatin form alkyl derivatives of stable isatin C₈H₅ < $\begin{array}{c} \text{CO} \\ \text{N} \end{array}$ > C.OH.

Alkyl derivatives of pseudo-isatin

C₈H₅ < $\begin{array}{c} \text{CO} \\ \text{NR} \end{array}$ > CO are formed by the action of an alkaline solution of bromine or chlorine followed by alcoholic NaOH on the methyl-, ethyl-, phenyl-, &c. -indole-carboxylic acids which are obtained by the action of HCl on phenyl-methyl-hydrazine-pyruvic acid, phenyl-ethyl-hydrazine-pyruvic acid, &c. (Fischer a. Hess, B. 17, 559).

Methyl derivative of isatin C₈H₅O₂N(CH₃) i.e. C₈H₅ < $\begin{array}{c} \text{CO} \\ \text{N} \end{array}$ > COMe. [102°]. Formed by the action of methyl iodide on the silver compound of isatin (Baeyer a. Oeconomidis, B. 15, 2093). Red trimetric prisms. Sol. ether, acetone, benzene, and CS₂, less easily in alcohol, v. sl. sol. ligroin. It changes on keeping into methyl-isatoid. Slowly dissolves in dilute KOHAq, forming a solution from which acids ppt. isatin. Its solution in alcoholic ammonium sulphide forms indigo when exposed to the air.

Methyl-isatoid C₈H₅N₂O₂(?) [219°]. Formed by spontaneous change by keeping methyl-isatin (Baeyer a. Oeconomidis, B. 15, 2094). Small yellow needles; sparingly soluble in all solvents. Dissolves in dilute NaOH on boiling, and on adding acid isatin is precipitated.

Methyl derivative of bromo-isatin C₈H₅BrO₂NMe. [147°]. Formed by the action of MeI on the silver compound of bromo-isatin (Baeyer a. Oeconomidis, B. 15, 2095). Red needles.

Bromo-methyl-isatoid [231°]. Formed by spontaneous change of methyl-bromo-isatin by keeping (B. a. O.).

Methyl-pseudo-isatin C₈H₅NO₂ i.e.

Formation.—1. By the action of a cold alkaline solution of bromine or chlorine followed by hot alcoholic NaOH on methyl-indole-carboxylic acid [212°], which is obtained by heating phenyl-methyl-hydrazine-pyruvic acid with HCl (Fischer a. Hess, B. 17, 563).—2. By boiling di-

bromo-methyl-oxindole with water (Colman, *C. J.* 55, 5; *A.* 248, 118).

Reactions.—Dissolves in alkalis with a yellow colour. With H_2SO_4 and benzene containing thiophene it gives the indophenine reaction. Gives a crystalline compound with phenyl-hydrazine. Yields the same product on oxidation in alkaline solutions as in acid solution, viz. methyl-di-oxindole.

Oxim $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{C(N.OH)} \\ \text{N(CH}_3\text{)} \end{smallmatrix} \text{CO}$. [180°–163°].

From methyl-pseudo-isatin and hydroxylamine sulphate in hot aqueous solution (Colman, *C. J.* 55, 6). Tufts of small pale-yellow needles; m. sol. hot water, sl. sol. cold water, v. sol. alcohol, acetone, ether, and benzene.

Phenyl hydrazide $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{C}=\text{N.H.Ph} \\ \text{NMe} \end{smallmatrix} \text{CO}$.

[146°]. Formed by the action of phenyl-hydrazine hydrochloride and NaOAc on an aqueous solution of methyl- ψ -isatin. A less pure product is produced by the action of phenyl-hydrazine hydrochloride on dibromomethyl-oxindole (Colman). Fascicular group of small yellow needles; insol. water and petroleum ether, sl. sol. ether, v. sol. hot alcohol or benzene.

p-Methyl-isatin $\text{C}_6\text{H}_4\text{MeNO}_2$, i.e.

$\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{CO} \\ \text{N} \end{smallmatrix} \text{COH}$ (stable form) or

$\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{CO}$ (transition form).

Tolisin. Anhydride of amido-tolyl-glyoxylic acid. [184°] (P.); [187°] (M.).

Formation.—From *p*-toluidine and di-chloro-acetic acid by digestion in alcoholic solution, the resulting *p*-toluide (*p*-tolyl-methyl-imesatin)

$\text{C}=\text{NCH}_2\text{Me}$

$\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{CO} \\ \text{NH} \end{smallmatrix} \text{CO}$ being decomposed by

HCl , and the crude product purified by boiling with aqueous KOH , ppg. with HCl , and crystallising from alcohol and afterwards from water (P. J. Meyer, *B.* 16, 2261; Fr. Baeyer & Co., *B.* Ref. 17, 867; Panatovic, *J. pr.* [2] 33, 57).

Properties.—Red crystals or glistening red plates. Sol. hot water and alcohol, sl. sol. cold water, v. sol. hot HCl aq. Dissolves in cold alkalis with a deep-violet colour, and on heating or standing it then takes up water, becoming yellow and forming methyl-isatinic acid. Dissolves in conc. H_2SO_4 with a red colour. Gives the indophenine reaction. CrO_3 in acetic acid forms methyl-isatinic acid. Boiling with Ac_2O for three hours forms the acetyl derivative of methyl- ψ -isatin.

Acetyl derivative of methyl- ψ -isatin $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{CO} \\ \text{N} \end{smallmatrix} \text{CO}$. [172°]. Formed by boiling *p*-methyl- ψ -isatin with Ac_2O for 3 hours (Panatovic, *J. pr.* [2] 33, 71). Formed also by the action of HCl upon the acetyl derivative of *p*-methyl- ψ -isatin *p*-toluide (Duisberg, *B.* 18, 197). Lemon-yellow needles (from benzene); sol. chloroform and benzene, sl. sol. water, alcohol, ether, ligroin, and CS_2 . Converted by cold dilute alkalis into acetyl-*p*-methyl-isatinic acid. Alcoholic NH_3 converts it into the amide of acetyl-*p*-methyl-isatinic acid $\text{C}_6\text{H}_4\text{Me}(\text{NHAc})\text{COCONH}_2$, which crystallises from alcohol in trimetric columns [141°]. CrO_3

in HOAc oxidises it to methyl-isatinic acid, which crystallises from boiling alcohol in trimetric plates and, when heated, decomposes at 245° with great increase in bulk, finally melting at 300°.

Oxim $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{C(N.OH)} \\ \text{N:C(OH)} \end{smallmatrix}$. **Isonitroso-methyl-oxindole**. [226°]. Formed by the action of hydroxylamine (base) on *p*-methyl-isatin (P. J. Meyer, *B.* 16, 2268). Long yellow prisms; sol. alcohol and NaOH , sl. sol. water.

Phenyl-hydrazide of methyl-isatin $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{C(N.HPh)} \\ \text{N} \end{smallmatrix} \text{COH}$. From *p*-methyl-isatin and phenyl-hydrazine (P.). Golden needles (from chloroform). Nearly insol. water, sol. alcohol. May be sublimed at 240°, but melts above 300° with evolution of gas.

Di-phenyl-hydrazide of methyl- ψ -isatin $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{C(N.HPh)} \\ \text{NH} \end{smallmatrix} \text{CO(N.HPh)}$. [255°]

Formed by warming the acetyl derivative of methyl- ψ -isatin with phenyl-hydrazine (P.). Yellow trimetric columns (from alcohol) decomposed by fusion. Nearly insol. water, sol. chloroform.

Imide $\text{C}_6\text{H}_4\text{N}_2\text{O}$ or $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_2$. **p-Methyl-imesatin**. Formed by heating *p*-methyl-isatin-*p*-toluide with alcoholic NH_3 at 100° (P. J. Meyer, *B.* 16, 2264). Nearly colourless fine silky needles. V. sl. sol. hot alcohol and hot water. Insol. cold alcohol and water. Is not re-converted into *p*-methyl-isatin by acids or alkalis.

Phenyl-imide $\text{C}_{13}\text{H}_{12}\text{N}_2\text{O}$ i.e.

$\text{C}_6\text{H}_4(\text{CH}_3) \begin{smallmatrix} \text{C(NPh)} \\ \text{N} \end{smallmatrix} \text{CO.H}$. **Methyl-isatin anilide**. **Phenyl-methyl-imesatin**. [240°].

Formed by heating *p*-methyl-isatin with an absolute alcoholic solution of aniline (Meyer, *B.* 16, 2267). Thick yellowish-red tables or prisms. Sol. hot alcohol, sl. sol. cold alcohol and water. Heated with acids or caustic alkalis it is resolved into its constituents.

o-Tolyl-imide $\text{C}_{10}\text{H}_8\text{N}_2\text{O}$ i.e.

$\text{C}_6\text{H}_4(\text{CH}_3) \begin{smallmatrix} \text{C(NC}_6\text{H}_5) \\ \text{N} \end{smallmatrix} \text{CO.H}$. **o-Toluide of methyl-isatin**. **o-Tolyl-p-methyl-imesatin**.

[191°]. Red prismatic crystals. Formed by heating *p*-methyl-isatin with an absolute alcoholic solution of *o*-toluidine. By HCl or hot NaOH it is resolved into its constituents (Meyer, *B.* 16, 2268).

p-Tolyl-imide $\text{C}_{10}\text{H}_8\text{N}_2\text{O}$ i.e.

$\text{C}_6\text{H}_4(\text{CH}_3) \begin{smallmatrix} \text{C(NC}_6\text{H}_5) \\ \text{N} \end{smallmatrix} \text{CO.H}$. **p-Toluide of methyl-isatin**. **p-Tolyl-p-methyl-imesatin**.

[269°]. Formed by heating di-chloro-acetic acid (1 mol.) with *p*-toluidine (4 mols.) at 100° C., either alone or in aqueous or alcoholic solution; the yield is 70 p.c. **p-Tolyl-amido-*p*-methyl-oxindole** $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{NH} \\ \text{CH} \end{smallmatrix} \text{CO}$ is

first formed and then undergoes oxidation by absorption of oxygen from the air. Formed also by heating di-chloroacetamide (1 mol.) with *p*-toluidine (8 mols.); and by heating *p*-methyl-isatin with an absolute alcoholic solution of *p*-toluidine (Meyer, *B.* 16, 2261). Glistening yellow needles or plates. Sol. ether and hot alcohol, sparingly sol. cold alcohol, insol. water. By cold

HCl it is resolved into *p*-toluidine and *p*-methyl-isatin. Hot HCl or hot NaOH gives *p*-methyl-isatin. Sodium salt crystallises in red prisms, decomposed by water.

Acetyl derivative

$C_6H_5Me \begin{smallmatrix} > CO \\ \swarrow NAc \\ \searrow N(C_6H_5) \end{smallmatrix}$. [122°]. Glistening red needles; insol. water. By HCl it is split up into *p*-toluidine and the acetyl derivative of *p*-methyl-pseudo-isatin (Duisberg, B. 18, 190).

Bromo-p-toluide $C_6H_4BrN_2O$. [210°]. Red needles or prisms. By heating with acids or alkalis it is split up into its constituents (P. J. Meyer, B. 16, 2287).

o-Di-methyl- ψ -isatin $C_6H_4Me \begin{smallmatrix} > CO \\ \swarrow NMe \\ \searrow NMe \end{smallmatrix}$ CO.

Methyl- ψ -o-toluisatin. [157°]. Formed by adding pyruvic acid to a solution of methyl-*o*-tolyl-hydrazine to dilute HCl, and warming the resulting oil with a large quantity of phosphoric acid (S.G. 1.17). The resulting di-methyl-indole carboxylic acid is then warmed with NaOCl in slightly alkaline solution, when a product [152°] is obtained, which when warmed with water yields the di-methyl-isatin (Hegel, A. 232, 221). Brick-red needles (from water).

p-Di-methyl- ψ -isatin $C_6H_4Me \begin{smallmatrix} > CO \\ \swarrow NMe \\ \searrow NMe \end{smallmatrix}$ CO. [148°]. Formed in like manner from methyl-*p*-tolyl-hydrazine and pyruvic acid; the di-methyl-indole carboxylic acid giving with alkaline hypochlorite a chlorinated compound crystallising in yellow needles [135°] which yield the di-methyl-isatin on dissolving in water (H.). Red needles.

Ethyl-pseudo-isatin $C_6H_4 \begin{smallmatrix} > CO \\ \swarrow NEt \\ \searrow NEt \end{smallmatrix}$ CO. *Lactam of ethyl-isatinic acid*. [95°].

Formation.—1. By the action of a cold alkaline solution of chlorine followed by hot alcoholic NaOH on ethyl-indole carboxylic acid [183°] which is obtained by the action of HCl on phenyl-ethyl-hydrazine-pyruvic acid (F. Fischer a. Hess, B. 17, 566).—2. By reduction of the di-ethyl derivative of pseudo-isatin- α -oxim $C_6H_4 \begin{smallmatrix} > CO \\ \swarrow NEt \\ \searrow NEt \end{smallmatrix}$ C(NOEt) with zinc-dust and oxidation of the product with FeCl₃ (Baeyer, B. 16, 2193). Large red plates, sol. hot water, alcohol and ether. With thiophene and H₂SO₄ it gives a blue colouring matter soluble in ether. It dissolves in alkalis with a yellow colour, at once forming a salt of ethyl-isatinic acid $C_6H_4 \begin{smallmatrix} > CO.CO.H \\ \swarrow NHEt \\ \searrow NHEt \end{smallmatrix}$.

Ethyl-pseudo-isatin α -oxim . . .

$C_6H_4 \begin{smallmatrix} > C(OH) \\ \swarrow NEt \\ \searrow NEt \end{smallmatrix}$ CO. [162°]. Yellow four-sided prisms. Formed by the action of hydroxylamine on ethyl-pseudo-isatin. On reduction with zinc-dust followed by oxidation with FeCl₃ it yields ethyl-pseudo-isatin. It does not yield indigo on treatment with ammonium sulphide (Baeyer, B. 16, 2198).

Ethyl-pseudo-isatin α -oxim. *Ethyl-eigher* $C_6H_4 \begin{smallmatrix} > CO \\ \swarrow NEt \\ \searrow NEt \end{smallmatrix}$ C(NHEt). [99°]. From the ethyl ether of the α -oxim of ψ -isatin by further ethylation (Baeyer, B. 16, 2191). Yellow needles, v.

sol. alcohol and ether, sl. sol. hot water. May be sublimed. Insol. alkalis. After reduction with zinc-dust, on oxidation with FeCl₃ it yields ethyl- ψ -isatin.

Bromo-ethyl-isatin $C_6H_4BrN_2O$ *Et* *s.*

$C_6H_4Br \begin{smallmatrix} > CO \\ \swarrow N \\ \searrow N \end{smallmatrix}$ COEt. [109°]. From the silver compound of bromo-isatin and EtI (Baeyer a. Oeconomidis, B. 15, 2095). Long red prismatic needles (from benzene). On keeping it slowly changes into bromo-ethyl-isatoid.

Bromo-ethyl-isatoid $C_6H_4BrN_2O$. [245°]. Fine needles. Sparingly soluble in all solvents, most easily in hot alcohol and acetone. Formed by spontaneous change of ethyl-bromo-isatin by keeping; also by the action of acetic anhydride on ethyl bromo-isatin (Baeyer a. Oeconomidis, B. 15, 2095).

p-Ethyl-isatin $C_6H_4NO_2$ *s.*

$C_6H_4Et \begin{smallmatrix} > CO \\ \swarrow N \\ \searrow N \end{smallmatrix}$ CO.H. [137°]. Lopp red needles (Paucksch, B. 17, 2805). Formed by heating with HClAq the product of the action of dichloro-acetic acid on *p*-amido-phenyl-ethane $C_6H_4Et(NH_2)$ [1.4].

Di-bromo-ethyl-isatin $C_6H_2O_2N_2Br_2Et$ *s.*

$C_6H_2Br \begin{smallmatrix} > CO \\ \swarrow N \\ \searrow N \end{smallmatrix}$ COEt. [89°]. From silver di-bromo-isatin and EtI (B. a. O.). Red crystals.

p-Methyl- ψ -ethyl- ψ -isatin

$C_6H_4Me \begin{smallmatrix} > CO \\ \swarrow NEt \\ \searrow NEt \end{smallmatrix}$ CO. [110°] *Ethyl- ψ -p-toluisatin*. Formed from the *p*-toluide by treatment with conc. HClAq (Duisberg, B. 18, 197). Formed also from methyl-ethyl-indole carboxylic acid by treatment with a weak alkaline solution of NaOCl, and warming the resulting pp. with water (Hegel, A. 232, 219). Red needles or prisms; v. sol. alcohol, ether, benzene, and CS₂, sl. sol. water and ligroin. Sol. aqueous alkalis. Gives the indophenine reaction.

p-Tolylimide $C_6H_4Me \begin{smallmatrix} > C(NC_6H_4Me) \\ \swarrow N \\ \searrow N \end{smallmatrix}$ CO.

p-Toluide [152°]. Formed by boiling the *p*-tolylimide of *p*-methyl isatin with NaOEt and EtBr (Duisberg, B. 18, 198). Large orange-red prisms; v. sol. alcohol, acetic acid, benzene, and CS₂, sl. sol. ether, insol. water. Split up by HCl into *p*-toluidine and methyl-ethyl- ψ -isatin.

Isobutyl-bromo-isatin

$C_6H_4Br \begin{smallmatrix} > CO \\ \swarrow N \\ \searrow N \end{smallmatrix}$ COC₄H₉. Crystallises with difficulty. Is converted by Ac₂O into iso-butyl-bromo-isatoid $C_6H_4BrN_2O$ [210°] which crystallises in slender needles, sl. sol. all solvents (Baeyer a. Oeconomidis, B. 15, 2097).

Benzyl- ψ -isatin $C_6H_4 \begin{smallmatrix} > CO.CO \\ \swarrow N(CH_2Ph) \\ \searrow N(CH_2Ph) \end{smallmatrix}$ CO. [181°].

Formed by adding a solution of sodium benzyl-indole carboxylate to one of NaOCl. The pp. is dissolved in alcoholic NaOH, warmed gently, diluted with water, freed from alcohol by distillation, and ppd. with water (Antrick, A. 227, 364). Long silky red needles (from water). Almost insol. cold water, v. sol. alcohol and ether.

Phenol-isatin *v.* *Di-oxi-di-phenyl-oxindole*. *Tolyl-isatin* *v.* *Di-tolyl-oxindole*.

(*a*)-Naphth-isatin $C_{10}H_7 \begin{smallmatrix} > CO \\ \swarrow NH \\ \searrow NH \end{smallmatrix}$ CO or

$C_{10}H_7 \langle \begin{smallmatrix} N \\ CO \end{smallmatrix} \rangle C.OH$. [255°]: Formed by dissolving (α)-naphthoxindole in alcohol and adding HOAc and $NaNO_2$. The isonitroso-derivative so obtained is reduced with Sn and HCl, and subsequently oxidised with $FeCl_3$ (Hinsberg, B. 21, 117). Red needles. Forms a compound with phenyl-hydrazine [270°].

(β)-Naphth-isatin $C_{10}H_7 \langle \begin{smallmatrix} N \\ CO \end{smallmatrix} \rangle C.OH$. [248°].

Formed by dissolving (β)-naphthoxindole in HOAc and adding sodium nitrite. The isonitroso-body formed yields on reduction with Sn and HCl, and subsequent oxidation with $FeCl_3$, the isatin (Hinsberg, B. 21, 115). Red needles, v. sol. ordinary solvents.

AMMONIACAL DERIVATIVES OF ISATIN.

Imesatin $C_{10}H_7N_2O$ i.e. $C_6H_5 \langle \begin{smallmatrix} CO \\ N \end{smallmatrix} \rangle C.NH_2$ or

$C_6H_5 \langle \begin{smallmatrix} CO \\ NH \end{smallmatrix} \rangle C.NH (?)$ or $C_6H_5 \langle \begin{smallmatrix} C(NH) \\ N \end{smallmatrix} \rangle C.OH$.

Isatin-imide (?) Obtained by Laurent (J. pr. 25, 457) by passing dry NH_3 into a boiling alcoholic solution of isatin containing a little isatin in suspension. Could not be obtained by Sommaruga (B. 10, 432). Rectangular prisms: insol. water, v. sl. sol. ether, m. sol. boiling alcohol. Readily decomposed by heating with alcohol and HClAq into isatin and NH_3 . KOH acts in like manner.

Chloro-imesatin $C_6H_4ClN_2O$. From chloro-isatin and alcoholic NH_3 (Laurent). Yellow six-sided prismatic tables; v. sl. sol. boiling alcohol, insol. ether. Dissolves in KOH, giving a red liquid.

Bromo-imesatin $C_6H_4BrN_2O$. From bromo-isatin and boiling alcoholic NH_3 (Gerike, Z. 1865, 593). Yellowish-brown crystalline mass.

Iso-amyl-imesatin $C_{10}H_7(C_4H_9)N_2O$ i.e.

$C_6H_5 \langle \begin{smallmatrix} CO \\ N \end{smallmatrix} \rangle C.NF.C_4H_9$ or

$C_6H_5 \langle \begin{smallmatrix} C(NC_4H_9) \\ N \end{smallmatrix} \rangle C.OH (?)$. Formed by heating isatin with isocamylamine (Schiff, A. 144, 53; Z. [3] 4, 13). Yellow laminae; sl. sol. ether, v. sol. alcohol. Decomposed by dilute acids or by prolonged treatment with water into isatin and isocamylamine.

Phenyl-imesatin $C_6H_5(C_6H_5)N_2O$. *Anilide of isatin*. From isatin and aniline in boiling alcoholic solution (Engelhardt, J. 1855, 341). Formed also by heating the compound of isatin with bisulphite of aniline, and crystallising from ether-alcohol.

Chloro-phenyl-imesatin $C_6H_4(C_6H_4Cl)N_2O$. From isatin and chloro-aniline (E.). Yellowish crystals.

Bromo-phenyl-imesatin $C_6H_4(C_6H_4Br)N_2O$. Resembles the preceding (E.).

Phenyl-chloro-imesatin $C_6H_4Cl(C_6H_5)N_2O$. Formed by adding aniline to a boiling solution of chloro-isatin in alcohol (Engelhardt, J. pr. 66, 260). Yellow needles; insol. water, v. sol. hot alcohol. Resolved by boiling dilute acids into chloro-isatin and aniline. Potash gives aniline and potassium chloro-isatin.

Phenyl-bromo-imesatin $C_6H_4Br(C_6H_5)N_2O$. Resembles the above (E.).

Di-phenyl-di-ethyl-di-amide of isatin $C_{10}H_7N_2O$ i.e. $C_6H_5 \langle \begin{smallmatrix} CO \\ NH \end{smallmatrix} \rangle C(NPhEt)_2$, or

$C_6H_5 \langle \begin{smallmatrix} C(NPhEt)_2 \\ N \end{smallmatrix} \rangle C.OH (?)$. "So-called phenyl-ethyl-imesatin. From isatin by heating with ethyl-aniline (Schiff). Yellow laminae; sl. sol. ether, v. sol. alkalis. Split up by acids, alkalis, or hot water into isatin and ethyl-aniline.

p-Methyl-imesatin v. *Imide of p-Methyl-isatin (supra)*.

Phenyl-p-methyl-imesatin v. *Anilide of p-methyl-isatin (supra)*.

Imasatin $C_{10}H_7N_2O_2$. Formed by passing NH_3 into a boiling saturated solution of isatin in dilute alcohol (Laurent, A. Ch. [8] 3, 488). Greyish-yellow granules; insol. water and ether, v. sl. sol. boiling alcohol. Not attacked by boiling aqueous HCl. Caustic potash dissolves it, and the solution is pptd. by dilute HClAq.

Di-chloro-imesatin $C_6H_4Cl_2N_2O_2$. From chloro-isatin and alcoholic NH_3 (L.). Slightly reddish powder.

Di-bromo-imesatin $C_6H_4Br_2N_2O_2$. Formed by heating an alcoholic solution of bromo-isatin with ammonia (Gerike, Z. 1865, 593). Brownish-yellow crystalline granules.

Tetra-bromo-imesatin $C_6H_4Br_4N_2O_2$. From tetra-bromo-isatin and alcoholic NH_3 . Reddish-yellow scales (L.).

Amasatin $C_{10}H_7N_2O_2$. "Isamide. Amide of Isamic acid? One of the products of the action of ammonia on isatin. Prepared by heating ammonium isamate till water is given off, and washing the residue with water (Laurent, A. Ch. [3] 3, 488; J. pr. 35, 117). Yellow powder; insol. water, nearly insol. ether, v. sl. sol. alcohol, m. sol. boiling alcoholic NH_3 . Cold KOHAq dissolves it, giving off NH_3 , and forming a yellow liquid containing potassium isamate. HClAq forms a violet solution containing isamic acid.

Di-chloro-amasatin $C_6H_4Cl_2N_2O_2$. Yellow powder, formed by evaporating a solution of ammonium chloro-isamate (L.).

Tetra-chloro-amasatin $C_6H_4Cl_4N_2O_2$. Formed by heating ammonium di-chloro-isamate.

Di-bromo-amasatin $C_6H_4Br_2N_2O_2$ (?).

Formed by evaporating an aqueous solution of ammonium bromo-isamate and treating the pasty residue with water (Gerike). Orange-yellow substance, sl. sol. water, insol. alcohol and ether. Dissolves with violet colour in acids.

Amisatin $C_{10}H_7N_3O_2$. A product of the action of dilute alcoholic ammonia on isatin and pptd. by adding water to the solution after isatin and isatiling have crystallised out (L.). Minute needles, insol. alcohol, sol. alcoholic potash.

Isamic acid $C_{10}H_7N_2O_2$. Produced by the action of warm ammonia on isatin; but is best prepared by dissolving isatin to saturation in aqueous KOH, evaporating the solution to dryness, dissolving in alcohol, adding a very concentrated solution of ammonium sulphate, filtering, and evaporating to dryness. The residue contains amasatin and ammonium isamate, and the latter may be dissolved in alcohol, whence, after addition of HCl, isamic acid crystallises (Laurent, A. Ch. [8] 3, 490). Ruby-coloured hexagonal tablets or scarlet trimetric laminae. Sl. sol. boiling water, forming a yellow

low solution; v. sol. hot alcohol, m. sol. ether. Aqueous HCl dissolves it with violet colour, and it separates again from the solution in violet crystals turned red by water. Boiling dilute acids split it up into isatin and ammonia. Bromine forms 'indoliprime,' a yellow substance $C_{12}H_7Br_2N_2O_2$, insol. water.

Salts.— NH_4^+ : small needles, or very acute minute rhombs. When strongly heated it gives off water and forms amasatin. Its solution does not ppt. salts of Ba, Ca, or Mg, but gives a yellow pp. with lead acetate and with $AgNO_3$, and a red pp. with $HgCl_2$.—The potassium salt may be boiled without decomposing.— Ag^+ .

Di-chloro-isamic acid $C_{12}H_7Cl_2N_2O_2$. Formed by adding HCl to a solution of di-chloro-amasatin in dilute KOH and crystallising the brick-red pp. from alcohol (L.). Bright-red elongated hexagonal laminae. More sol. alcohol and ether than isamic acid. Forms yellow solutions. Decomposed by distillation. HClAq forms a violet solution, but on boiling it is split up into NH_3 and chloro-isatin.

Tetra-chloro-isamic acid $C_{12}H_5Cl_4N_2O_2$. By boiling tetra-chloro-amasatin with alcohol and adding silver nitrate a flocculent precipitate of $C_{12}H_5AgCl_4N_2O_2$ is formed (L.).

Di-bromo-isamic acid $C_{12}H_7Br_2N_2O_2$. Formed by dissolving di-bromo-amasatin in KOHAq and neutralising with dilute HCl (Gerike). Red powder, nearly insol. water, v. sol. alcohol and ether. HClAq gives a violet solution. Boiling KOHAq gives bromo-isamic acid.— KA^+ : yellow needles, sl. sol. water.— BAA^+ .

Isatimide $C_{12}H_9N_2O$. Formed by passing dry NH_3 over isatin moistened with alcohol (86 to 100 p.c.). When absolute alcohol is used, imasatin first crystallises out, and the filtrate deposits isatimide as a yellow crystalline powder. Insol. water, scarcely sol. boiling alcohol or ether, v. sol. boiling alcoholic NH_3 . Potash dissolves it with yellow colour and evolution of NH_3 , the liquid then containing isatin.

Isatillim $C_{12}H_9N_2O_2$ (?). Sometimes formed when dry NH_3 is passed over isatin moistened with alcohol, separating from the alcoholic filtrate from which isatimide has separated (Laurent, *J. pr.* 35, 121). Yellow amorphous flocks, easily decomposed by KOH.

Di-isatin diamide $C_{12}H_7N_2O_2$. Formed by saturating an alcoholic solution of isatin with dry NH_3 and heating to 100° for 24 hours. The product is filtered boiling, the filtrate containing deoxy-igido-isatin, while the di-isatin diamide and oxydiamidoisatin diamide which remain on the filter are separated by treatment with water in which the di-isatin diamide is the less soluble (E. von Sommaruga, *A.* 190, 867; *B.* 11, 1082; 12, 980). Pale yellow crystals, sl. sol. alcohol and water. Nitrous acid forms some di-isatin amide.

Salts.— B^+HCl : yellow crystalline powder, almost insol. cold water.— B^+HNO_2 : yellow needles.— B^+HSO_4 : yellow needles. Not decomposed by heating with water at 100°.— $B^+H_2CrO_4$: orange powder.

Di-isatin amide $C_{12}H_9N_2O_2$. [252°]. Formed by warming di-isatin diamide with dilute KOH and ppg. with HCl (Sommaruga, *M.* 1, 579). Small yellowish needles (from alcohol). Scarcely sol. water, v. sol. alcohol.— $C_{12}H_9(NH_2)_2N_2O_2$:

silvery scales.— $C_{12}H_9KN_2O_2$ 1½ aq: silvery plates or needles.

Dihydrate $C_{12}H_{11}N_2O_2$. [218°]. Formed by treating di-isatin amide or di-isatin diamide with sodium-amalgam (Sommaruga, *A.* 194, 88). Slender needles (from alcohol); scarcely sol. water and ether. Oxidised by boiling with HgO or aqueous $FeCl_3$ to di-isatin amide. Not affected by aqueous KOH (S.G. 1.27) at 190°.— $NaC_{12}H_{11}N_2O_2$: long colourless needles, v. sol. hot water.— $KC_{12}H_{11}N_2O_2$: broad needles with silky lustre.

Oxy-diamido-di-isatin diamide $C_{12}H_7N_2O_2$. **Oxydiamidodiamidoisatin**. [295°–300°]. Formed as above (S.). Large colourless needles. Sol. water, v. e. sol. alcohol. Dissolves readily in acids, and is not reppd. from these solutions by NH_3 . Boiling with water and sodium-amalgam converts it into di-amido-di-hydrindic acid. The solutions of its salts show intense red fluorescence.— B^+HNO_2 : granules, v. sol. hot water.— $B^+H_2SO_4$: prisms.

Di-amido-di-hydrindic acid $C_{12}H_9N_2O_2$. [217°]. Formed as above. Crystalline granules. Decomposed on fusion. V. sol. hot water. Oxidised by chromic acid mixture to 'di-imido-di-hydrindin dicarboxylic' acid $C_{12}H_7N_2O_4$, which crystallises from hot water in needles.

Deoxyimido-diisatin $C_{12}H_9N_2O_2$. [210°]. Formed as mentioned under diisatin diamide (S.), and purified by solution in aqueous KOH and ppg. by an acid. Yellowish powder. Decomposed by fusion. V. sol. alcohol, hot water, and alkalis.

Oxy-amido-hydro-isatin, so-called $C_{12}H_{11}N_2O_2$. Formed by treating the preceding body with sodium-amalgam or by heating it with KOHAq in sealed tubes at 100° (S.). Yellowish amorphous powder, insol. water, v. sol. alcohol. Decomposes at 188° without fusion.

ISATIN CARBOXYLIC ACID. Anilide.
 $C_{12}H_9N_2O_2$, i.e. $C_{12}H_9NO.CONPhH$, probably CO .

$C_6H_5 < > CO$. **Carbanilido-Isatin**. [180°–183°].

Formed by heating isatin for 3 hours at 180° with phenyl cyanate (Gumpert, *J. pr.* [2] 32, 283). Crystallises from benzene in canary-yellow needles. Spl. alcohol, ether, and glacial acetic acid.

Reactions.—1. When fused it forms isatin and phenyl cyanate (compare the formation of isatin from acetyl-isatin).—2. With H_2SO_4 and crude benzene it gives the indophenin reaction. 3. Dissolves in warm, dilute KOH forming potassic carbanilido-isatate. HCl throws down sparingly soluble carbanilido-isatic acid, $NPhH.CO.NH.C_6H_5.CO.CO_2H$, [170°–180°, with decomposition]. The acid is very stable, but by heating at 110° for a long time it loses H_2O , changing back to carbanilido-isatin. Carbanilido-isatic acid, when heated with ethyl or methyl alcohol, splits off CO_2 and H_2O forming $C_{12}H_9N_2O_2$ [175°], and $C_{12}H_9N_2O_2$ [197°], respectively. 4. Converted by amines into amides of carbanilido-isatic acid, thus alcoholic NH_3 at 100° forms $NPhH.CO.NH.C_6H_5.CO.CO.NH_2$ [229°], crystallising from alcohol in needles. It dissolves in dilute NaOH, but is reppd. unaltered by HCl. When dissolved in glacial acetic acid it is converted by N_2O into an indifferent body, $C_{12}H_9N_2O_2$ [270°].—5. $NEtH_3$,

o-amido-benzoate crystallising in needles [70°] (G. Schmidt & A. E. v. Meyer, *J. pr.* [2] 36, 370).—14. Long boiling with glacial acetic acid forms an amorphous compound $C_{12}H_{11}N_3O_6$, v. sl. sol. ordinary solvents, which yields *o*-amido-benzoic acid when heated with HCl or dilute H_2SO_4 (G. Schmidt, *J. pr.* [2] 36, 380).—15. Heating with Ac_2O gives acetyl-*o*-amido-benzoic acid [180°] (S.).—16. With hydroxylamine it forms *o*-amido-benzoyl-hydroxylamine (E. v. Meyer & A. T. Bell-

mann, *J. pr.* [2] 33, 19) $C_6H_4 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix} + H_2NOH$
 $= C_6H_4(NH_2)CO.NH(OH) + CO_2$.—17. With phenyl-hydrazine it forms *o*-amido-benzoyl-phenyl-

hydrazine $C_6H_4 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix} + PhNH.NH_2$
 $= C_6H_4(NH_2)CO.NPh.NH_2 + CO_2$.—18. It does not react with boiling di-ethyl-aniline.—19. Pyrocatechin at 130° reacts thus (M. A. B.):

$C_6H_4(OH)_2 + C_6H_4 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$
 $= CO_2 + C_6H_4(NH_2)CO.O.C_6H_3OH$, forming *o*-oxyphenyl *o*-amido-benzoate.—20. Boiled with formic acid it forms formyl-*o*-amido-benzoic acid and a weak base, $C_6H_4N_3O_6$. This crystallises in rhombohedra (from alcohol). It melts at [280°], with decomposition. Sparingly soluble in water, alcohol, benzene, and chloroform. S. (ether) .03 at 15°; S. (alcohol) .11 at 19°. Readily soluble in NaOH, Aq, forming a crystalline salt. Its hydrochloride forms prisms, but is decomposed by water. Heated with conc. HCl at 140° it forms CO_2 , formic acid, and the hydrochloride of anthranilic acid (M. A. B.).—21. By treatment with PCl_5 in presence of $POCl_3$ a product is got whence methyl alcohol and ethyl alcohol respectively form crystalline products. The former gives $C_{10}H_{10}N_2O_4$ [270°]; small needles. The latter gives $C_{12}H_{12}N_2O_5$ [170°]; needles. With conc. HCl at 140° the latter gives EtCl and anthranilic acid (M. A. B.).—22. Bleaching powder suspended in chloroform changes some of the isatoic acid into an isomer [240°], soluble in alcohol, acetone, and benzene. It dissolves in NH_3 Aq without forming anthranilamide (unlike isatoic acid), but when HCl is added to the solution an acid [260°] is ppd. (M. A. B.).—23. Heated with glacial acetic acid and bromine (1 mol.) it forms bromo-isatoic acid, but with more bromine CO_2 is evolved, and di-, tri-, and tetra-bromo-amido-benzoic acids are got.

Chloro-isatoic acid $C_6H_4 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$
 [c. 268°]. From chloro-isatin (10 g.), CrO_3 (20 g.) and glacial acetic acid (120 g.) as described under bromo-isatin (Dorsch, *J. pr.* [2] 33, 49).

Properties.—Pearly plates (from alcohol-ether). Sl. sol. alcohol, acetone, and glacial acetic acid, insol. benzene, chloroform, ether, and water.

Reactions.—1. Conc. HCl forms chloro-*o*-amido-benzoic acid [204°].—2. Hot NH_3 Aq forms the amide of chloro-amido-benzoic acid.

Di-chloro-isatoic acid $C_6H_3Cl_2 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$
 [256°].

Formation.—By oxidation of di-chloro-isatin.

Properties.—Yellow prisms (from alcohol-acetone). Melts at 254°–256° with decomposition. V. sol. acetone and glacial acetic acid, sol. alcohol and chloroform, v. sl. sol. ether and benzene. Boiled with water it partly changes to di-chloro-*o*-amido-benzoic acid, as shown by its violet fluorescence (Dorsch, *J. pr.* [2] 33, 51).

Reactions.—1. Conc. HCl slowly converts it, on boiling, into di-chloro-amido-benzoic acid [224°].—2. With NH_3 Aq it gives di-chloro-amido-benzamide.

Bromo-isatoic acid $C_6H_4Br \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$
 [c. 275°].

Formation.—1. By oxidising bromo-isatin. 2. From Br and isatoic acid suspended in glacial acetic acid at 90° (R. Dorsch, *J. pr.* [2] 33, 32).

Properties.—Pearly plates (from a mixture of alcohol and acetone). Sol. acetone. Sl. sol. alcohol and glacial acetic acid. Insol. water, chloroform, ether, and benzene.

Reactions.—1. With boiling conc. hydrochloric acid it forms (β)-bromo-amido-benzoic acid $C_6H_4Br(NH_2)CO_2H$.—2. With hot NH_3 Aq it gives bromo-amido-benzamide.

Di-bromo-isatoic acid $C_6H_2Br_2 \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$
 [255°].

Obtained by oxidising di-bromo-isatin (10 g.) by CrO_3 (10 g.) in presence of glacial acetic acid (60 g.) as described under bromo-isatin.

Properties.—Flesh-coloured prisms (from alcohol-acetone). Sol. glacial acetic acid and acetone, sl. sol. alcohol, chloroform, and benzene, hardly sol. ether, insol. water. Much more stable than bromo-isatoic acid.

Reactions.—1. Boiled for a long time with conc. HCl it gives off CO_2 , leaving di-bromo-*o*-amido-benzoic acid.—2. It does not dissolve in NH_3 Aq. But if heated with it at 100° for a long time it forms di-bromo-amido-benzamide $C_6H_2Br_2(NH_2)CO.NH_2$ [197°].

Nitro-isatoic acid $C_6H_4(NO_2)NO.CO_2H$
 [220°–230°]. Formed by the action of HNO_3 (S.G. 1.48) on isatoic acid. Insol. water and ether, sl. sol. alcohol. Crystallises from equal parts of alcohol and acetone in pearly plates. It resembles isatoic acid, splitting up readily into CO_2 and nitro-*o*-amido-benzoic acid, when boiled with HCl or even with water. Nitro-isatoic acid is converted by aqueous NH_3 into nitro-amido-benzamide. By Sn and HCl it is reduced to di-amido-benzoic acid, CO_2 escaping. Bromine (in glacial acetic acid) converts it into mono-, di-, and tri-nitro-amido-benzoic acids (q. v.).

Methyl-isatoic acid $C_6H_4Me \begin{matrix} \diagup CO \\ \diagdown N.CO.H \end{matrix}$

Preparation.—Methyl-isatin (10 g.) is mixed with glacial acetic acid (60 g.) and cooled well while a mixture of CrO_3 (21 g.) in glacial acetic acid (60 g.) is slowly added. After 12 hours at 0° the mixture is heated for 2 hours at 40° and then to 70°. It is poured into water containing H_2SO_4 , and the yellow powder crystallised from absolute alcohol (Panaotović, *J. pr.* [2] 31, 123; 33, 58).

Properties.—Pale-yellow crystalline plates

(from boiling alcohol) or trimetric columns (from acetone). At 245° it suddenly increases in bulk, but it melts above 300°, giving off CO₂. V. sl. sol. water, readily sol. boiling alcohol, ether, benzene, and chloroform.

Reactions.—1. Is more stable than isatoic acid, not being decomposed by dilute mineral acids.—2. HNO₃ (S.G. 1.48) dissolves it in the cold. After 12 hours water is slowly added, and the pp. crystallised from benzene. It forms pale-yellow trimetric plates of nitro-methyl-isatoic acid [175°]. This acid is reduced by Sn and HCl to a di-amido-toluic acid.—3. Warmed with HCl (S.G. 1.2), CO₂ is given off, and the hydrochloride of amido-p-toluic acid [207°] formed.—4. Warmed with NH₃Aq it gives the amide of amido-toluic acid [178°].—5. With *aniline* in alcohol it forms the corresponding anilide [243°].—6. With *phenyl-hydrazine* it forms the corresponding hydrazone.—7. With MeOH at 180° it forms methylic amido-toluic acid.

Methyl-isatoic acid C₈H₇NO₃, i.e.

an amido-toluic acid C₈H₇Me(NH₂)CO₂H [5? or 3? : 1 : 2] with chloro-formic ether (Niementowsky a. Rozansky, *B.* 22, 1675). Needles or scales; v. sl. sol. benzene and ether, sl. sol. alcohol. Decomposed on fusion. Acids and alkalis decompose it into CO₂ and amido-toluic acid [177°].

Isomeride of isatoic acid v. ANTHROXANIC ACID.

ISATYDE C₈H₇N₂O₄. Produced by the reduction of isatin by zinc and dilute H₂SO₄ by alcoholic ammonium sulphide, or by zinc-dust and HOAc (Laurent, *A. Ch.* [3] 3, 382; *A.* 72, 285; Erdmann, *J. pr.* 24, 15; 25, 438; Baeyer, *B.* 12, 1809). Formed also by atmospheric oxidation of an aqueous solution of dioxindole (Baeyer a. Knop, *A.* 140, 10). White powder, with slightly greyish tint, almost insol. water, v. sl. sol. boiling alcohol and ether. Separates from boiling alcohol in minute scales. Decomposed by heat, becoming at first violet-brown. Alcoholic potash forms isatic acid, indin, and other products.

Di-chloro-isatyde C₈H₄Cl₂N₂O₄. Formed by the action of ammonium sulphide on chloro-isatin. White powder; crystallisable; insol. cold, v. sl. sol. hot water; m. sol. boiling alcohol, sol. hot aqueous potassium sulphide. At 180° it is resolved into chloro-isatin and chloro-indin. Boiling aqueous or alcoholic potash forms potassium chloro-isatate and the salt C₈H₃Cl(OH).CH(OH).CO₂K.

Tetra-chloro-isatyde C₈H₂Cl₄N₂O₄. Produced by the action of ammonium sulphide on di-chloro-isatin. White powder, in q. l. water. Decomposed by heat into di-chloro-isatin and di-chloro-indin. Alcoholic potash forms di-chloro-isatin and di-chloro-*o*-amido-*o*-oxy-phenyl-acetic (di-chloro-hydrindio) acid.

Tetra-bromo-isatyde C₈H₂Br₄N₂O₄. From di-bromo-isatin and ammonium sulphide. Resolved by heat into di-bromo-isatin and di-bromo-indin.

Thio-isatyde C₈H₇N₂O₃S. Formed by slowly adding alcoholic potash to an alcoholic solution of di-thio-isatyde (Laurent, *A. Ch.* [5] 3, 468).

White crystalline powder. May be crystallised as minute rectangular scales from hot alcohol. Insol. water, v. sl. sol. boiling alcohol and ether. Cold potash forms indin and other products. Hot potash forms the hydride of indin.

Di-thio-isatyde C₈H₇N₂O₂S₂. When H₂S is passed into a conc. alcoholic solution of isatin the liquid becomes pale yellow and on cooling deposits crystals of sulphur and of isatyde. The filtrate when mixed with water deposits di-thio-isatyde (Laurent). Yellowish-grey amorphous powder. Decomposed by heat. Insol. boiling water, v. sol. warm alcohol and ether. Ammonium bisulphite converts it into 'ammonium sulphisatanite' NH₄C₈H₇NSO₄, aq. which crystallises in large pale-yellow tables, v. sol. water, m. sol. alcohol.

Di-bromo-di-thio-isatyde C₈H₄Br₂N₂O₂S₂. Formed together with di-bromo-tri-thio-isatyde, when H₂S is passed into a boiling alcoholic solution of bromo-isatin (Gericke, *Z.* 1867, 895). Yellowish-white powder; insol. hot water, sol. hot alcohol and ether.

Di-bromo-tri-thio-isatyde C₈H₃Br₂N₂O₂S₃. Formed as above. Yellowish-white powder.

Isatane C₈H₇N₂O₃. Formed, as a white pp., when di-thio-isatyde is boiled with a solution of ammonium bisulphite (Laprent, *J. pr.* 28, 346). Formed also by the action of sodium-amalgam on an acid solution of isatin (Knop, *J. pr.* 97, 65). Small white cubes (from ether or hot alcohol); insol. water. Decomposed by hot alcoholic potash into dioxindole and indirubin. Its alcoholic solution gives with ammoniacal AgNO₃ a white pp. of Ag₂C₈H₇N₂O₃.

ISETHIONIC ACID C₂H₃SO₃, i.e.

HO.CH₂.CH₂.SO₃H. *Oxy-ethane sulphonic acid. Sulphonic acid of ethyl alcohol.* Mol. w. 126.

Formation.—1. Discovered by Magnus in 1833 (*P.* 27, 378; *A.* 6, 163) as a product of the action of SO₃ on alcohol or ether. Hence it is found among the residues in the preparation of ether.—2. By boiling ethionic acid with water (Magnus, *A.* 32, 251).—3. By the action of SO₃ on barium ethyl sulphate (Meves, *A.* 148, 196).—4. By the action of nitrous acid on taurine NH₂.CH₂.CH₂.SO₃H (W. Gibbs, *Am. S.* [2] 25, 30).—5. By heating chloro-ethyl-alcohol (chlorhydrin of glycol) with aqueous Na₂SO₃ at 175° (Collmann, *A.* 148, 101).—6. By heating ethylene oxide with aqueous KHSO₄ at 100° (Erlenmeyer a. Darmstädter, *Z.* 1868, 342).—7. Probably formed by boiling ethylene bromide with aqueous Na₂SO₃ (James, *C. J.* 43, 44).—8. By oxidising thio-glycol HO.CH₂.CH₂.SH with nitric acid (Carius, *A.* 124, 266).

Preparation.—SO₃ is added, with shaking, to an equal weight of ether at 0°. As soon as a sample mixed with water gives a heavy oil the whole is poured into water and the ethyl sulphate washed with water till neutral, dried over H₂SO₄, treated with its own weight of SO₃, and then poured into water. The two aqueous liquids are boiled for a long time to decompose ethionic acid, and then neutralised by baric carbonate; on evaporating baric isethionate is got (R. Hüfner, *A.* 223, 212).

Properties.—Viscid, strongly acid syrup, which gradually dries up to a deliquescent radio-crystalline mass. Is not decomposed at 150°, but blackens at a higher temperature. Its

salts are not decomposed by boiling with water, and may even be heated to 200°, above which temperature, however, they lose water and change to di-isethionates. Potash-fusion gives potassium carbonate, oxalate, sulphate, and sulphite. Berthelot (*Z.* 1869, 682) obtained acetylene, K_2SO_4 , and hydrogen. PCl_5 yields $CH_3Cl.CH_2SO_3Cl$, which is converted by heating with aqueous ammonia into taurine (Kolbe, *Z.* 112, 241). Chromic acid oxidises isethionie acid to sulpho-acetic acid $CO_2H.CH_2SO_3H$.

Salts.— NH_4A' : octahedra. [130°] (Streckker); [185°] (Seyberth, *B.* 7, 391). At 235° it changes to ammonium di-isethionate (Carl, *B.* 12, 1604).— KA' : rhomboidal prisms, melting between 300° and 350° without loss of weight. May be crystallised from alcohol.— BaA'_2 : transparent six-sided plates. [320°]. V. sol. water. S. (60 p.p. alcohol) 6 at 14°.— CuA'_2 , 2aq: pale-green prisms.— AgA' : very hygroscopic pearly needles.

Double salts with Et_2SO . (Engelke, *A.* 218, 270). From NaA' , H_2SO_4 , and alcohol, and conversion into barium salt $BaA'_2Et_2SO_4 \cdot 10H_2O$.

Double salt with Me_2SO .— $NaA'Me_2SO$. Silky monoclinic tables (from alcohol), very hygroscopic. Decomposed by water at 80°, thus:

Ethyl derivative $EtO.CH_2.CH_2.SO_3H$. Sulphonic acid of ether. S.G. 21 1.359. The sodium salt is obtained by the action of chloroethane sulphonylchloride on excess of $NaOEt$ (R. Hübner, *A.* 223, 218). Also from $CH_3Cl.CH_2SO_3Na$ and $NaOEt$. The free acid is got by boiling with water the product obtained by acting with H_2S on the (molecular?) compound of its lead salt with lead ethyl sulphate. It is a syrup.

Salts.— NaA' . Plates. S. (alcohol) 2.7 at 15°.— NaA'_3 aq. Columns.— BaA'_2 aq.— ZnA'_2 6aq. Hygroscopic plates.— CuA'_2 6aq.

Double compounds with the salts of ethyl sulphuric acid $EtSO_3H$. Got by adding H_2SO_4 and alcohol to $EtO.CH_2.CH_2SO_3Na$, filtering from Na_2SO_4 , and neutralising with a metallic carbonate. The general formula is: $C_2H_5SO_3H.C_2H_5O.C_2H_5SO_3H$ or $C_2H_5SO_3H.C_2H_5O.C_2H_5SO_3H$, e.g. BaA'_2 aq. Silky scales.— $(NH_4)_2A'_2$ — PbA'_2 — NaA'_2 aq.— ZnA'_2 5aq.— CuA'_2 4aq. These salts are very soluble in water. The free acid splits up on boiling with water, in the following manner: $C_2H_5SO_3H.EtO.C_2H_5SO_3H + H_2O = EtO.C_2H_5SO_3H + H_2SO_4 + EtOH$.

Ethyl ether $HO.CH_2.CH_2.SO_3Et$. From AgA' and EtI (Stampnewsky, *J. R.* 1882, 95).

Ethyl derivative of the ethyl ether $EtO.CH_2.CH_2.SO_3Et$. S.G. 21 1.168. (impure). From $CH_3Cl.CH_2SO_3Cl$ and $NaOEt$ in ether. Not obtained quite pure.

Benzoyl derivative $BzO.CH_2.CH_2.SO_3H$. From potassium isethionate and $BzCl$ (Engelhardt & Latschinnoff, *Z.* 1868, 235).— KA' : Leaflets; v. sol. boiling water; sol. hot alcohol.— BaA'_2 aq: Large thin tables; m. sol. cold water, sol. boiling alcohol.

Chloride $HO.CH_2.CH_2.SO_3Cl$. Probably formed, together with $CH_3Cl.CH_2SO_3H$ and $CH_3CH_2O.SO_3Cl$, by the action of SO_3 on ethyl chloride, or of $ClSO_3H$ on ethylene (Purgold, *B.* 6, 504). Excess of SO_3 converts it into the

chloride of ethionie acid (Claesson, *J. pr.* [2] 19, 258).

Di-isethionie acid $O(CH_2.CH_2.SO_3H)_2$. Di-sulphonic acid of ether. The ammonium salt of this acid is obtained by heating ammonium isethionate to 210° (Carl, *B.* 12, 1604).— $(NH_4)_2A'_2$. [198°]. Slender leaflets of scales; v. e. sol. water.— BaA'_2 aq: prismatic tables. Formed by heating barium isethionate to 200° (Carl, *B.* 14, 65).

ISINGLASS v. PROTEIDS, Appendix C.

ISO. Compounds whose names begin with iso- are usually described either under the name to which iso- has been prefixed or else under their systematic names as described in the *Introduction to Articles Relating to Organic Chemistry*, vol. i.

ISOMERISM. Even a superficial reader of chemical literature will soon become aware that the term *isomeric* and the kindred expressions *allotropic*, *metameric*, and *polymeric* are by no means always used in consistent senses, and he will have considerable difficulty in clearly defining their exact and relative import; it, therefore, appears desirable to discuss the meanings of these terms, especially from the historical side, and as far as possible to define the sense in which they are severally applicable. The following extracts from the article *Isomerism* in the first edition of this Dictionary, vol. iii. p. 416, 1865, by J. A. Wanklyn, serve to show what views were held at the very outset of the period when the investigation of isomeric substances began largely to engage the attention of chemists:—

Isomerism.—This term is derived from *isos*, equal, and *meros* a part, and its employment by chemists is an expression of the fact that very different chemical compounds have sometimes identically the same ultimate composition. Two or more different bodies which are composed of the same elements, and of the same proportions of these elements (*i.e.* which have the same percentage composition) are said to be *isomeric*. Isomerism is sometimes used in a narrower sense, being made to signify equality of molecular weight, as well as identity in percentage composition. When the compounds have the same percentage composition, but different molecular weights, the term *polymeric* is employed. Thus there are the terms *isomeric* (in its wide sense), signifying that the different bodies have the same percentage composition; *polymeric*, signifying that these different bodies have the same percentage composition, but different molecular weights; *isomeric* (in its restricted sense), sometimes called *metameric*, signifying that the bodies have the same percentage composition, and likewise the same molecular weight.

As examples, Wanklyn then cites butyric acid, ethylic acetate, aldehyde, and ethylenic oxide as *isomeric* compounds, using the term in its widest sense: of these butyric acid and ethylic acetate are said to be *polymeric* with aldehyde and ethylenic oxide; butyric acid being *isomeric* (in the restricted sense) or *metameric* with ethylic acetate; aldehyde and ethylenic oxide being also *metameric* compounds. Subsequently, throughout his article, Wanklyn uses the term *isomeric* in its wide sense, substituting the term *metameric* for *isomeric* used in its restricted sense; thus he speaks of methyl, the simplest alcohol radicle, as *metameric* with ethyl hydride (his article was written at a time when Schorlemmer's investigation was not fully recognised as affording proof of their identity); he points out that several *metameric* hexanes are possible; and even quotes 'as a very remarkable

example of metamerism 'the different varieties of tartaric acid and racemic acid.

The term *allotropy* is made use of by Wanklyn in an unusually wide sense. Thus he says:—

'Closely related to the term isomerism is the term *allotropy*. Both of them have reference to the same substantial fact, viz. that different substances have sometimes the same ultimate composition; but they differ in their manner of stating it. Isomerism and allotropy are in fact complementary terms. "Isomerism" being employed to predicate identity of composition between different bodies, whilst "allotropy" expresses difference between bodies of identical composition. Such being the force of these words, there is a certain propriety in their usage; thus, whilst it is correct to say "butyric acid and acetic ether are isomers," it should be "there are allotropic bodies of the formula $C_4H_8O_2$." The same reason which enjoins the use of allotropy in this case prescribes it in the instance of single elements; thus, for example, we read of "allotropic kinds of sulphur," but never of "isomeric kinds." It is worthy of remark that cases of isomerism occurring in inorganic chemistry are usually described by employing the word allotropy or allotropic, while the reverse obtains in organic chemistry. This may be partly ascribed to there being always a very wide difference—or else no difference at all—in the composition of any definite inorganic substances; and hence the fact of identity or non-identity of composition being so easily ascertainable, it is implied in the form of expression, whilst in organic chemistry, the parties alone needs to be made the difference apparent. Among organic bodies, on the other hand, it continually happens that the difference of composition are quite decided, and yet so very minute as to tax the utmost powers of chemical analysis for their recognition; and hence the superior dignity which the mere affirmation of identity of ultimate composition acquires in the organic department of the science. The principal examples of allotropy or isomerism, i.e. of the co-existence of identical ultimate composition with difference of properties, will now be considered.'

He then cites the olefines as examples of polymerism, and afterwards discusses numerous cases of metamerism, several of which were referred to above.

Under the heading *Isomers among Inorganic Substances* the following interesting passages occur at the conclusion of the article:—

'As before remarked, the instances of inorganic isomerism are usually called instances of allotropy—isomeric substances and allotropic substances being nearly equivalent expressions. The elementary substances themselves offer many examples of isomerism. . . . Ozone and oxygen are isomeric bodies. . . . Experiment has shown that the molecular formula for ozone is higher than that for oxygen, but how much higher remains an open question. Sulphur, phosphorus, carbon, and many other elements present somewhat similar examples of allotropy or isomerism. Inorganic compounds, such as the various forms of silicic acid, of sesquioxide of iron, of sesquioxide of chromium, of alumina, must be classed among substances affording examples of isomerism. The explanation of the existence of isomerism will have become sufficiently clear from the course which has been followed in describing the different examples of it. "It is of consequence how the atoms of a compound are arranged, as well as what kind of atoms they are," and hence there may be very many totally different substances composed of the same ultimate atoms. This is in fact the whole philosophy of isomerism.'

The definitions given in Kekulé's *Lehrbuch* (1867) are substantially the same as those adopted by Wanklyn; but he specially draws attention to the existence of compounds *isomeric in a restricted sense*, which, according to the state of knowledge of the time, were to be represented by the same rational formulae, although they either were possessed of different properties—as in the case of the C_4H_8 , hydrocarbons and of maleic and fumaric acids, or they were in all essential respects chemically identical but physically different—such as the tartaric acids, mucic and saccharic acids, &c. The existence of compounds such as these latter, in fact, gave rise to the re-

cognition of a distinct kind of isomerism, termed *physical isomerism*.

In the latest edition of Watts' *Founes* by Tilden (1886), polymerism is included under isomerism, but compounds of the same molecular weight are sub-divided into (1) *metameric* bodies, namely, those which exhibit dissimilar transformations under similar circumstances: propionic acid, methylic acetate, and ethylic formate are quoted as examples; and (2) *isomeric* bodies, *strictly so-called*, namely, those which exhibit the same or closely similar decompositions and transformations when subjected to the action of the same reagents, such as the C_6H_6 , hydrocarbons, the glucoses, the tartaric acids, &c.

It will be noted how incompatible are the definitions given by Wanklyn and in *Founes* of the term *metameric*; it has, however, undoubtedly been customary of late years to employ the term *metameric* in the sense indicated in *Founes*.

In McGowan's translation of Berthsen's *Chemistry* (1889), the most modern book of its kind, polymerism is not reckoned under isomerism, but the definition given of metamerism is on the whole more in agreement with that quoted from Watts' *Founes*; after it has been explained that ethers such as methyl-amy ether, ethyl-butyl ether, and dipropyl ether are isomeric, we read:—

'Such isomerism, which depends upon the grouping together by a polyvalent element of alcohol radicals which are individually unequal, but the sum of whose elements taken together are equal, is called *metamerism*. One of the alcohol radicals may here be replaced by hydrogen. . . . Alcohols and ethers containing an equal number of carbon atoms are therefore *metameric*.'

We further learn that the isomerism of the higher paraffins, since it is based upon the dissimilarity of the carbon chains, is often termed *chain-isomerism*; that the isomerism between ethylene and ethylidene chlorides, or between primary and secondary propyl alcohols, as it depends upon the difference in position of the substituting halogen or hydroxyl in the same carbon chain, is termed *isomerism of place or position*; and that there is the third kind of isomerism, viz. *metamerism*. But obviously two different kinds of relationship are thus included under metamerism; that of position-isomerism, which obtains among the ethers themselves, which are necessarily all compounds of one primary type; and that which obtains between the typically different 'equi-molecular' alcohols and ethers, or, truly metamerism, if the Watts-Founes definition be adopted.

If we consider the origin of the four terms under consideration we find that they were all devised by Berzelius. The term *isomeric* is proposed in his *Jahresbericht*, handed in to the Swedish Academy of Sciences, March 31, 1831 (cf. Wöhler's German translation, 1832, ii. pp. 44-8), in the following words:—

'Da es nothwendig ist, für gegebene Ideen bestimmte, und so viel wie möglich consequent gewählte, Ausdrücke zu besitzen, so habe ich vorgeschlagen, Körper von gleicher Zusammensetzung und ungleichen Eigenschaften (*isomertische*) zu nennen vom griechischen *isomorphos* (aus gleichen Theilen zusammengesetzt).'

In the next volume of his *Jahresbericht* (Wöhler's translation, 1833, p. 68) he gives a

further all-important definition of the case he would make of the term, thus:—

‘Um jedoch nicht Erscheinungen von nicht völlig gleicher Art mit einander zu verwechseln, ist es nothwendig den Begriff vom Worte *Isomerie* genau zu bestimmen. Ich erwähnte dass ich darunter Körper verstehe, die aus einer gleichen absoluten und relativen Atomen-Anzahl derselben Elemente zusammengesetzt sind und gleiches Atomgewicht haben . . . womit nicht der Fall zu verwechseln ist, wo die relative Anzahl der Atome gleich ist, die absolute aber ungleich. So ist z. B. die relative Anzahl von Kohlenstoff- und Wasserstoff-Atomen im gebildeten Gas und im Weiniß absolut gleich; allein in einem Atom vom Gase sind bloss 1 Atom Kohlenstoff und 2 Atome Wasserstoff enthalten, OH_2 , während dagegen im Weiniß 4 Atome Kohlenstoff und 8 Atome Wasserstoff enthalten sind, C_4H_8 . Um diese Art von Gleichheit in der Zusammensetzung, bei Ungleichheiten in den Eigenschaften, bezeichnen zu können, möchte ich für diese Körper die Benennung *polymetrische* (von πολύς mehrere) vorschlagen.’

It will be clear from this quotation, especially from the words which I have italicised, that Berzelius never intended that polymerisms should be regarded as a form of isomerism.

The following passage from the same source clearly exhibits Berzelius's intention as to the use which should be made of the term *isomerie*:—

‘Allein es gibt noch andere Verhältnisse, wo Körper, im eigentlichen Sinne des Wortes, isomerisch scheinen, d. h. dieselbe relative und absolute Atomenanzahl derselben Elemente enthalten können, ohne jedoch vollständig zu sein. Ein solcher Fall ist wenn Körper aus zwei zusammengesetzten Atomen der ersten Ordnung bestehen, die sich auf verschiedene Weise gegen einander umlagern, und in Folge dessen ungleiche Körper bilden können; z. B. $\text{Si}_2\text{O}_3(\text{SnO}_3)_2$, schwefelsaures Zinnoxidyl, und $\text{Si}_2\text{O}_3(\text{SnO}_3)_2$, basisches schwefelsaures Zinnoxid, enthalten eine gleiche absolute und relative Anzahl derselben Elemente, und haben dasselbe Atomgewicht, können jedoch nicht als ein und derselbe Körper betrachtet werden. Bei solchen Körpern ist es der Fall, dass wenn sie eine gewisse Zeit lang bestanden haben, oder wenn die Temperatur geändert wird, eine Umlagerung der Bestandtheile in ihnen vor sich geht, ohne dass etwas hinzukommt oder davon wegeht, und dass dadurch eine anders beschaffene Verbindung entsteht, welche Veränderung nicht selten von einer Temperatur-Erhöhung begleitet ist. Um solche Fälle bestimmt von Isomerie zu unterscheiden, können wir dafür die Bezeichnung *metamerische* Körper gebrauchen (von μετά in derselben Bedeutung wie in Metamorphose).’

Berzelius also cites cyanic and cyanuric acids, which were not then regarded as compounds of different molecular weight, as instances of metameric compounds, regarding the conversion of the latter into the former on heating as a case in which ‘die Cyanursäure von einem zusammengesetzten Atom der ersten Ordnung, oder einem Oxyd eines ternären Radicals, in ein zusammengesetztes Atom der zweiten Ordnung, nämlich in Cyansäure mit chemisch gebundenem Wasser übergeht.’ Cyanuric acid, in which cyanic acid spontaneously changes, and cyanuric acid, in Berzelius's opinion, were (wenigstens vorläufig) isomeric oxides of the same radical.

It is clear therefore that the conception involved in the definition of metamorphism given by Watts & Townes, and in the first edition of this dictionary, is scarcely in conformity with the use of the term by Berzelius; indeed, in 1840 he speaks of ethylic formate and methylic acetate as isomeric. From the example afforded by the two tin compounds, as well as from the explanation given of the nature of the change from cyanuric to cyanic acid, it is to be supposed that the compounds which he intended should be included in the category of metameric substances were such as we should now term *typically different*, and with this conclusion the modern practice is in

Vol. III.

distinct accord; yet the modern and the original application of the term are far from being equivalent, the *meta-* in metamorphosis denoting change: the conversion of the one *metameride* into the other being expressly referred to, it would appear, in fact, that Berzelius distinctly intended to apply the term to those compounds which are capable, in modern phraseology, of undergoing ‘isomeric change,’ and perhaps to these alone.

It was not until 1840 that Berzelius proposed to substitute the term *allotropic* (von ἀλλότροπος welches bedeutet, von ungleicher Beschaffenheit; B. J. 1841: inorg. sec. p. 13) for isomeric, in the cases of the existence of modifications of elementary substances. He appears, however, to have contemplated its extension to compounds, judging from the following passage:—

‘Es kann dann mehr als eine Ursache von dem was wir Isomerie nennen, geben, nämlich (1) Allotropie, wenn nämlich das vorhin angeführte Beispiel von den beiden Schwefelkiesen darauf beruht, dass der eine aus zwei S_2 und der andere S_8 enthält; (2) die ungleiche relative Lage der Atome in der Verbindung . . .; und (3) kann sowohl Allotropie als ungleiche Stellung der Atome in gewissen Verbindungen stattfinden.’

The existence of compounds containing allotropes of one of the constituent elements is distinctly suggested here, but there is nothing to indicate in what way allotropes may be regarded as related; that Berzelius had realised that the relation might be that of polymerides would appear to follow from his reference to Frankenheim's experiments on sulphur, in which it is suggested that the different modifications of sulphur form corresponding gases, and that the dark-yellow gas of sulphur, weighing thrice as much as sulphur gas should accord according to calculation, is not that of the modification occurring in the ordinary sulphur compounds (v. *ALLOTROPY*, vol. i. p. 128: the view here taken is somewhat wider than that adopted by Prof. L. Meyer in that article).

As the term *allotropic* has a general significance, implying only another condition, and involves no assumption either regarding the molecular weights of, or as to the nature of the relationship which obtains between, the allotropes, it may, with great advantage be employed in place of the term isomeric used in a wide sense; this latter term being preferably restricted to those cases in which there is the very closest similarity in structure. Polymerism, metamorphism, and isomerism may in fact all be regarded as varieties of allotropy; there is certainly no reason why carbon compounds should be considered apart from those of other elements, or from elementary substances.

The rational formulæ which are ordinarily made use of are condensed symbolic expressions affording more or less complete information as to the characteristic chemical properties of the compounds which they represent, especially with regard to the manner in which they are formed, and in which they undergo change when submitted to the action of various agents; and equimolecular allotropes which differ either in their mode of formation or in their behaviour under similar circumstances are, as a rule, necessarily represented by different rational formulæ. The formulæ devised for any class of compounds, however, will vary according to the views which

are held as to the valencies of the constituent atoms. At present, formulae are almost invariably constructed on the hypothesis that the several units of affinity—the valencies—of a polyad atom, such as that of carbon, nitrogen, or sulphur, are of the same value and have identical functions; this conclusion being based on the fact that none of the simple derivatives of methane, ammonia, &c., exist in a greater number of modifications than the hypothesis requires. But it cannot be too positively stated that, notwithstanding the extent to which experimental investigation has been carried, we are yet but on the threshold of the temple in which the mysteries of valency are enshrouded. The valency of the hydrogen atom is determined *ex hypothesi* to be unity, and when the facts generally are passed in mental review, it would seem that this conclusion is no mere hypothesis; it is not improbable also that the valencies of the atoms of at least the majority of metallic elements are invariable; but the valencies of the atoms of the non-metals are *apparently* variable. By valency is here understood atom-fixing power.

Most discussions on valency are directed rather than scientific, in consequence of the powerlessness at present to decide what constitutes 'a valency'; the deduction from Faraday's law of electrolysis, to which Helmholtz has directed the attention of chemists (Faraday lect., *O. J. Trans.* 1881, p. 277), that definite, as it were atomic, charges of electricity are associated with the atoms of matter—that a monad bears a single charge, a dyad two, a triad three—is the only approach yet made to a theory of valency, but hitherto chemists have avoided the discussion of the subject from this point of view.

Oxygen and sulphur, nitrogen and phosphorus, carbon and silicon, form gasifiable hydrides, from the composition of which we infer that the atoms of these elements are divalent, trivalent, and tetravalent, respectively; in the case of carbon and silicon there is no reason to suppose that either element ever manifests a higher valency. But both water and ammonia readily combine with other molecules: the formation of such compounds from water is rarely interpreted as evidence of the possession by oxygen of the power of acting as a tetrad; but the water molecule is usually supposed to function in some occult manner as a whole, and to enter into a state of 'molecular combination' different from that of 'atomic combination' in which its constituent atoms exist. The formation of ammonium compounds, however, is more usually regarded as due to the manifestation of a higher degree of valency by the nitrogen. But there is no good reason for explaining the behaviour of oxygen in one way, and that of nitrogen in another.

The question to be decided is, whether a given element may possess two or more degrees of valency; and whether the so-called atomic and molecular forms of combination differ merely in degree and not in kind. Or, to put it in

It appears to me that the term valency must at present be used in a perfectly general sense, and that we cannot restrict our attention to the consideration of gaseous compounds (*v. EQUIVALENCY*): in the case of gases, the problems are for the most part of a very simple kind, and rarely excite differences of opinion; liquids and solids, however, present problems of great complexity.

another way:—is the number of atomic charges associated with a given atom invariable or variable; is it possible for an oxygen or sulphur atom, for example, to carry more than two, or for a nitrogen or phosphorus atom to carry more than three, charges? The writer has endeavoured to explain the exhibition of varying degrees of valency on the assumption that, while the number of charges which any given atom can carry is invariable, a single charge may operate in promoting the union of more than two atoms (*cf. P. M. January 1889*); that in water, for example, the two charges of the oxygen atom are not fully engaged by those of the hydrogen atoms, and that consequently the oxygen atom is still possessed of a certain amount of *residual affinity*. It may be contended that, according to this hypothesis, a compound formed of say trimethylamine and ethyl iodide, $\text{Me}_3\text{N}.\text{IEt}$, would be an allotrope of a compound of ethyl dimethylamine and methyl iodide, $\text{EtMe}_2\text{N}.\text{MeI}$. The most careful experimental study of such compounds (*cf. V. Meyer a. Lecco, Ber. 9, 309, 1866; Burg, Ber. 9, 561, 1864; Klinger a. Claesson, A. 243, 193*) has been made, however, with the result that, in the case of ammonium compounds, it is immaterial in what order or manner the radicles are introduced; and the same is true in the case of sulphine compounds: hence it is supposed that nitrogen has five, and sulphur four, affinities of equal value. But this by no means follows, as the occurrence of 'isomeric change' in such cases is in the highest degree probable—the compound abNid may alone be the stable form into which the allotropes abdNi , acdNi , bcdNi , all spontaneously undergo conversion immediately on formation. There is little doubt that such 'isomeric changes' occur far more frequently than is commonly supposed, and it is most important that the possibility of 'isomeric change' should be very carefully kept in view in determining the constitution of compounds from the study of their behaviour in a limited number of interactions. As valency cannot be determined from any *a priori* considerations, and can only be deduced from the knowledge of the structure of the compounds of the elements whose valency is to be determined, it is obvious that the structure of a substance must be inferred from the widest and most careful study of all its properties: the study of the relationships of allotropic substances is in fact inseparable from that of valency, and the converse is equally true.

In the case of 'unsaturated' carbon compounds, it has been customary of late years to represent the affinities not engaged by other elements as saturating each other: thus, ethylene is formulated as $\text{H}_2\text{C}:\text{CH}_2$; acetylene as $\text{HC}:\text{CH}$. Thomsen's determinations of the heat of combustion of ethylene and acetylene in comparison with those of saturated hydrocarbons, as well as the general behaviour of such unsaturated compounds, may, however, be held to favour the view that the carbon atoms are possessed of free affinities, as expressed by the formulae

$\text{HC}=\text{HC}$. Although the discussion of this question excited considerable attention a few years ago, it has latterly almost entirely fallen into

oblivion, but as very many of the cases of anomalous isomerism, of which an explanation is required, occur among compounds of the ethylenic type, it is one of considerable importance. The possibility of the two forms of combination pictured by the expressions

should also be taken into account, especially in the case of ethylenic derivatives.

Among the more recondite problems of valency requiring mention is that relating to the number of carbon atoms which form closed chains or rings. It is now regarded as well established that, in addition to the six-atom ring of benzene, five-atom rings also exist; indeed, their formation apparently takes place with peculiar readiness; the existence of both three- and four-atom rings is now also generally held to be established, chiefly in consequence of the researches of W. H. Perkin, jun. (cf. *Notes Trans.* 1885, 801, *et seq.*). The hydrocarbon obtained by the action of sodium on trimethylene bromide, $\text{BrCH}_2\text{CH}_2\text{CH}_2\text{Br}$, is almost universally assumed to be the simplest compound of the kind, trimethylene, $\text{H}_2\text{C} \begin{array}{c} \text{H}_2\text{C} \\ | \\ \text{H}_2\text{C} \end{array} \text{CH}_2$; as shown by

Freund, its discoverer, this hydrocarbon has the remarkable property of being readily absorbed by a solution of hydrogen iodide, forming normal propyl iodide, although it is acted on with extreme slowness by bromine. By the action of ethylenic bromide on the disodium derivative of ethylic malonate, Perkin has obtained an acid which he regards as a trimethylenedicarboxylic acid $\text{H}_2\text{C} \begin{array}{c} \text{H}_2\text{C} \\ | \\ \text{H}_2\text{C} \end{array} \text{C}(\text{COOH})_2$; and by employing trimethylenic bromide in place of ethylenic bromide, he has prepared what he regards as tetramethylenedicarboxylic acid

closely resemble the hydrocarbon in their behaviour with bromine and halohydrates. The easy resolution of closed carbon chains by halohydrates in this manner, however, is altogether without precedent in the case of five- and six-atom carbon rings, at all events, which, as a rule, cannot be split by means of halohydrates, but are frequently resolvable by bromine; their behaviour is more nearly akin to that of five-atom rings such as those of furfuran and indole, which also resist the action of bromine, but are resolvable by treatment with agents which are commonly regarded as weaker than bromine (the formation of pyridine derivatives from pyrrole and of quinoline derivatives from indole, which appears to involve the resolution at some stage of the operation of the five-atom rings, is contemplated in this statement). The alternative formula for trimethylene, if it be not a closed chain hydrocarbon, is $\text{CH}_2\text{CH}_2\text{CH}_2$, which represents it as a compound in which two terminal carbon atoms are each possessed of a single free affinity; the possibility of the existence of such compounds has not yet been contemplated by chemists, excepting myself. It is conceivable, I think, that such a compound would be attacked by bromine with difficulty, in consequence of the two un-

satisfied carbon atoms failing to assist each other in separating the constituent atoms of the bromine molecule and the impossibility of a 'conducting chain of molecules' being formed between the carbon atoms, as bromine is a dielectric; as solutions of the halohydrates are electrolytes of low resistance, such a conducting chain might, however, be formed in their case, and the requisite electrolysis of the halohydrate molecule could thus occur. According to Thomsen, trimethylene has a higher heat of combustion than propylene, $\text{CH}_3\text{CH}=\text{CH}_2$; judging from the analogy afforded by benzenoid compounds, it is to be expected, however, that the closure of the chain involved in the formation of the three-atom ring would be attended with a considerable loss of energy, and that propylene would, therefore, have the higher heat of combustion: its behaviour with bromine certainly justifies this view. The confirmation of Thomsen's statement thus becomes of extreme importance. It is a noteworthy fact that ethylenic oxide, according to Thomsen, also has an exceptional heat of formation, and that this observation has proposed to represent it as a dimethylenic oxide of the formula CH_2OCH_2 . Ethylenic oxide as represented by the conventional formula bears a similar relation to trimethylene that furfuran bears to pentamethylene, thus

Thomsen's formula for ethylenic oxide is inadmissible, as it indicates a severance of the carbon atoms. If, however, the formula were written $\text{CH}_2\text{CH}_2\text{O}$, it would correspond to that given above to trimethylene; Thomsen's observations that both ethylenic oxide and trimethylene have an exceptional heat of combustion may therefore be regarded as mutually confirmatory. It is also to be noticed that the compound formed from ethylenic bromide and a sulphide is not the corresponding sulphide, but the polymeride thereof

be assigned to trimethylene, Perkin's tri- and tetramethylene derivatives must also be represented by open chain formulae. Perkin has fully discussed this question, and has pointed out the improbability attaching to such formulae. The evidence does not appear to be sufficient, however, to permit of a final decision being arrived at with regard to so difficult a question.

Finally, it is necessary to refer to a problem closely akin to the two previously considered, viz. that relating to the distribution of the spare affinities of the carbon atoms in closed chains; of those affinities, that is to say, which are not engaged in the formation of the ring, or in retaining the hydrogen atoms. This problem is chiefly of importance in discussing the structure of benzenoid hydrocarbons and their derivatives. Of the various formulae proposed for benzene, that of Kekulé always has been, and still remains, the most popular; but it is open to the serious objection that it represents benzene as a compound containing three pairs of carbon atoms in the same condition as the pair in ethylene. Dewar's for-

mula is open to a similar objection. The prism formula of Ladenburg and the diagonal formula of Claus cannot be objected to on this ground, but are open to criticism in many other respects, and in the light of Von Baeyer's recent researches on the reduction products of terephthalic acid (cf. A. 245, 103; 251, 257) these formulae are generally regarded as finally disposed of (cf. Miller, *C. S. Trans.* 1887, 208).^c A symbol proposed by the writer in February 1887 (cf. *P. M.*), and a year later also by Von Baeyer (A. 245, 122), appears to be exempt from the deficiencies which characterise previous formulae; but it embodies somewhat unconventional conceptions, and therefore has not yet attracted attention. The

symbol in question  has been very happily

termed the *centric* formula by Von Baeyer; he expressly states that this formula is to be understood to indicate that 'die 6 Kohlenstoffvalenzen des Benzols sich sättigen, ohne dadurch drei Verkettungen der Kohlenstoffatome zu bewirken' (A. 251, 285)—one valency of each atom directed towards the centre of the ring, and the six valencies mutually paralyse each other (A. 251, 122). My own words were: 'Of the twenty-four affinities of the six carbon atoms twelve are engaged in the formation of the six-carbon ring, while the remaining six react upon each other, acting towards a centre as it were, so that the affinity may be said to be uniformly and symmetrically distributed. . . I do not consider that, apart from its connexion with the other carbon atoms owing to their association in the ring, any one carbon atom is directly connected with any other atom not contiguous to it in the ring. . . each individual carbon atom exercises an influence upon each and every other carbon atom. . . there is an excess of affinity beyond what is required to maintain the C_6H_6 ring; but I do not consider that each carbon atom can be considered to have an affinity free.'

The conclusion here arrived at with regard to benzene, that no direct connexion exists between any but the contiguous carbon atoms in the ring—that para-carbon atoms are not and cannot become united—may be regarded as of universal application. Von Baeyer's experiments prove, moreover, that the dihydro-terephthalic acid in which an atom of hydrogen is associated with each of the para-carbon atoms to which the carboxyls are attached, unlike terephthalic acid, behaves as an unsaturated compound, forming a tetrabromide, and that it is to

be represented by the formula . From

this it follows that the type changes on conversion of the 'centric' compound into the di-addition compound, and probably this is generally the case; for example, when quinol is converted into

It would also follow that in the case of benzenoid compounds four of the six 'spare' affinities cannot act 'centrically.' To what extent this is true in the case of other rings remains to be ascertained; from the remarkable similarity of thiophene and benzene, it would appear probable that the former is to be represented as analogous to

the analogous compounds furfuran and pyrrole more nearly resemble the unsaturated compounds in their behaviour; but this is perhaps ascribable to the influence exercised by the oxygen or imidogen.

The foregoing brief discussion will suffice to direct attention to the numerous problems comprised in the philosophy of isomerism, and to show how far from final are the conclusions as to structure which we are at present able to arrive at.

In a large and rapidly increasing number of instances, it is impossible to assign different rational formulae to compounds undoubtedly different so long as the system employed takes into account merely the nature of the radicles and the manner in which they are associated as pictured by disposing them in a single plane. If, while assuming the hydrogen atoms in a compound, such as methane—in other words the four valencies of the carbon atom—to be equal, it be supposed that the radicles introduced in place of the hydrogen atoms occupy relatively different positions in the plane, a variety of isomeric derivatives would appear to be possible: e.g. two of the form $CR_1R_2R_3R_4$, two of the form $CR_1R_2R_3R_4$, and three of the form $CR_1R_2R_3R_4$; R_1, R_2, R_3, R_4 being different radicles. A special study of methane derivatives from this point of view has been made by Henry, but both his results and our general experience show that isomerides such as are here contemplated do not occur.

By considering the arrangement of the atoms in space, conclusions have, however, been arrived at which are far more in harmony with experience. Such a step was first taken in 1874 by Van't Hoff (*La Chimie dans l'Espace*, Rotterdam, 1875), and independently and almost simultaneously by Le Bel (*Bl.* [2] 22, 337; cf. *ibid.* 23, 295). A German adaptation of Van't Hoff's pamphlet entitled, *Die Lagerung der Atome im Raume*, was published in 1877 by Hermann. A full account of the subject is to be found in the previous edition of this dictionary and in Miller's 'Chemistry,' vol. iii.

The fundamental hypothesis of the Van't Hoff system consists, as is well known, in supposing that the carbon atom occupies the centre of a tetrahedron and that its four affinities are directed towards the four solid angles. When four different radicles are associated with the carbon atom, but only in such a case, two isomerides are possible, represented by two irregular non-superposable tetrahedra bearing to each other the relation of an object to its reflected image; and, moreover, these isomerides should be of enantiomorphous crystalline form, as

well as optically active and possessed of equal and opposite rotatory powers, as the molecules are unsymmetrical, such tetrahedra exhibiting, in relation to an axis drawn parallel to the corresponding edges, a screw-shaped grouping of the four summits, turning to the right in the one form and to the left in the other. A carbon atom thus situated is termed *asymmetric*, and is represented in a formula by an italicised *C*. The hypothesis serves therefore at once to explain both the existence of isomerides which cannot be represented by formulae written in a single plane, and to account for the optical activity of certain substances. Thus in the case of tartaric acid, which contains two asymmetric carbon atoms, but is composed of two equal groups, $(\text{COOH})(\text{HO})\text{HC}.\text{CH}(\text{OH})(\text{COOH})$, the hypothesis indicates the existence of two optically active isomerides of equal but opposite rotatory powers, and a third inactive isomeride in which the optical effect of the one asymmetric carbon atom is balanced and neutralised by the equal opposite effect of the other; it thus accounts for the existence of *dextro*-, *levo*-, and *meso*-tartaric acids; racemic acid, the fourth modification, apparently, is to be regarded as a 'physical' allotrope formed by the conjunction of the two active isomerides: it would seem that it does not exist in solution. Van't Hoff has shown, in a recent much extended new edition of his pamphlet, that every provision of the hypothesis with reference to the optical characters of isomerides has been fulfilled in the most complete manner possible by the investigations carried out in the interval since its enunciation by Le Bel and himself (cf. *Dix Années dans l'Histoire d'une Théorie*, Rotterdam, P. M. Bazendijk, 1887); this remarkable agreement of practice with theory has naturally led to the almost universal adoption of the hypothesis.

The hypothesis also provides for a greater number of isomerides in the case of compounds of the ethylenic type than is indicated if the space relationship of the radicles be omitted from consideration; if a compound of the form $\text{R}_1\text{R}_2\text{C}:\text{CR}_3\text{R}_4$ be represented by two tetrahedra joined so as to have one edge in common, it will be found that only one such figure can be constructed, if either the four radicles are identical, or if only R_1 differs from R_2 , or R_3 from R_4 ; but if R_1 is different from R_2 , and R_3 is also different from R_4 , although R_1 and R_3 , R_2 and R_4 are identical, two such figures may be constructed—this is more readily rendered obvious by the adoption of the simpler plan of writing the symbols of the radicles attached to the two doubly-linked carbon atoms on either side of a line representing the plane of their conjunction.

Thus the symbols $\frac{a}{b}$ and $\frac{a}{b}$ represent modifications in which in the one case the two similar radicles are situated symmetrically with reference to a plane at right angles to the axis of the system, and in the other are symmetrically situated with reference to the axis of the system; such modifications may therefore be termed, as Wislicenus has suggested, the *plane* and *axially* symmetric modifications. The isomerism of maleic and fumaric acids is regarded by Van't

Hoff as dependent on such a difference in structure.

Such a *stereometric* mode of formulation does not afford an increased number of expressions for acetylenic derivatives; the same is true of benzenoid compounds if Kekulé's symbol be adopted (cf. Marsh, *P. M. Nov.* 1888, p. 426). It may be noted, however, that the asymmetric carbon atom hypothesis is applicable to the explanation of the optical activity manifested by a variety of closed chain compounds, such as quercitol and quinic acid, which are derivatives of hexamethylene, and conine and its homologues, which are derivatives of piperidine.

Although the Van't Hoff-Le Bel hypothesis has been very generally accepted as affording a sufficient explanation of a very large number of cases of isomerism difficult to account for in accordance with the existing canons of belief, it is as yet by no means certain that it can be always so regarded; in many cases the difference between isomerides is so great that it is somewhat difficult to believe that it depends on so comparatively simple a difference in structure as the presence of one or more asymmetric carbon atoms would involve. The two isomerides tartaric acids are the veritable image the one of the other; but this is rarely the case; thus hydrobenzoin differs very considerably from isohydrobenzoin, and also mannitol and dulcitol, and to a still greater extent the acids, saccharic and mucic, formed from these latter; in all these cases the isomerism is assumed to depend on mere geometrical differences. In the case of meso- and racemic tartaric acids, the intra-molecular neutralisation of one asymmetric carbon atom by the other already produces the marked effect, as evidenced by the difference in properties of this acid in comparison with either of the active modifications. It may be, therefore, that in the case of mannitol and dulcitol, and the acids formed by their oxidation, the accumulated effect of the several asymmetric carbon atoms is much greater than in the case of tartaric acid, and hence the greater difference in properties between the isomerides. Very little alteration is involved in the formation of racemic acid, and, as above pointed out, this substance appears to be a mere 'physical' allotrope, hardly a polymeride, of its active constituents; in certain cases the formation of the 'racemic form' is attended with a considerable alteration in properties—in the case of leucine and of camphoric acid, for example, their racemic forms being much less soluble and of higher melting-points than their optically active constituents. In these cases there would seem to be a more intimate union than in the case of racemic acid; the marked difference between saccharic and mucic acid may be due to some such cause as this. But the isomerism of the hydrobenzoin is more difficult to explain, assuming that they are both compounds of the formula $(\text{C}_6\text{H}_5)(\text{HO})\text{HC}.\text{C}(\text{OH})(\text{H})\text{C}_6\text{H}_5$. Including a racemic form, four modifications of such a compound appear possible, two of which should be optically active. Neither compound is optically active, and, judging from Zincke's observations, it does not appear probable that, if the one be the meso or inactive modification corresponding to meso-tartaric acid, the other is, the racemic form. The assumption that the one, perhaps

isohydrobenzoin, contains the two hydroxyl-groups attached to the one carbon atom, thus $C_6H_5.H.C(OH).C_6H_5$, would satisfactorily account for its behaviour, but has hitherto been rejected as improbable owing to the general belief that compounds of such a character are excessively unstable. But it may be that the presence of the negative phenyl groups confers stability in such a case, much as in the case of chloral hydrate; and it is well to remember that in not a few instances of late years proof has been given of the incorrectness of views based on general considerations, as in the case of phthalic chloride, for example, and the hydroxamic acids.

Still greater difficulties occur in accepting the conclusion that the Van't Hoff hypothesis affords an explanation of the isomerism of unsaturated compounds such as maleic and fumaric acids, which, according to this view, are respectively the plane symmetric and axially symmetric isomerides of the formula

It is well known how great are the differences between these two acids, both in physical properties and in general chemical behaviour: that maleic acid alone yields a corresponding anhydride, fumaric acid being converted into the same anhydride when dehydrated. Ostwald also has shown that the electrical conductivity of their solutions is such as to indicate that maleic acid is a weak acid akin to selenious and phosphorous acids, whereas fumaric acid is a well-marked dibasic acid (*J. pr. F.* 332). Maleic acid has also a considerably greater heat of combustion than fumaric acid (Thomsen, *J. pr.* 40, 202). Roser has suggested that, whereas fumaric acid is a normal di-carboxylic acid, maleic acid is to be represented by the formula

This formula would afford a satisfactory explanation of the great differences observed between the two acids, and it has been strongly advocated by Anschütz (*A.* 254, 168). No valid argument has yet been advanced which would prevent its adoption.

It may here be pointed out that no attention is paid in applying the Van't Hoff hypothesis to unsaturated compounds to the peculiarities which are manifest in such compounds, and which apparently must be attributed to the presence of unsaturated carbon atoms; a 'double or ethylenic bond' is represented as the precise equivalent of two single bonds, and a 'treble or acetylenic bond' as the equivalent of three single bonds, which is certainly not in accordance with facts, and especially with Thomsen's observations on the heats of combustion of unsaturated compounds.

Wislicenus has not only accepted the Van't Hoff-Le Bel hypothesis in its entirety, but has in the most ingenious manner possible extended its application, and has endeavoured both to elucidate the structure of geometrically isomeric unsaturated compounds, and to explain the 'isomeric changes' which such compounds frequently exhibit (*Abhandlungen der math. phys. Klasse*

der Königl. Sächsischen Ges. der Wissenschaften, Band xiv. Leipzig, 1887).

In the case of maleic and fumaric acid—assuming that these are stereometric isomerides—as pointed out originally by Van't Hoff, the formula

HOOC.CH may without hesitation be

assigned to the latter, as it is incapable of forming an anhydride, whereas maleic acid, being easily convertible into the anhydride, is represented by the formula

HC.COOH ; in the case of crotonic and isocrotonic acids, however, it is more difficult to find criteria on which to base a choice between the formulae

and similarly in other cases. Wislicenus considers that if a compound of the form $C_2R_2R_2R_2$, consisting of the two systems $R_2R_2C=$ and $=CR_2R_2$, be derivable from a corresponding acetylenic compound, its constitution can at once be inferred from the fact that when one pair of bonds between the carbon atoms in the acetylenic compound is severed, as the two atoms are still united by double bonds, no rotation of the system can take place; consequently the added radicles both occupy positions on one side of the common axis of the systems. Thus the tolane dichloride melting at 143° , obtained by chlorinating tolane, is necessarily the plane symmetric modification:

The isomeride of lower melting-point (63°) must therefore be regarded as the axially symmetric compound

$\text{Cl.C}_6\text{H}_5$. In principle this method appears perfectly sound, but it is based on an assumption with reference to the manner in which the carbon atoms in ethylenic and acetylenic compounds are united, which, as previously pointed out, is perhaps open to question; it also involves the conclusion that the radicles attached to the carbon atoms are incapable of changing their positions, which is also by no means a safe assumption, bearing in mind the extreme readiness with which 'isomeric changes' occur.

A method of more universal application, but involving much more complex considerations, is the following. In saturated compounds in which the carbon atoms are united by single affinities, one carbon system must be capable of rotating about another; moreover, it is to be assumed that the atoms in a molecule—even those which are not directly connected—exercise an influence on each other, and will therefore tend to condition such rotation so that radicles which have the greatest affinity are brought into the closest proximity possible. Thus, on converting ethylene into its chloride, in the first instance the change would take place in accordance with the following scheme:

But, in consequence of the superior affinity of hydrogen for chlorine, such a system would be unstable, rotation would set in, and the more

stable system $\begin{array}{c} \text{CHHCl} \\ | \\ \text{COHH} \end{array}$ would result.

To take another case, that of the conversion of tolane tetrachloride into dichloride by reduction; this compound may present three configurations, viz.:

It would probably chiefly consist, especially at low temperatures, of the second and third modifications, as the dissimilar radicles are most proximately situated in these; and as these two modifications would both furnish the axially symmetric dichloride on reduction, it is to be supposed that the chief product of reduction will be this dichloride; actually that melting at 68° is chiefly obtained (Blank, A. 248, 1), and it is, therefore, to be supposed that this modification is axially symmetric—a conclusion which harmonises with that previously arrived at.

To this it may be objected that our knowledge of the relative affinities of the radicles within a compound is surely hypothetical; and that it is by no means certain that dissimilar radicles would in all cases tend to influence and attract each other more than would similar radicles. Thomsen's observations on the heats of combustion of chlorine compounds, in fact, would appear to favour an opposite conclusion. But a more important argument is to be found in the fact that in cases in which the constitution may fairly be regarded as established, the relation is of the obverse order to that required if the contention of Wislicenus be correct: thus, the symmetric or para-derivative of benzene always has the highest melting-point; the same appears to be true of the symmetric tri- and tetra-derivatives; and, in the case of naphthalene, the axially symmetric isomeride is always that of highest melting-point (*cf.* *J. S. Proc.* 1888, 93).

Another use which Wislicenus has made of the argument here criticised may now be mentioned. It is a well-known fact that maleic acid is very readily converted into fumaric by the action of acids. Wislicenus supposes that when this conversion is effected, for example, by bromhydric acid, the double bond becomes severed, bromosuccinic acid being formed:

but rotation setting in, the radicles are brought into their preferential positions, viz.:

HC.BrCOOH , and when, by the action of the water present, this modification becomes deprived of hydrogen bromide, fumaric acid naturally results. Although in the highest degree ingenious, this conception unfortunately does not appear to be in accordance with the facts, for, as Anschütz points out (*ib.* 254, 168), the conversion takes place under conditions under which the succinic derivative is stable, and there is no reason therefore to suppose that such a compound is formed at any stage of the conversion of maleic into fumaric acid; if maleic acid be formulated in the manner advocated by An-

schütz, its conversion into fumaric acid by acids is easily understood.

Victor Meyer's researches have led him to carry speculation even further. On submitting benzil to the action of hydroxylamine, Meyer and Goldschmidt obtained an α -dihydroxime which they found was converted into a more stable β -isomeride by heating with alcohol to about 180° ; a careful investigation of these compounds was subsequently made by Meyer and Auwers, but they were unable to discover any substantial difference in their chemical behaviour, and they came to the conclusion that both must be regarded as compounds of one and the same formula $\text{C}_6\text{H}_5\text{C(N.OH).C(N.OH).C}_6\text{H}_5$. As the existence of two such compounds was incompatible with the assumption that carbon atoms united by single affinities are free to rotate, Meyer and Riecke (*B.* 21, 946) have put forward an hypothesis as to the nature of the carbon atom itself which serves to account for two kinds of union by single affinities, one in which rotation is impossible, the other in which it can freely take place. Having regard, however, to the readiness with which 'isomeric change' takes place, and to the extremely imperfect state of our knowledge of the exact manner in which polyad elements are held in association, there cannot be any doubt that it is premature to conclude that the benzil dihydroximes are necessarily structurally identical; the study of chemical interchanges is after all but an approximate and fallible mode of determining structure.

Hantzsch and Werner (*Ber.* 23, 11) have quite recently proposed to extend the Van't Hoff conception to the nitrogen atom itself. They suppose that in some nitrogen compounds the three affinities of the nitrogen atom are directed towards three of the solid angles of an irregular tetrahedron, and that the nitrogen atom itself is located at the fourth. In the case of compounds of the form CXY.NZ , which are comparable with carbon compounds of the form CXY.OHZ , it is conceivable that the Z radicle may alter its position in space relatively to the radicles X and Y, and thus give rise to isomerides.

Victor Meyer (*B.* 23, 567) has, however, pointed out that the views of Hantzsch and Werner are in many respects in conflict with the experimental evidence. This memoir is a noteworthy contribution to the discussion of a number of the more obscure cases of isomerism. (The two papers here referred to have been published since this article was in type.)

It is here the place to refer to the numerous discussions which have taken place during late years in cases in which one set of interactions of a compound appear to be in accordance with one formula, while another set favour a different but closely related formula, which have led, in fact, to the recognition of labile or pseudo-forms capable of passing spontaneously into stable forms. For example, it has long been a question whether ethylic acetoacetate is to be represented as $\text{CH}_3\text{CO.OH.C}_2\text{O.Et}$ or by the formula $\text{CH}_3\text{C(OH).CH.CO.Et}$. A discussion of such cases has been given by Laar (*B.* 18, 648; 19, 780), who proposes to term such isomerides *tautomeric*. But, as he practically himself admits, the use of such a term savours of tauto-

logy. V. Meyer subsequently brought forward a suggestion of Jacobson's to substitute *desmotropic* for tautomerism. Hantzsch and Herrmann (B. 20, 2801), while using the term tautomerism when speaking of compounds capable of passing from the one type into the other, proposed to limit the term desmotropic to each of the states. As the phenomena in question are the outcome of mobility and not of fixity, the new term also appears to be particularly ill chosen, and bearing in mind the intention of Berzelius in introducing the term metameric (see p. 81), it would appear that this old term is a peculiarly appropriate one to use in such cases. Laar suggests that a compound which is capable of an 'alternative' behaviour actually has an alternating structure, the intra-molecular condition being such that the structure is of one kind at one moment and different at another. But, as Hantzsch and Herrmann remark, it is scarcely necessary to make such an assumption. Ethylic succinylsuccinate and its derivatives manifest the peculiarity in question in a high degree, acting sometimes as quinonic compounds and sometimes as quinols, i.e. in modes such as correspond to the presence of one or other of the two forms $\text{CO.CH}(\text{CO}_2\text{Et})$ and $\text{C}(\text{OH})_2\text{C}(\text{CO}_2\text{Et})_2$. As a rule only one of the forms is stable, the other being developed in the course of the change; thus phloroglucol appears to be a true trihydroxybenzene, i.e. a phenol; but frequently it affords derivatives of 'triketohexamethylene,' which may with propriety be termed phloroglucone. Thus

Phloroglucol.

Phloroglucone.

It is not improbable that in those cases in which the several forms can be obtained in a definite crystalline form, the necessary stability is conferred by union of the fundamental molecules amongst themselves. The formation of such molecular complexes is rendered probable by a large number of observations; one of the most striking is that recently brought forward by Perkin in the case of orthomethoxybenzaldehyde $\text{CH}_3\text{O.C}_6\text{H}_4\text{COH}$ (C. J. Trans. 1889, 549), which is capable of existing in two solid modifications, one unstable melting at 3° , the other stable and melting at 35.5° . A list of similar cases of what is sometimes termed *physical isomerism* is quoted by Perkin.

Having thus briefly touched on the numerous problems which the study of the different kinds of *allotropism* presents, it appears desirable finally to re-direct attention to the terminology of the subject.

The term *allotropic*, as already pointed out, has a perfectly general meaning and is therefore applicable to the phenomena generally, and may be used in all cases in which the nature of the relationship is obscure.

According to our modern conceptions, truly isomeric substances—substances composed of equal parts—are equi-molecular compounds containing identical radicles arranged in relatively

different modes, and on the principle of calling a spade a spade, bearing in mind that it was obviously the intention of Berzelius to limit the scope of the expression, the term *isomeric* should be used only with reference to such compounds. The space relationship of the radicles being the determining cause of isomerism, although it is not always requisite in order that it may become apparent to express their relationship according to stereometric canons, it is scarcely necessary to make any principal distinction between cases, such, for example, as occur among benzene derivatives and between the tartaric acids; but if it be thought desirable to call attention in some way to the finer isomerism which obtains in cases such as the latter, the term *eikotism*, from *eikón*, a likeness or image, may be suggested as not inappropriate.

Typically different allotropes belonging to different classes of compounds might well be termed *heteromeric*, metameric being reserved for those heteromeric allotropes which change their type with exceptional facility in the course of chemical interchanges; but if the use of the term in this restricted sense be objected to, such allotropes might advantageously be spoken of as *isodynamic*. Allotropes belonging to the same class but consisting of different radicles—the butylic alcohols, for example—might be termed *isomeric*. It appears unnecessary to specially distinguish the physical isomerism manifest in the occurrence of several crystalline forms of different melting-point. The phenomena of polymorphism generally, as well as those involved in change of state from solid to liquid and gas, and the existence of allotropic forms both of the metallic and non-metallic elements, are now being more and more generally attributed to changes in molecular complexity; and if this be the case, such allotropes mostly partake of the nature of polymeric allotropes.

H. E. A.

ISOMORPHISM (*Isos*, equal to; *μορφή*, form). In the year 1819 Mitscherlich (A. Ch. [2] 14, 172) discovered that certain arsenates and phosphates of analogous constitution crystallised in the same form; subsequent investigation (A. Ch. [2] 19, 350; 24, 264, 355) led to the general conclusion that substances of analogous chemical constitution possess the same or nearly the same crystalline forms, and will under suitable conditions crystallise together in all proportions to form homogeneous mixed crystals; such substances are termed *isomorphous*. In spite of numerous attempts to widen or otherwise modify it, this definition has lasted to the present time. Owing, however, to recent researches, especially those of Groth, it will be best not to treat isomorphism as an isolated phenomenon, but as a part of that branch of physical chemistry which studies the relations between the chemical composition and crystalline form of bodies, and which from a knowledge of the constitution and chemical properties of a substance seeks to predict its system, form, and crystallographic constants. We are still very far indeed from doing anything approaching to this, for, although attempts have not been wanting—v. Schrauf (Physikalische Mineralogie, 1866, bd. 2, 166; Z. K., 9, 265) and Barlow (C. N. 58, 8, 16)—small success has so far attended them,

and at present crystal-form cannot be deduced from a knowledge of chemical constitution and properties alone; if, however, we find that in a given case certain atoms arranged in a certain definite way are accompanied by a certain definite form, we may argue that similar atoms similarly arranged will be accompanied by a similar form. This hypothesis is found to be true, and its verification has resulted in the discovery of relations between the forms of substances more or less chemically allied. These relations may be conveniently discussed under the three following heads:—

I. The same chemical substance possesses two or more forms—*Polymorphism*.

II. Bodies more, or less closely related chemically have more or less analogous forms—*Morphotropy*, including *Isomorphism*.

III. Bodies not chemically related possess the same form—*Isogonism*.

Full references, especially for the early history of the subject, will be found in the article *Isomorphie*, by Arrau, in Fehling's *Handwörterbuch der Chemie*, 1873, vol. 3; for more recent work Fock's *Einführung in die Chemische Crystallographie*, Leipzig, 1888, may be consulted; while full lists of substances considered isomorphous have been given by Topsøe, *Tidsskrift for Physik og Chemi*, 8, 6, 193, 321; 9, 225; summarised by Arrau above. For the use of isomorphism in determining atomic weights v. ATOMIC AND MOLECULAR WEIGHTS, vol. I. p. 336.

POLYMORPHISM. Häuy believed that every substance possessed its own characteristic form, and, in spite of numerous observations tending to establish the chemical identity of calcite and aragonite (v. De Lisle, Klapproth, Thenard, and Stromeyer), refused to admit that the same substance could yield two distinct kinds of crystals. In the course of the work on the arsenates and phosphates which led him to announce that two different chemical compounds could possess the same or nearly the same crystalline form, Mitscherlich found that $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ gave, according to the conditions, two kinds of crystals, while his discovery in 1823 (*A. Ch.* [2] 24, 264) that sulphur crystallised both in rhombic and oblique forms readily convertible the one into the other by change of temperature alone, established conclusively that the same substance could exist in two different forms; to express these phenomena Mitscherlich proposed the term *dimorphism*, and in 1828 recognised the possibility of *trimorphism*. The existence of several modifications of the same substance may be generally expressed by the terms *polymorphism* or *heteromorphism*. At the present time these terms are usually applied to compounds only, polymorphism, when exhibited by elements, being termed *allotropy* (q. v., vol. i. p. 128). The change of one dimorphous modification into another has been especially studied by Lehmann, and all known cases have been collected and discussed by him in his *Molekularphysik*, 2 vols. Leipzig, 1888 (vol. i. pp. 119–219, vol. ii. pp. 398–415).

MORPHOTROPY. From the time of Mitscherlich onwards the rapid growth of organic chemistry provided a large number of new substances for crystallographic examination, and as the existence of many cases of isomorphism among inorganic substances had been established, numerous attempts were made to introduce the same conception into organic chemistry.

In general, however, these efforts were fruitless, and the researches merely resulted in the introduction of new terms and in several attempts at widening Mitscherlich's definition.

Thus Laurent, who investigated the halogen substitution and addition products of naphthalene and salts of the fatty acids, concluded that identity of system is not necessary for isomorphism. Nicklès and De la Provostaye collected cases of analogous angles and introduced new terms, such as hemi-isomorphism, isomorphism, and hemimorphism, to express those cases in which crystals of two substances had each a zone with nearly similar angles (v. papers by these authors, *C. R.* 11, 15, 20, 23, 26, 27, 29). Pasteur again (*C. R.* 26, 535) found analogies between the tartrates, while other workers in the same direction were Rammelsberg, Marignac, Delafosse, Sella, and Hjortdahl (*J. pr.* 94, 286). Owing to the paucity of results, such researches lost favour till Groth, in 1871 (*P.* 141, 181; *B.* 3, 449), attacked the subject from a new point of view, and set himself to investigate the changes in crystal-form which take place when one or more of the hydrogen atoms of an organic molecule, such as benzene, are substituted by other atoms or groups. The relations observed between the form of the parent substance and the form of the substituted body Groth terms morphotropic relations, while he attributes the actual change of form produced by substitution to the morphotropic force of the elementary atom or group. Benzene, which crystallises in rhombic pyramids, was the first substance examined by Groth; he compared its form with the forms of as many as possible of its hydroxy-, nitro-, amido-, and haloid, substitution products, and his researches have led to the following general statement. The less the chemical character of the combination is changed by substitution the less is also the change of crystal-form, which depends

1. On the specific morphotropic properties of the substituting atom or group;
2. On the chemical nature and crystalline system of the body in which substitution occurs;
3. On the relative positions of the substituting atoms or groups in the molecule.

1. Morphotropic properties of atoms and groups.

(a.) The metals. Potassium and ammonium, when substituted for H, only change one axis, thus:—

Picric acid	rhombic	$\frac{a}{b}$	$\frac{c}{c}$
Potassium picrate	"	0.937 : 1	0.974
		0.942 : 1	1.0552

As a rule, all the alkali metals produce the same effect.

(b.) Substitution of OH for H in benzene derivatives only alters the crystalline form slightly, and in rhombic substances the ratios of two of the axes remain unaltered, and only the third axis is materially affected.

NO_2 and NH_2 behave much like OH.

Benzene	rhombic	$\frac{a}{b}$	$\frac{c}{c}$
Resorcin	"	0.931 : 1	0.799
Nitrophenol 1:2	"	0.910 : 1	0.540
Dinitrophenol 1:2	"	0.878 : 1	0.6007
Trinitrophenol 1:2:4:6	"	0.938 : 1	0.753
		0.937 : 1	0.974

(c) Cl, Br, and I act more energetically, but less regularly, than NO_2 . The angles of one zone, however, remain like those of the parent substance, while the system is generally altered to one of lower symmetry.

Benzene . . . rhombic 110 : 110 = 96° 30'
Dichlorobenzene oblique " " 98° 40'
Tetrachlorobenzene " " 96° 17'

(d) The influence of the CH_3 group is extremely variable, depending very much on the nature of the substance into which it enters. Among the substituted ammonias it is often without influence; thus, $2\text{NH}_4\text{Cl.PtCl}_6$, $2\text{NH}(\text{CH}_3)_2\text{Cl.PtCl}_6$, $2\text{N}(\text{CH}_3)_3\text{Cl.PtCl}_6$, all crystallise in the cubic system.

2. Influence of the nature of the parent substance. When the parent substance belongs to the cubic system, substitution has either no influence on the form, or else causes change to a system of lower symmetry. In other systems the axial ratios may alone alter, or the system itself may be changed, according to the morphotropic force of the substituting element or group. If the hydrogen atoms of like functions are replaced singly the system frequently at first changes to one of lower symmetry, but when the substitution is complete returns to the symmetry of the parent substance. The methyl substitution compounds of $2\text{NH}_4\text{Cl.PtCl}_6$ illustrate this well:—

$2\text{NH}_4\text{Cl.PtCl}_6$. . . Cubic
$2\text{NH}_3(\text{CH}_3)\text{Cl.PtCl}_6$. . . Rhombohedral
$2\text{NH}_2(\text{CH}_3)_2\text{Cl.PtCl}_6$. . . Rhombic
$2\text{N}(\text{CH}_3)_3\text{Cl.PtCl}_6$. . . Cubic
$2\text{N}(\text{CH}_3)_3\text{Cl.PtCl}_6$. . . Cubic

As an illustration of the influence of the chemical nature of the parent substance, we may quote the observation of Hintze that, contrary to the general rule, the substitution of the paraffinoid H in $(\text{C}_2\text{H}_5)_2\text{CH}$ by (OH) or Br raises the symmetry, instead of lowering it.

3. Influence of position.—The relative position of the substituting atoms in the molecule has a very great influence on the form of the crystal; but we are very far from being able to connect form and constitution.

As a rule the crystals of isomerides exhibit very few analogies, and in many cases none at all. In the benzene series, however, a few relations have been observed, though even here they are rare, and often more readily detected by a comparison of the isomerides with the parent substance than directly with each other. Thus a comparison of the angles given by Bodewig (P. 158, 232) for the three dinitrobenzenes shows that certain analogies do exist, although the compounds do not crystallise in the same system, while *meta*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$ is related to benzene itself, as is shown in the following table:—

C_6H_6	rhombic 0.881 : 1 : 0.799
<i>o</i> - $\text{C}_6\text{H}_4(\text{NO}_2)_2$	oblique 0.8112 : 1 : 0.6735 $\beta = 67^\circ 55'$
<i>m</i> - $\text{C}_6\text{H}_4(\text{NO}_2)_2$	rhombic 0.9430 : 1 : 0.8384
<i>p</i> - $\text{C}_6\text{H}_4(\text{NO}_2)_2$	oblique 0.8883 : 1 : 1.0483 $\beta = 87^\circ 45'$

The above examples suffice to show very clearly that the great influence exercised by position renders the discovery of the morphotropic properties of an element or group very difficult. Thus we have stated above that the entry of the nitro-group into benzene leaves the

system and axial ratio $a:b$ unaltered, while the c axis is more or less changed. This statement we found held good for *o*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$, *o*- $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ (1:2:4), *o*- $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$ (1:2:4:6), and *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$. As soon, however, as we become acquainted with *o*- and *p*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$, the generality of our statement disappears, and the exact morphotropic value of the NO_2 group remains still undetermined. Although we are not in a position to deduce form from a knowledge of constitution alone, we may often from the chemical analogy of two substances, the form of one of which is known, draw conclusions as to the form of the other; or, *vice versa*, knowing the form of two substances, and the constitution of one of them, we may draw conclusions as to the constitution of the other. This method has been chiefly employed in inorganic chemistry, but Friedländer (Z. K. 8, 168) has made use of it in order to throw light on the constitution of the trinitrobenzene got by nitrating *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$. The trinitrobenzene made in this way may be either of three theoretically possible ones. It crystallises, however, in the rhombic system, and has the axial ratios 0.954 : 1 : 0.733, and agrees accordingly with *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$. On the other hand it shows little or no analogy to the forms of *o*- or *p*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$, and it is therefore probable that this substance is symmetrical trinitrobenzene 1:3:5. A comparison of its form with that of picric acid $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ (1:3:5:6), rhombic 0.937 : 1 : 0.974, confirms this view.

ISOMORPHOTROPY AND ISOMORPHISM. When the products obtained by replacing the hydrogen atoms of the parent substance by two closely-allied atoms or groups are compared together they are often found to crystallise in identical or nearly identical forms; such products are isomorphous, while the substituting atoms or groups are said to possess the same morphotropic force, or to be isomorphotropic. Thus, K and NH₄ are isomorphotropic, and replace the H of acids to give isomorphous salts.

The term morphotropy was first applied to cases in which an atom of H was substituted, but the conception may very conveniently be extended to include all cases of substitution whatever; thus, KBr may be regarded as derived from KCl by substituting Br by Cl, and since KCl and KBr both crystallise in the same system and possess very similar physical characters, they are isomorphous, while Cl and Br are isomorphotropic. The greater the analogies between the substituting atoms the greater is the correspondence between the forms of their compounds, i.e. the more closely isomorphous are they; but because two elements are isomorphotropic when in combination with one set of atoms or groups it does not necessarily follow that they are always isomorphotropic, for the morphotropic force of any atom is largely conditioned by the compounds in which it finds itself. Again, Kopp (P. 53, 446) has pointed out that although it is often true that two isomorphous substances combine with a third to form two isomorphous compounds (Schröder), we cannot, as has been too frequently done, deduce the isomorphism of elements from the isomorphism of their compounds; there are few elements which cannot by such a mode of reasoning be made isomorphous. Elements are only truly isomorphous when they

forms, if they merely combine with another element or group to form isomorphous compounds they may be spoken of as isomorphotropic in that particular class of compounds. As we have seen, the conception of morphotropy includes that of isomorphism. Now, ever since the latter term was introduced, great difficulties have been felt in defining it, and in finding tests which might authoritatively decide in any given case whether two substances were isomorphous or not. Mitscherlich's definition is vague, for we at once ask, What constitutes chemical analogy? And again, How widely may the angles of two substances differ and the substances still be considered isomorphous? The truth seems to be that no hard and fast line can be drawn between those substances which are so closely related morphotropically as to be considered undoubtedly isomorphous, and those slightly less closely related whose isomorphism is doubtful; while we may pass by imperceptible stages from truly isomorphous bodies to others to which, although they still exhibit relations, this term is as evidently inapplicable. Although it seems impossible in the present state of our knowledge to give a definition which shall distinctly mark off isomorphous bodies from those which are merely closely related morphotropically, this is not in practice attended with any very great inconvenience, for the difficulty is chiefly one of nomenclature; most cases of isomorphism are at once recognised as such, and it is only in comparatively few instances that we must hesitate.

In doubtful cases much assistance may often be obtained by a comparison of the other properties of the two substances. Besides great similarity of form, agreement in several other physical properties has been thought necessary before two substances could be considered isomorphous; and we must now notice in detail the more important of these properties, pointing out the weight which has been attached to each as a test of isomorphism.

Physical properties of isomorphous substances.

(a.) *Geometrical properties.* As the name itself implies, near equality of external form is the first and most essential condition for isomorphism. Absolute geometrical isomorphism, however, does not exist except in the case of substances crystallising in the cubic system; in all other systems small differences of angle occur, a fact first noticed by Wollaston. These differences are seldom equally distributed; in rhombic oblique and triclinic crystals the anomalies are often confined to one zone, another zone perpendicular to the first having the same angles in both cases. Here a difficulty meets us, for we ask, How great may these differences become and the substances still remain isomorphous? Unfortunately no definite answer to this question is possible; some authors have admitted much wider differences than others, while others still have gone so far as to admit that the boundaries of the systems may be overstepped. It is perhaps best to restrict the term isomorphous to substances crystallising in the same system with nearly the same angles. It is to be noted that though all substances crystallising in the cubic system have exactly the same angles

they are not necessarily isomorphous; to be so they must be either both holohedral or must both possess the same kind of hemihedrism, and must also agree in other properties, such as cleavage and power of forming mixed crystals.

(b.) *Cleavage.* Isomorphous bodies possess as a rule the same cleavages: variations in the relative perfection of such cleavages are, however, possible. This property is especially useful in assisting us to detect isomorphism in the cubic system.

(c.) *Thermal conductivity.* Jannettaz (*O. R.* 75, 1501) has shown that certain isomorphous substances have axes of maximum and minimum conductivity of like direction and magnitude.

(d.) *Coefficient of expansion.* The data are not sufficient for general conclusions to be drawn, and no simple relations have been detected at present.

(e.) *Etched figures.* Since these stand in a close relation to crystalline form, Baumhauer has sought to use them as a test of isomorphism. He finds that isomorphous substances give, as a rule, the same sort of etched figures, but that they often differ in orientation.

(f.) *Optical properties.* These have been specially compared by Senarmont (*A. Ch.* [8] 83, 391), Topsoe, and Christiansen (*A. Ch.* [5] 1, 5). No general law has been established, but as a rule isomorphous bodies if uniaxial have the same sign of double refraction, and if biaxial have the plane of the optic axes similarly oriented, but biaxial crystals, oblique and triclinic ones especially, exhibit frequent exceptions. Optical properties are, moreover, very sensitive to changes of temperature, which often do not influence isomorphous substances to the same degree (Arzruni, *Z. K.* 1, 165).

(g.) *Specific volume.* The relations between chemical composition, S.V., and crystalline form are of special importance, since several authors have considered near equality of S.V. an essential condition for isomorphism. The first of these was Kopp (*A.* 36, 1; *P.* 47, 138; 52, 243, 262; 53, 446), his views may be briefly summarised as follows: (1) The condition for isomorphism is equality or near equality of S.V. The answer to the question, how widely may the S.V.'s differ and the substances remain isomorphous, is given by the empirical formula

$$D = \frac{v - v_1}{\frac{1}{2}(v + v_1)}, \text{ where } v \text{ and } v_1 \text{ are the S.V.'s of the}$$

two substances. If $D=0$ the isomorphism is perfect, but if D is greater than .33 the substances are not isomorphous; thus the value of D for the two substances ZnCO_3 and CaCO_3 , whose S.V.'s are 28.2 and 36.8 respectively, is .264; they are, therefore, isomorphous. (2) Kopp has also pointed out that the nearer are the axial ratios of a series of isomorphous bodies the nearer are their S.V.'s. This statement, though criticised by Schröder, appears to hold good, and has received the support of Tschermak (*Sitz. W.* 45 [2] 603) and Schrauf (*P.* 184, 417). The former expresses the law as follows: 'The series of crystal-dimensions and specific volumes is in each group of isomorphous bodies of analogous composition the same.' As an illustration he gives the series of rhombohedral carbonates:

ISOMORPHISM.

	$a : d$	
ZnCO ₃	1 : 0.807	28.2?
MgCO ₃	1 : 0.812	27.9
(MgFe)CO ₃	1 : 0.814	29.2
FeCO ₃	1 : 0.819	30.2
MnCO ₃	1 : 0.822	31.9
CaCO ₃	1 : 0.854	36.8

Schröder (P. 50, 553; 95, 441, 562; 106, 226; 107, 113) at first held views much resembling those of Kopp, but in his later papers he comes to the conclusion that the statements made above are erroneous, and expresses himself thus: 'The specific volumes of isomorphous compounds differ in general quite as much from one another as the specific volumes of corresponding heteromorphous compounds' (Schröder uses the term heteromorphous as opposed to isomorphous, it is now often considered synonymous with polymorphous), and he believes that his results lead him to a new law, viz. 'If two elements or groups, A and B, enter into combination with other elements or groups C, D, E, &c., to form the compounds A C and B C, A D and B D, A E and B E, &c., belonging to the same type and isomorphous by pairs, then the differences of the specific volumes of A C and B C, A D and B D, A E and B E, are always equal.' If, however, the pairs of compounds are not isomorphous, or if the isomorphous pairs belong to different types, the differences are as a rule unequal. Schröder terms bodies of equal S.V. *isosteric*, and the equality of the differences of analogous pairs *paralleloterism*. Adopting this nomenclature, the above law may be shortly expressed thus: 'Isomorphous analogous pairs of like type are also paralleloteristic.'

Tschermak (l.c.) finds that, although Schröder's criticism of Kopp is unfounded, his own results support Schröder's law, which he enunciates thus: 'Among isomorphous bodies a like difference of composition corresponds to a like difference of specific volume;' thus the difference Br - Cl is about equal to 6.3.

S.V.	S.V.	S.V.	S.V.
NaBr 33.4	KBr 44.3	AgBr 31.8	AmBr 42.2
NH ₄ Cl 27.2	KCl 37.9	AgCl 26.0	AmCl 35.2
6.2	6.4	5.8	7.0

Apparent exceptions to Schröder's law are believed by Tschermak to be due to difference of constitution in the substances compared, and he illustrates this by the following table of difference for the change of composition K to Am:

S.V.	S.V.
KCl 37.9	KBr 44.3
AmCl 35.2	AmBr 42.2
2.7	2.1
S.V.	S.V.
K ₂ PtCl ₆ 134.5	K ₂ SO ₄ 65.6
Am ₂ PtCl ₆ 150.5	Am ₂ SO ₄ 74.6
16.0	9.0

We see from this table that substances of the type M₂PtCl₆ cannot be directly compared with those of the type M₂SO₄, or these again with M₂O.

Tschermak has, moreover, endeavoured to trace a connection between the varying differences shown by pairs of elements which occur

in compounds of similar constitution, and the crystal-system to which these compounds belong.

Cubic	S.V.	Oblique	S.V.
Am ₂ PtCl ₆	150.5	Am ₂ Cu(SO ₄) ₂ .6aq	218
K ₂ PtCl ₆	134.5	K ₂ Cu(SO ₄) ₂ .6aq	205
	16.0		13
Am ₂ IrCl ₆	156	Am ₂ Mg(SO ₄) ₂ .6aq	209
K ₂ IrCl ₆	138.3	K ₂ Mg(SO ₄) ₂ .6aq	196
	17.7		13
Tetragonal			
Am ₂ CuCl ₄ .2aq	137	Am ₂ Fe(SO ₄) ₂ .6aq	212
K ₂ CuCl ₄ .2aq	133	K ₂ Fe(SO ₄) ₂ .6aq	197
	4		15
Rhombic			
Am ₂ SO ₄	74.6	Am ₂ Zn(SO ₄) ₂ .6aq	211
K ₂ SO ₄	65.6	K ₂ Zn(SO ₄) ₂ .6aq	201
	9.0		10

Thus he finds that for the change of composition Am₂ to K₂, the difference of S.V. is greatest in the cubic system, less in the oblique, still less in the rhombic, and least in the tetragonal system.

In connexion with S.V. we may note that at or about maximum and minimum points of the atomic volume curve (v. PEARSON'S LAW) occur ductile metals crystallising in the cubic system, e.g. Na, Mg, Al, K, Fe, Co, Ni, Cu, Pd, Ag, Pt, Ir, Au, Hg, Pb.

Although isomorphism is usually accompanied by similar values for the S.V.'s, we cannot from the near equality of S.V. alone deduce the isomorphism of two substances, neither can we at the present time attach much weight to Kopp's empirical formula as a test of isomorphism; in a general way, however, his results, in common with those of Tschermak, Schröder, and Schrauf appear to hold good; owing, however, to the great discrepancies which exist between the relative densities of many of the commonest substances as given by different observers, we must be cautious in accepting conclusions often resting on doubtful data.

Special properties of isomorphous substances.

(a.) *Formation of layer-crystals.*

(b.) *Formation of mixed crystals.*

(c.) *Layer-crystals.* These are made by growing a crystal of one substance in a solution of another.

Kopp (B. 15, 1653) considers regular growth under these circumstances the best test of isomorphism.

Thus a crystal of common alum when brought into a solution of chrome alum continues to increase regularly; again the sulphates of the type M''SO₄.7aq where M'' = Zn, Mg, Fe, Co, Ni, grow in solutions of one another.

In those cases where the forms of the two substances are the same the new particles have exactly the same orientation as those of the nucleus. Klocke (Z. K. 2, 144) has, however, brought to light differences between the phenomena of growth in such cases, and in those where a crystal grows in its own solution. Having produced etched figures on the faces of two potassium alum crystals, he grew one in its

own solution, the other in a solution of ammonia iron alum; in the first, case the etched figures were rapidly filled up from the bottom, in the second very much flattened octahedra of ammonia iron alum were developed at certain points on the crystal of common alum, and perfectly parallel to it, they then increased laterally, and covered up the etched figures, which remained unaltered till the new layer reached them.

Although the power of forming overgrowths seems to be a necessary consequence of isomorphism, the property is not confined to isomorphous substances alone, and from the perfect conformity of form and orientation exhibited by isomorphous substances, such as the alums, we may pass by imperceptible stages to cases of regular orientation among substances possessing but little chemical analogy and crystallising in different systems. Thus rutile TiO_2 , tetragonal, is often found developed on the basal plane of hæmatite Fe_2O_3 , rhombohedral, in such a way that the c axis of the rutile lies in a plane of symmetry of the hæmatite.

A specially interesting and much discussed case of overgrowth is that of calcite CaCO_3 , rhombohedral $rr' = 74^\circ 55'$ and NaNO_3 , rhombohedral $rr' = 73^\circ 27'$. When a rhombohedron of CaCO_3 is placed in a solution of NaNO_3 , this substance is deposited on the former in small rhombohedra, whose morphological axis and planes of symmetry are exactly parallel to those of the CaCO_3 , these rhombohedra grow till they meet, a polysynthetic crystal being the result. Kopp accordingly made a difference between growth in this case and the regular increase of alum crystals; in the light of Klocke's work, and taking into consideration the slight difference of the angles rr' , such a distinction vanishes, and if the formation of overgrowths is a test of isomorphism, these two substances are certainly isomorphous, a view confirmed by the agreement in their other physical characters; the difference in their chemical constitution leads us rather to regard them as an example of isogonism.

Closely connected with the formation of layer-crystals are Thomson's researches on supersaturated solutions (*C. J.* 1879, 196); he has shown that supersaturated solutions of certain salts can readily be crystallised by the addition of crystals of isomorphous salts, while crystals of substances not possessing the same form, or fragments of amorphous bodies, such as glass, have no influence. Thus a supersaturated solution of $\text{MgSO}_4 \cdot 7\text{aq}$ is at once crystallised by $\text{ZnSO}_4 \cdot 7\text{aq}$, $\text{NiSO}_4 \cdot 7\text{aq}$, and also by $\text{CoSO}_4 \cdot 7\text{aq}$ and $\text{FeSO}_4 \cdot 7\text{aq}$, whose action, however, is less rapid; on the other hand, $\text{Na}_2\text{SO}_4 \cdot 10\text{aq}$, NaCl , and glass, are quite inactive. Common alum can be crystallised by iron and chrome alums, while other cubic substances, such as NaCl , FeS_2 , and Fe_2O_3 , are inactive.

This appears to be an excellent test of isomorphism as far as it goes, but it is unfortunately of very limited application.

Although at the present time the formation of layer-crystals cannot be considered a conclusive proof of isomorphism, the success or failure of attempts to obtain them may help us to determine whether two substances crystallising in the cubic system are isomorphous or not.

(A discussion of numerous cases of layer-crystallisation will be found in Lehmann's *Molekularphysik*, Bd. i. pp. 393-407; v. also Wackernagel, *Künstlers Archiv*, 5, 293, and especially Kopp, *B.* 12, 901.)

(b) *Mixed crystals.* To obtain mixed crystals solutions of two substances are mixed, or in some cases the two substances are simply melted together, and then allowed to crystallise; we thus obtain perfectly homogeneous crystals, which do not, however, contain their components in any fixed ratio.

As a rule only isomorphous substances yield mixed crystals, and their formation is usually considered the best criterion of isomorphism. (Klein (*C. R.* 95, 781), Kopp (*B.* 12, 863; 17, 1105), but v. also Bruegelmann (*B.* 17, 2359), and especially Lehmann (*Lc.* Bd. i. 420, 456, 461).)

Numerous researches have been undertaken with a view to the elucidation of the constitution and mode of formation of mixed crystals, while other investigators have endeavoured to trace the connexion between their physical properties and those of their components.

Growth of mixed crystals. Mixed crystals are most readily formed when the two substances have nearly equal solubility, and in this case Rammelsberg (*P.* 91, 321), has found that the ratio of the two salts in the mixed crystal is about the same as in the solution, mixed crystals of $\text{ZnSO}_4 \cdot 7\text{aq}$ and $\text{MgSO}_4 \cdot 7\text{aq}$ afford a case in point; if, however, as more usually happens, the solubilities differ, the first crystals always contain most of the less soluble salt, the last most of the more soluble; such salts are $\text{CuSO}_4 \cdot 5\text{aq}$ and $\text{MnSO}_4 \cdot 5\text{aq}$. Thomson (*Lc.*) has pointed out that in the case of the crystallisation of supersaturated solutions, consisting of a mixture of two substances, the composition of the mixed crystal depends very much on the velocity of crystallisation; if this takes place suddenly the composition of the mixed crystal is much the same as that of the solution, if slowly the less soluble salt is deposited first.

The physical properties of mixed crystals.

(a) *Geometrical properties.* Mixed crystals belong to the same system as their components, but exhibit simpler forms; cf. calcite and dolomite, and v. also Rammelsberg (*Lc.*). In some cases the angles of mixed crystals lie between those of their components, this usually holds good for the naturally occurring mixtures of the rhombohedral carbonates, thus:

Chalybite FeCO_3	$rr' = 72^\circ 59'$
Pistomesite $(\text{FeMg})\text{CO}_3$	$= 72^\circ 42'$
Magnesite MgCO_3	$= 72^\circ 33'$

But even in this series exceptions are not wanting, and as a rule no simple relation can be detected between the angles of the mixed crystals and those of its components; thus Groth (*P.* 188, 193) in the case of the permanganates and perchlorates found that the angles of the mixed crystals often lay outside those of their components.

	KClO_4 , rhombic	$\bar{b} : \bar{a} : \bar{c}$
K	$\left\{ \begin{smallmatrix} \text{Mn} \\ \text{Cl} \end{smallmatrix} \right\} \text{O}_4$	$0.7819:1.0:0.6396$
K	$\left\{ \begin{smallmatrix} \text{Mn} \\ \text{Cl} \end{smallmatrix} \right\} \text{O}_4$	$0.7797:1.0:0.6408$
K	$\left\{ \begin{smallmatrix} \text{Mn} \\ \text{Cl} \end{smallmatrix} \right\} \text{O}_4$	$0.7839:1.0:0.6398$
	KMnO_4	$0.7974:1.0:0.6493$

In the crystal containing 1Mn:11Cl the ratio lies inside the limits, and the other two outside; further increase in the quantity of Mn causes the form of the mixed crystal to approach nearer to that of KClO_4 . Similar results have been obtained by Arzruni on baryto-celestine (*Min. Mit.* 1875, 59), v. Lang on Am_2SO_4 and K_2SO_4 (*Sitzb.* 1858, 81, 85), Arzruni and Baerwald on compounds of FeS , and FeAs , (*Z. K.* 7, 337), and lastly by Miers in his investigations of proustite and pyrrargyrite (*Min. Mag.* 8, 37).

(b.) Optical properties.

(i.) Index of refraction. In the year 1878 Dufet (*C. R.* 86, 881), from an investigation of $\text{MgSO}_4 \cdot 7\text{aq}$, $\text{NiSO}_4 \cdot 7\text{aq}$, and $\text{ZnSO}_4 \cdot 7\text{aq}$, found that the connection between the chemical composition of isomorphous mixtures and their indices of refraction is one of simple proportionality, so that expressing the results graphically by taking, along two axes at right angles, ordinates proportional to the observed values of μ , and abscissae proportional to the percentage of one component in the mixture, the resulting curve is a straight line. Fock (*Z. K.* 4, 583) has, however, taken exception to Dufet's work, and although he finds that the changes in the values of the ordinary and extraordinary ray are proportional to the changes in composition for mixed crystals of $\text{SrSO}_4 \cdot 4\text{aq}$ and $\text{PbSO}_4 \cdot 4\text{aq}$, yet in mixtures of thallium and potassium alums, and again in mixtures of $\text{MgSO}_4 \cdot 7\text{aq}$ and $\text{MgCrO}_4 \cdot 7\text{aq}$, he could find no such law; v. also Fitz and Sansoni (*Z. K.* 6, 67). Fock's results have in their turn been questioned by Soret (*Z. K.* 11, 197) and Dufet (*C. R.* 99, 990). The former finds that mixtures of thallium and potassium alum and also of ammonium and potassium alum satisfy the law, while the latter has shown that mixtures of $\text{MgCrO}_4 \cdot 7\text{aq}$ and $\text{MgSO}_4 \cdot 7\text{aq}$ are not sufficiently homogeneous for investigations of this kind.

Dufet's law probably holds good, but further investigation is needed before it can be considered established.

(ii.) Optic axis angle. Wyruboff (*Bull. Soc. Min. France*, 2, 91, 170) has endeavoured to trace the connection between the angle of the optic axis and the chemical composition in the cases of mixtures of K_2SO_4 and Am_2SO_4 , and of K_2CrO_4 and K_2SO_4 . His results have been expressed graphically by Mallard (*Bull. Soc. Min. France*, 3, 8), who finds that they give a continuous regular curve, not, however, a straight line. If the optical properties of the components are non-accordant, those of the mixed crystals will be different from either; v. especially Senarmont (*l.c.*) on mixed crystals of $\text{KNaH}_2\text{C}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$ and $(\text{NH}_4)\text{NaH}_2\text{C}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$ —

	Optic axis plane	1st mean line	2nd mean line
Potassium salt	010	a	c
Ammonium	100	c	b

Starting from the potassium salt and substituting with NH_4 , we observe the following changes; first the obtuse angle diminishes, and more quickly for red than for violet light, then at a certain point the axes for red light coincide, while the axes for violet light still lie in Q10, the red axes then begin to diverge in 100, the violet

afterwards coincide and follow the red. Wyruboff (*Z. K.* 13, 349), on ammonium and thallium tartrates, gives the following example:—

	Optic axis plane	2H
Ammonium salt	b	42° 58'
Thallium	100 b	59° 30'

The mixture had always the cleavage and optic axis plane of the ammonium salt, and a crystal containing 88.7 p.c. of the thallium salt had $2\text{H} = 48^\circ 80'$.

(iii.) Circular polarisation. Bodländer (*Z. K.* 9, 809) investigated mixtures of lead and strontium thiosulphates; he found that the rotation varied directly with the composition.

(iv.) Angle of extinction. Max Schuster has shown that the angle of extinction of certain oblique and triclinic mixed crystals, especially the feldspars, varies directly with their chemical composition. His results have been confirmed by Mallard (*Z. K.* 6, 612), who has treated the subject mathematically.

(v.) Specific volume relations. The specific volumes of mixed crystals appear to depend directly on the relative proportions of their compounds. Thus Schröder states (*P.* 95, 441) that

$$V(a\text{CaCO}_3 + b\text{FeCO}_3) = \frac{aV'(\text{CaCO}_3) + bV''(\text{FeCO}_3)}{a+b}$$

where V is the specific volume of the mixed crystal and V', V'' are those of its components. These results have been confirmed by Tschermak (*l.c.*) thus:

BaCO_3 (witherite) rhombic	V = 45.7
CaCO_3 (aragonite) rhombic	38.9
$\therefore (\text{BaCa})\text{CO}_3$	39.8
while alstonite rhombic	39.5

The specific volumes of artificial mixed crystals have been especially investigated by Betgers (*Z. P. C.* 3, 497). He has studied with great care the mixed crystals formed by (a) K_2SO_4 and Am_2SO_4 , (b) potassium and thallium alums; he finds that the S.G. varies directly with the composition, and expressing his results graphically he obtains as his curve a straight line, a result similar to that obtained by Dufet for the values of μ .

Formation of mixed crystals by isodimorphous substances.—Two substances, X and Y, are said to be isodimorphous if they each exist in two forms A and B, A' and B', of which A is isomorphous with A' and B with B'.

On crystallising a solution containing two isodimorphous substances two series of mixed crystals are obtained, one set having the form A, the other the form B. It often happens that the form A of one salt, X say, is stable under ordinary circumstances, while of the other salt, Y, the form B is stable; in the mixed crystals of the form A the substance X predominates, in mixed crystals of the form B, Y is present in excess. In such cases as these a continuous series of mixed crystals cannot always be obtained. Crystallisation under these conditions has been especially studied by Rammelsberg (*P.* 91, 321). Thus he finds that $\text{MgSO}_4 \cdot 7\text{aq}$ is rhombic and $\text{FeSO}_4 \cdot 7\text{aq}$ is oblique; from a solution containing both substances two sorts of mixed crystals are obtained, these do not, however, contain their constituents in all possible proportions, but a gap

occurs, the oblique crystals always having more than 1 atom Fe to 2.3 Mg, while the rhombic crystals always contain more than 4 Mg to 1 Fe. Another good example is afforded by BeSO_4 , 4aq tetragonal and BeSeO_4 , 4aq rhombic. The mixed crystals are tetragonal when $\text{S:Se} > 7.33:1$, and rhombic when $\text{S:Se} < 4:1$ (Topsoe, *Sits. W.* [2] 66; v. also Schulze, *A.* 125, 49; Wyruboff, *Bull. Soc. Min. France*, 2, 91).

Cases of crystallisation perfectly analogous to but differing from these have been studied by Rammelsberg (*l.c.*); thus copper sulphate usually crystallises in the triclinic system with 5aq, ferrous sulphate in the oblique system with 7aq. When solutions of copper sulphate and ferrous sulphate are mixed and allowed to crystallise, two sorts of crystals are got, both of which contain Cu and Fe; as long as the proportion Cu:Fe is $> 20:1$ the crystals possess 5aq and are triclinic, but when there is less Cu the crystals are oblique and contain 7aq.

It is very commonly supposed, when two substances closely allied chemically crystallise in different forms but yield two kinds of mixed crystals, that these substances are isodimorphous, although more than one form of each may not be known; v. Fock (*Z.* K. 6, 160), and note the adverse criticism of Wyruboff (*Bull. Soc. Min.* 5, 32).

The specific volumes of isodimorphous substances have been compared by Rideal (*B.* 19, 589); while Retgers (*l.c.*) has found that in those cases where isodimorphous substances form mixed crystals, each series obeys the law enunciated above, viz. that the relative density varies directly with the composition.

Constitution of mixed crystals.—Since the beginning of the century two opposing views have been held as regards the constitution of these substances.

(a.) According to the first or physical theory, as we may call it, the most homogeneous mixed crystal really consists of a very intimate mixture of particles of each of the components. This view, held by Haidy, and maintained by Frankenheim in opposition to Berthollet, has recently received the support of Lehmann and Retgers; the latter says that a mixed crystal is a very intimate but purely mechanical mixture of its components, and finds strong confirmation of his view in the fact that the densities, indices of refraction, &c., of mixed crystals vary directly with their composition.

(b.) The supporters of the second or chemical theory maintain that molecules of each substance come together in the solution to form a complex 'liquid-molecule,' while 'liquid-molecules' of the same kind unite on crystallisation and form the mixed crystals. Berthollet held this view, which is perhaps more generally accepted than the other; at the present time its chief exponent is Fock, who believes that the formation of mixed crystals and double salts are phenomena of the same order.

Use of mixed crystals as a test of isomorphism.—As we have seen, much weight has been attached to this property by Mitscherlich, Kopp, and others, but at the present time so many instances are known of the formation of mixed crystals by substances which cannot be considered isomorphous that the test

has lost much of its value (v. Lehmann, *l.c.*). Retgers (*l.c.*) has proposed that only those substances should be considered isomorphous, the physical properties of whose mixed crystals vary directly with the chemical composition.

ISOGONISM.—Speaking generally we find that if two substances are to be considered isomorphous they must satisfy the two following conditions: (i.) they must agree very closely in form and possess similar physical properties; (ii.) under suitable conditions they must be capable of forming layer- and mixed crystals. In Mitscherlich's definition we find, however, a third condition, viz. analogy of chemical constitution; and the question arises, How far may two substances which satisfy the two conditions above differ in chemical constitution and still be considered isomorphous? This question has received various answers; thus Scheibler (*J. pr.* 83, 273) has announced the isomorphism of most meta-tungstates, although they do not all contain the same number of molecules of water of crystallisation; Marignac (*C. R.* 55, 888) considers the two following series of substances to be isomorphous:—

And he also makes rhombohedral silicotungstic acid, and the acid silicotungstates of Ba and Ca isomorphous. Some other similar examples are given by Baker (*C. J.* 1879, 760). Klein (*C. R.* 95, 781) believes that the following substances are isomorphous:—

Klein, following Marignac, amends Mitscherlich's definition thus: 'Isomorphous substances have either an analogous chemical constitution or a very slightly different percentage composition; in the latter case they contain a group of common elements or elements of identical chemical function, this group making up by far the largest portion of the compound.' It seems, however, hardly advisable to widen Mitscherlich's definition; indeed, it is perhaps better if possible to narrow it by defining more closely what is meant by the phrases analogous chemical composition and analogous crystalline form.

Substances, such as the double fluorides described by Marignac, are not so much isomorphous as closely related morphotopically, while from them we may pass through substances exhibiting less and less of chemical analogy to those which agree in form alone, and which may therefore be considered as examples of isogonism (v. Retgers, *l.c.*). As an instance of this we may quote the remarkable analogy noticed by Hjortdahl (*C. R.* 88, 384) between the crystals of tin dimethyl and diethyl chlorides and lead chloride, which all crystallise in the rhombic system, and possess the following axial ratios:—

Tin dimethyl chloride	0.8341:1.0:0.9407
Tin diethyl chloride	0.8388:1.0:0.9452
Lead chloride	0.8408:1.0:0.9990.

At present it seems that substances which exhibit relations in form and composition may most

conveniently be divided into the following, more or less arbitrary groups, between whose limits no absolute line can be drawn:—

(1) Substances very closely related morphotropically, or isomorphous substances.—Bodies belonging to this class possess great chemical analogy, crystallise in the same system with nearly the same forms and angles, exhibit a general agreement in the physical properties of their crystals, and often possess the same specific volume; they are, moreover, under suitable conditions capable of forming mixed and layer-crystals. Such substances are the sulphates of the group $M''SO_4 \cdot 7H_2O$ ($M'' = Fe', Zn, Mg, Co, Ni$) and the alums.

(2) Substances closely related morphotropically.—To this class belong Marignac's double fluorides, and the substances derived from hydrocarbons by substitution; from them we pass on the one hand to isomerides such as the three dinitro-benzenes, which with a minimum difference of chemical constitution possess but little form-analogy, and on the other hand to bodies differing but little in form, but showing less and less chemical analogy, till we reach members of the next class.

(3) Isogonous substances, differing greatly in chemical composition but nearly similar in form.—To this class belong $CaCO_3$ and $KaNO_3$, and the substances described by Hjortdahl above, while all substances crystallising in the cubic system are strictly isogonous (*n. Sohncke, Entwicklung einer Theorie der Krystalstruktur*, Leipzig, 1879). A. H.

ISOPRENE v. PENTENES.

ISOPYRINE. An alkaloid obtained by boiling the mashed roots of *Isohyrum thalictroides* with water, filtering, evaporating to a syrup, ppg. with ammonia, and extracting with ether (Hartsen, *C. C.* 1872, 523). White powder with bitter taste, forming an amorphous hydrochloride.

Pseudo-isopyrine. After the roots have been boiled with water they still contain this alkaloid, which may be extracted with alcohol. After removing the alcohol by evaporation ammonia is added to the aqueous residue, and the ensuing pp. treated with ether, whence pseudo-isopyrine separates in needles. Its ppd. from its solution as hydrochloride by adding very dilute HCl and ammonium chloride (difference from isopyrine).

ISURETIN v. FORMAMIDOXIM.

ITABROMOPYROTARTARIC ACID v. BROMOPYROTARTARIC ACID.

ITACHLOROPYROTARTARIC ACID v. CHLORO-PYROTARTARIC ACIDS.

ITACONIC ACID $C_4H_4O_4$, i.e. $C_2H_3(CO_2H)_2$, or $CH_3 \cdot C(CO_2H) \cdot CH_2 \cdot CO_2H$ (?). Mol. w. 130. [161°]. S.G. 1.6 (Schröder, *B.* 13, 1072). S. 5 at 10°; 8 at 20°. S. (88 p.c. alcohol) 25 at 15° (Baup). R_{20} 44.25 (in a 4.18 p.c. aqueous solution) (Kanonnikoff, *J. pr.* [2] 81, 348). H.C. 476,580 (Lougouine, *C. R.* 106, 1291). Heat of solution 5,928 (Gal. a. Werner, *El.* [2] 47, 160). Heat of neutralisation 25,725 (G. a. W.). Shown by Raoult's method to be isomeric and not polymeric with citraconic and mesaconic acids (Paternò, *B.* 21, 2156).

Formation.—1. By the action of heat on citric acid, acetic acid being first formed (Baup, *A.* 19, 29; Crasso, *A.* 54, 68).—2. By

heating itamallic acid $C_4H_4O_4$ (Swarts, *Z.* 1867, 649).—3. By heating citric acid with water at 160° (Markownikoff a. Purgold, *Z.* 1867, 264).—4. By heating acetic acid with water at 180° (Pebal, *A.* 98, 94).—5. By heating citraconic anhydride with water under pressure (Fittig, *A.* 188, 72).

Preparation.—1. Coarsely-powdered citric acid (125 g.) is distilled from shallow retorts completely filled with it as quickly as the frothing will allow; the oily distillate is separated from the water as completely as possible and left to crystallise (Meilly, *A.* 171, 153; cf. Wilm, *A.* 141, 28). A temperature of 160°–175° is favorable to the formation of itaconic acid; at a very high temperature it is mostly converted into citraconic anhydride.—2. Citraconic anhydride (2 vols.) is heated with water (5 vols.) at 150° for 7 hours, and the product poured into flat dishes and left to crystallise (Fittig, *A.* 188, 72).

Properties.—Trimetric octahedra (from water). Strongly acid. Sol. ether. When heated above its melting-point it is resolved into citraconic anhydride and water. Ammonium itaconate gives a brown pp. with $FeCl_3$, soluble in excess of $FeCl_3$, but reppd. on boiling, and redissolved on cooling.

Reactions.—1. Combines with bromine, forming ita-di-bromo-pyrotartaric acid (Kekulé, *A. Suppl.* 1, 338; 2, 111; Cahours, *A. Ch.* [3] 67, 129).—2. Chlorine forms ita-di-chloro-pyrotartaric acid.—3. Heated with aqueous HBr , HCl , and HI , combination takes place with production of ita-bromo-, ita-chloro-, and ita-iodo-pyrotartaric acids. Excess of HI produces pyrotartaric acid (*Bl.* [2] 4, 374).—4. Sodium-amalgam reduces it to pyrotartaric acid (Kekulé).—5. $HOCl$ gives chloro-itamallic acid $C_4H_4ClO_4$.—6. Anhydrous HCy at 145° apparently forms an addition-product, which, when distilled, gives citraconic acid (Barbaglia, *B.* 7, 465).—7. Heated with aqueous K_2SO_4 it forms a gummy salt, possibly sulphopyrotartaric acid $C_4H_4SO_4$ (Wieland, *A.* 157, 34).—8. The electrolysis of the potassium salt yields a mixture of gases, apparently containing propylene and acetylene, but not allylene $CH_2:C:CH_2$ (Béhal, *A. Ch.* [6] 16, 366; cf. Aarland, *J. pr.* [2] 6, 256).—9. Cold HNO_3 gives off no CO_2 (Franchimont, *R. T. C.* 3, 422).

Constitution.—The molecular weight is shown by Raoult's method to be the same as that of citraconic and of mesaconic acids. According to Aarland potassium itaconate gives a different allylene on electrolysis from that derived from the potassium salts of citraconic and mesaconic acids; this would lead to the formula $CH_2:C(CO_2H) \cdot CH_2 \cdot CO_2H$. Béhal, however, was unable to confirm Aarland's experiments. According to Knops (*A.* 248, 228) the molecular refraction of the itaconic ethers indicates one $C:C$ group. Itaconic acid resembles mesaconic acid, but differs from citraconic acid in requiring heat to enable it to combine with HBr and with bromine. Itaconic acid reacts with aniline, but not with dimethylaniline.

Salts.— KHA'' aq: lustrous laminae; v. sol. water.— K_2A'' does not crystallise.— $(NH_4)HA''$: tables. S. 80 at 12°.— $(NH_4)_2A''$ aq: needles.— BaH_2A'' aq.— BaA'' aq (Petri, *AB.* 14, 1684).— CaH_2A'' 2aq. S. 7.7 at 12°.— CaA'' aq: needles. S. 2.2 at 18°.— $StrA''$ aq.— PbA'' aq.— FbA'' PbO

(Otto, *A.* 127, 181).— $\text{Ag}_2\text{A}''$: almost insol. boiling water.

Methyl ether $\text{Me}_2\text{A}''$. (212°). S.G. 1.1399 (Anschütz, *B.* 14, 3784); γ 1.1241 (Knops). $R_D = 80.44$. Oil. Polymerises, changing to a solid in which $R_D = 57.70$.

Ethyl ether $\text{Et}_2\text{A}''$. (229°). S.G. 1.051 (Anschütz); γ 1.0415 (Knops, *A.* 248, 210). $R_D = 75.52$. Polymerised: $R_D = 70.59$. From silver itaconate and EtI (Swarts, *Bull. Acad. royale Belgique* [2] 36, No. 7). Formed also by passing HCl into a solution of itaconic acid in alcohol. Colourless oil. Changes in a few days into a viscid liquid, and ultimately into a brittle, glassy mass, which is completely decomposed on distillation.

Chloride $\text{C}_4\text{H}_4(\text{COCl})_2$. (87°) at 17 mm. From the anhydride and PCl_5 . Colourless pungent liquid. Converted by water into itaconic acid (Petri).

Anhydride $\text{C}_4\text{H}_2(\text{C}_2\text{O}_3)_2$. [68°]. (148°) at 30 mm. Occurs among the products of the distillation of citric acid. Prepared by the action of AcCl on itaconic acid (Anschütz, *B.* 13, 1539) or on silver itaconate suspended in ether (Markownikoff, *B.* 13, 1844). Trimetric prisms; *abc*:*a* = 617:1:455. Sol. chloroform. Slowly dissolves in water with formation of itaconic acid. When distilled under atmospheric pressure it changes into the isomeric citraconic anhydride.

Amide $\text{C}_4\text{H}_5(\text{CONH}_2)_2$. [192°]. From $\text{Me}_2\text{A}''$ and aqueous NH_3 (O. Strecker, *B.* 15, 1639). Small colourless crystals (from water). V. e. sol. hot water, m. sol. alcohol, insol. ether.

Mono-anilide $\text{C}_4\text{H}_4(\text{CO}_2\text{H})(\text{CONHPh})$ or $\text{CO}_2\text{H} \cdot \text{CH} < \begin{smallmatrix} \text{CH}_2 \cdot \text{NPh} \\ \text{CH}_2 \cdot \text{CO} \end{smallmatrix} > (?)$. Itaconanilic acid.

[189°]. Formed by heating itaconic acid (5 g.) with water (50 g.) and aniline (3 g.) to boiling for half an hour, and depositing on cooling as crystals (Michael a. Palmer, *Am.* 9, 200; Gottlieb, *A.* 77, 266). Formed also by allowing a solution of acid aniline itaconate to stand for several days in the cold. Needles (from water). Insol. dilute HCl , aq. sol. dilute alkalis, and reprecipitated unchanged by acids.— BaA'_2 (at 170°).— CuA'_2 (at 160°).— AgA' .

Mono-anilide $\text{C}_4\text{H}_4(\text{CO}_2\text{H})(\text{CONHPh})$ (?). [151.5°]. From itaconic anhydride and aniline (Anschütz, *B.* 20, 3215; 21, 958). Not identical with the preceding.

Anilide $\text{C}_4\text{H}_4(\text{CONHPh})_2$. [185°]. Formed by heating aniline itaconate, or a mixture of itaconic acid, with excess of aniline at 180° (Gottlieb, *A.* 77, 282; O. Strecker, *B.* 15, 1639). Large thin plates; sol. alcohol and ether, sl. sol. water. A mixture of HNO_3 and H_2SO_4 converts it into an amorphous penta-nitro-derivative (Gottlieb, *A.* 85, 40).

Chloro-itaconic acid $\text{C}_4\text{H}_3\text{ClO}_4$. Formed by heating aconic acid $\text{C}_4\text{H}_3\text{O}_4$ with HCl (Swarts, *J.* 1873, 584). Crystalline crusts, sl. sol. cold water. Reconverted by boiling water into aconic acid.

Bromo-itaconic acid $\text{C}_4\text{H}_3\text{BrO}_4$. [164°]. Formed by the dry distillation of ita-di-bromopyrotartaric acid $\text{C}_4\text{H}_2\text{Br}_2\text{O}_6$ (Swarts, *Bull. Acad. roy. Belgique* [2] 88, No. 1). Also by heating aconic acid with HBr . Its anhydride is similarly formed from ita-di-bromo-pyrotartaric anhydride (Petri). Crystals resembling itaconic acid (from water); v. sl. sol. cold water; resolved by boiling

water or by alkaline carbonates into HBr and aconic acid. Reduced by tin or zinc to itaconic acid.

ITAMALIC ACID $\text{C}_8\text{H}_8\text{O}_6$. Oxy-pyrotartaric acid.

ITAPYRUVIC ACID $\text{C}_4\text{H}_4\text{O}_5$. Obtained, together with water and CO_2 , by distilling ita-tartaric acid at 125°–170° (Wilm, *A.* 141, 87). Viscid mass, v. sol. water and alcohol, volatile with steam.— BaA'_2 , aq. (at 100°): glassy amorphous mass.— PhA'_2 : hygroscopic amorphous mass, sl. sol. water. The silver salt is soluble, but very decomposable.

ITATARTARIC ACID $\text{C}_4\text{H}_4\text{O}_6$. Di-oxy-pyrotartaric acid. Formed by gradually adding a solution of HOCl to one of sodium itaconate (2 p.c. solution) at 0° in the dark, and boiling the resulting solution of chloro-oxy-pyrotartaric acid. The acid is ppd. as lead salt, which is subsequently decomposed by H_2S (Wilm, *A.* 141, 28; Morawsky, *J. pr.* [2] 10, 68; 11, 450). Formed also by warming ita-di-bromo-pyrotartaric acid with Ag_2O (Kekulé, *A. Suppl.* 1, 346). Amorphous vitreous deliquescent mass. V. e. sol. water and alcohol; not volatile with steam. Split up by dry distillation into CO_2 and itapyruvic acid. The alkaline salts prevent the ppn. of ferric and cupric salts by alkalis.— CaA'' aq: crystalline mass, sl. sol. water.— BaA'' (at 100°): amorphous, v. sol. water, and ppd. from aqueous solution by alcohol.— PhA'' aq: monoclinic tablets, v. sl. sol. water.— AgA'' : bulky pp., sol. water, but decomposed on boiling its solution.

IVAIN $\text{C}_{24}\text{H}_{40}\text{O}_{11}$. Occurs in *Iva*, the leaves and stem of *Achillea moschata* gathered before flowering (Von Planta, *A.* 155, 150). The volatile oil is first removed by distillation, and the residue is dried and extracted with alcohol, the filtrate is ppd. with lead acetate, freed from lead by H_2S , and evaporated. Dark yellow resinous mass, insol. water, v. sol. alcohol. The alcoholic solution has an extremely bitter taste.

IVY. *Hedera Helix*. When ivy leaves, collected in December, are bruised, exhausted with water, and then treated with alcohol, the alcoholic extract contains a glucoside $\text{C}_{24}\text{H}_{40}\text{O}_{11}$. This may be obtained by evaporating the alcohol, extracting the residue with benzene, and then with acetone, which deposits the glucoside on cooling (Vernet, *C. R.* 92, 360). It forms mammillary groups of silky colourless needles with slightly sweet taste and neutral reaction. It melts at 233°, and at 42° its alcoholic solution has a laevorotatory power of $[\alpha]_D = -47.6^\circ$. It is insol. water, chloroform, and petroleum; sl. sol. acetone, benzene, and ether in the cold, but readily soluble in these liquids when hot. V. sol. boiling alcohol. Sol. cold alkalis. The glucoside has no action on Fehling's solution, but on boiling with dilute H_2SO_4 a sugar is formed which crystallises by slow evaporation of its alcoholic solution in bulky transparent crystals with decided sweet taste, and reduces Fehling's solution, but is not fermented by yeast. The rotatory power of a cold solution of this sugar is $[\alpha]_D = +98.6^\circ$ immediately after its preparation, but some hours afterwards it has been found to fall to $[\alpha]_D = 70.2$. Besides the sugar, there is formed in the hydrolysis of the glucoside a neutral body $\text{C}_{24}\text{H}_{44}\text{O}_8$ [278°–280°], which crys-

tallises in slender prismatic needles, without taste, m. sol. alcohol, insol. alkalis, and dextro-rotatory $[\alpha]_D = 42.5^\circ$.

IXOLITE. A fossil resin found in a bed of bituminous coal at Oberhart. Fluid drops, hard-

ening to a hyacinth-red solid, which forms a yellowish powder. S.G. 1.008. Softens at 78° . Yields pyrocatechin on fusion with potash (Haidinger, P. 56, 345; Weidel, *Sitz. W.* [3] 74, 387).

J

JABONINE $C_8H_7N_2$, i.e.

$$CH \begin{array}{c} \text{CH:CH} \\ \text{N-CH} \end{array} > C_6H_5.NMe_2.$$
 Di-methyl-amido-ethyl-pyridine. ($235^\circ-240^\circ$). Formed by distilling pilocarpine or pilocarpidine with baryta (Hardy a. Calmels, *Bl.* [2] 48, 231). The crude product is evaporated several times with HClAq and the base set free with KOH. Colourless oil with foetid odour. Its hydro-chloride forms confusedly crystalline masses. The double salts $B'HauCl_4$, $B'AuCl_4$, B'_2PtCl_6 , and $B'_2H_2PtCl_6$ are all amorphous.

JABORANDI. The native name for several drugs of a sudorific and salivating character, consisting of the leaves and twigs of various species of *Pilocarpus* and other trees growing in Brazil, Pernambuco, and Paraguay (Holmes, *Ph.* [3] 5, 581, 641; Schelenz, *Ar. Ph.* [3] 7, 414; Baillon, *Ar. Ph.* [3] 7, 327). Jaborandi leaves contain pilocarpine (Byasson, *Ph.* [3] 5, 826; Hardy, *Bl.* [2] 24, 497), which readily changes to jaborine (H. Meyer a. Harnack, A. 204, 67). The latter acts like atropine, and is an antidote to pilocarpine. Pilocarpine $C_{11}H_{15}N_3O_2$ gives with MeI a methylo-iodide. Pilocarpidine $C_{10}H_{14}N_3O_2$ is also present in jaborandi (Harnack, A. 238, 231). It is crystalline but extremely deliquescent. It is alkaline, and turns yellow in light. V. sol. alcohol, m. sol. water, sl. sol. ether. Its sulphate and hydrochloride are deliquescent; its nitrate forms crystals resembling KNO_3 . Its platinum salt $B'_2H_2PtCl_6$ is crystalline. It readily changes when exposed to light into a base jaboridine $C_8H_7N_2O_2$, which has an amorphous platinum salt. The jaborandine of Chastaing (*C. R.* 94, 968) obtained from pilocarpine and HNO_3 is probably jaboridine (Harnack, A. 238, 238). The jaborandine of Parodi (*Revista farmaceutica*, 1875, 8) from *Piper reticulatum* $C_{10}H_{12}N_2O_2$ may be the same.

JABORIC ACID $C_{10}H_{12}N_2O_2$, i.e.

$$C_6H_5.N.CMe(OH).CO.O.NMe_2.CMe(C_6H_5N).CO_2H.$$
 Formed, together with NMe_2 , jaborine and pilocarpidine, by rapidly heating pilocarpine to 175° , and keeping it at that temperature for half an hour. If the product be extracted with baryta-water and the extract shaken with ether, the ether will contain jaborine, while pilocarpidine and jaboric acid remain in the aqueous solution. In this solution, after removing barium by CO_2 , $AgNO_3$ forms a curdy pp. of $C_{10}H_{12}N_2O_2.AgNO_3$, whence H_2S removes the silver (Hardy a. Calmels, *C. R.* 102, 1261; *Bl.* [2] 48, 225). Resinous mass, v. sol. water. Not removed from its aqueous solution by ether. With alkalis it forms gummy salts, sol. water and alcohol, and not decomposed by CO_2 . Hot conc. KOHAq or boiling HClAq converts it into pilocarpidine and oxy-pyridyl propionic acid $C_6H_5.N.CH_2.CH(OH).CO_2H$.

Salts.— AgA' : brown powder; ppd. by adding alcohol to a solution of the acid to which a limited quantity of $AgNO_3$ has been added.— $AgA'.AgNO_3$: curdy pp.— A'_2PtCl_6 : viscous pp.— $A'_2(PtCl_6)_2$: yellow powder.— $A'_2H_2PtCl_6$: sticky pp.— $A'(AuCl_4)_2$.

JABORIDINE $C_{10}H_{12}N_2O_2$. Formed by frequently evaporating pilocarpidine with acid (Harnack, A. 238, 234). Syrup; sol. water; m. sol. ether. Acts physiologically like jaborine though weaker. Its hydrochloride is syrupy, and v. sol. water.— $B'_2H_2PtCl_6$ (dried at 100°). [$110^\circ-120^\circ$]. Amorphous.

JABORINE $C_8H_7N_2O_2$, i.e.

$$NMe_2.CMe(C_6H_5N).CO.O.NMe_2.CMe(C_6H_5N).CO_2H.$$
 Occurs in jaborandi, and in false jaborandi (the leaves of *Piper reticulatum*). Prepared as described under Jaboric acid. Brittle resin. Insol. water, v. sol. ether, sol. alcohol. Dissolves in a solution of jaboric acid. Dissolves in HClAq, and is reppd. by KOH as a curdy pp. which readily agglomerates under warm water. Boiling conc. KOHAq converts it into pilocarpidine. Boiling HClAq does the same. Poisonous, acting like atropine.

Salts.—The hydrochloride is amorphous, and v. e. sol. water and alcohol.— B'_2PtCl_6 : dirty-white gelatinous pp.— B'_2PtCl_6 : yellowish-white pp.— $B'_2H_2PtCl_6$.— $B'(AuCl_4)_2$ (Hardy a. Calmels, *C. R.* 102, 1261).

JALAP. The roots and tubers of certain convolvulaceous plants which yield purgative resins. Official jalap consists of the tubers of *Convolvulus Schiedanus*, which contains Convolvulin, a strongly purgative resinous glucoside. Jalap-wood or jalap stalk (*Stipites Jalapae*), the root of *C. orizabensis*, contains a different glucoside, JALAPIN (Kayser, A. 51, 100; cf. Mayer, A. 95, 161).

JALAFIN $C_{22}H_{34}O_{10}$ or $C_{24}H_{36}O_{10}$ [160]. Occurs in the root-stalk of *Convolvulus* (or *Iporosa*) *orizabensis*, and forms the principal portion (soluble in ether) of the jalap resin prepared therefrom (Johnston, P. T. 1840, 842; P. M. [3] 17, 188; Kayser, A. 51, 101; Mayer, A. 83, 122; 95, 129; Hæule, *Rep.* 48, 365; Planche, J. Ph. 13, 165; 24, 169; Weppen, *N. Br. Arch.* 87, 153; Chevallier, J. Ph. 9, 506). Occurs also in the resin in scammony root from *Convolvulus Scammonia* (Johnston, P. T. 1840, 840; Keller, A. 104, 387, 109, 909; Spigatis, A. 116, 289; Planche, J. Ph. 13, 165; 18, 188; Marquart, *N. Br. Arch.* 7, 248; 10, 139).

Preparation.—1. Jalap resin is dissolved in a large quantity of alcohol, water is added until the liquid becomes slightly turbid, and the whole boiled with animal charcoal, filtered, ppd. by lead acetate and a little ammonia, filtered, freed

from lead by H_2S , the alcohol distilled off, and the residue kneaded in boiling water, and the jalapin finally extracted with ether (Mayer).—2. Finely powdered jalap resin is mixed with sand and extracted with ether, which deposits the jalapin on evaporation (Stevenson, *Ph.* [3] 10, 644).

Properties.—Colourless amorphous resin. Softens at 123° , and melts at 150° . Tasteless. V. s. sol. water; v. e. sol. alcohol, ether, and chloroform; sol. benzene, oil of turpentine, petroleum, and HOAc . Conc. H_2SO_4 dissolves it slowly in the cold, acquiring in a few minutes a maroon colour, but finally becoming black. With K_2CrO_7 , KMnO_4 , KClO_4 , or KNO_3 there is a brown colour and a smell of rancid butter; while MnO_2 gives a dark-green colour (Stevenson).

Reactions.—1. Boiling dilute HCl splits it up into sugar and jalapinol.—2. Boiling aqueous alkalis convert it into jalapic acid.—3. Nitric acid forms ipomic and oxalic acids.

Jalapic acid $\text{C}_{11}\text{H}_{18}\text{O}_{11}$ or $\text{C}_{10}\text{H}_{16}\text{O}_{10}$. [120°]. Formed by dissolving jalapin in aqueous alkalis (W. Mayer, *A.* 92, 125; 95, 129; Spirigatis, *A.* 116, 289). Prepared by boiling jalapin with baryta-water until the solution is no longer ppd. by acids; the baryta is then removed by H_2SO_4 , the excess of sulphate by lead hydrate, and the excess of lead by H_2S . Jalapic acid is then deposited on evaporating. Translucent, amorphous, yellowish, brittle mass. Softens below 100° , and melts about 120° . Has no smell, but an irritating taste and strong acid reaction. V. e. sol. water, v. sol. alcohol, m. sol. ether. In neutral solutions it is ppd. by lead subacetate, but not by any other metallic salt.

Reactions.—1. Fuming HCl splits it up into jalapinol and glucose. According to Spirigatis the products of hydrolysis of jalapic acid (and jalapin) derived from scammony are jalapinic acid and glucose.—2. Boiling dilute HCl forms (a) jalapic acid, so-called (Mayer).—3. HNO_3 gives ipomic, oxalic, and isobutyric acids.—4. KMnO_4 gives isobutyric, oxyisobutyric, and oxalic acids (Poleck a. Samelson, *O.C.* 1884, 818).

Salts.—Jalapic acid displaces CO_2 from aqueous Na_2CO_3 .— $\text{Ba}(\text{C}_{10}\text{H}_{16}\text{O}_{10})_2$: obtained on evaporating a solution of jalapic acid mixed with a slight excess of baryta-water after removing excess of baryta by CO_2 . Amorphous.— $\text{Ba}_2(\text{C}_{10}\text{H}_{16}\text{O}_{10})_3$: obtained by using baryta (2 pts.), water (4 pts.), and jalapic acid; passing CO_2 through the boiling solution, filtering and evaporating. Amorphous mass [100°].

(a) **Jalapic acid**, so-called. $\text{C}_{10}\text{H}_{16}\text{O}_{10}$. Formed, in small quantity, in the hydrolysis of jalapic acid by HClAq or dilute H_2SO_4 (Mayer). On cooling it separates with the jalapinol as a soft brown amorphous mass, which is then boiled with baryta-water, and the resulting solution deposits barium jalapinate on cooling. When the mother-liquor is concentrated silky needles of the Ba salt of (a) jalapic acid are obtained. The salt is decomposed by acetic acid. White flexible needles, melting below water at 80° . Feebly acid in reaction. Sl. sol. cold, m. sol. hot, water; v. e. sol. alcohol and ether. Boiling dilute acids split it up into jalapinol and glucose. HNO_3 gives ipomic acid and oxalic acid. Potash-fusion forms jalapinic acid and oxalic acid.—

$\text{Ba}(\text{C}_{10}\text{H}_{16}\text{O}_{10})_2$: White needles; sol. water and alcohol.

JALAPINOL $\text{C}_{10}\text{H}_{18}\text{O}_8$. [62°]. Formed, together with sugar, by the hydrolysis of jalapin and of jalapic acid (W. Mayer, *A.* 95, 145). $\text{C}_{10}\text{H}_{18}\text{O}_8 + 11\text{H}_2\text{O} = \text{C}_{10}\text{H}_{18}\text{O}_8 + 6\text{C}_6\text{H}_{12}\text{O}_6$. Prepared by allowing a solution of jalapic acid (2 vols.) mixed with fuming HClAq (1 vol.) to stand for a few days, washing the crystalline product with water, and recrystallising from alcohol, with use of animal charcoal, whence it separates in cauliflower-like groups of crystals. Insol. cold, v. sl. sol. boiling water, v. sol. alcohol and ether. Aqueous alkalis convert it into jalapinic acid. KMnO_4 forms isobutyric acid and (by further oxidation) oxyisobutyric acid (Poleck a. Samelson, *J.* 1884, 1447).

JALAPINOLIC ACID $\text{C}_{10}\text{H}_{16}\text{O}_9$. [64°]. Formed by treating jalapinol with aqueous KOH , ammonia, or baryta. Formed also by fusing jalapin or jalapic acid with KOH (Mayer, *A.* 95, 145; Spirigatis, *A.* 116, 306). According to Spirigatis it is also produced, together with sugar, by the action of mineral acids on jalapin and jalapic acid derived from scammony. Poleck and Samelson (*J.* 1884, 1447) by the action of alcoholic potash on jalapinol obtained, together with isobutyl alcohol, a jalapinic acid $\text{C}_{10}\text{H}_{16}\text{O}_9$. White tufts of minute thin four-sided prisms. Insol. water, v. sol. alcohol and ether. Lighter than water. Has an acid reaction. Nitric acid oxidises it to ipomic acid and oxalic acid.

Salts.— $(\text{NH}_4)\text{JA}'_2$: cauliflower heads of minute needles.— NaA'_2 (dried at 100°): slender needles.— BaA'_2 (dried at 120°): minute thin white needles; nearly insol. cold, sl. sol. boiling water; m. sol. boiling alcohol.— CuA'_2 (dried at 100°): greenish-blue pp. formed on mixing hot aqueous solutions of sodium jalapinate and CuSO_4 (Spirigatis).— $\text{Cu}_2\text{A}'_2(\text{OH})_2$ (dried at 100°). Ppd. by adding aqueous cupric acetate to a slightly alkaline solution of ammonium jalapinate. Amorphous dark-bluish-green mass.— PbA'_2 . Ppd. by adding lead acetate to an alcoholic solution of jalapinic acid mixed with a little ammonia. White amorphous mass.— AgA' . From aqueous AgNO_3 and alcoholic ammonium jalapinate. Flocculi.

Ethyl ether EtA'. [$32-5^\circ$]. From the acid (or from scammony) by saturation of the alcoholic solution with HCl , and ppg. with water. Flat tablets.

JAMBOSIN $\text{C}_{10}\text{H}_{18}\text{NO}_8$. [77°]. Occurs in the bark of jambosa root (the root of *Myrtus jambosa*?), from which it may be extracted with ether (Gerrard, *Ph.* [3] 14, 717). White tasteless crystals, sol. cold ether, alcohol, chloroform, and hot petroleum ether. Insol. cold, sol. boiling water. Conc. H_2SO_4 gives a bright-green colour changing to reddish-brown. Is not a glucoside. Does not form salts with bases. Has no medicinal properties.

JAPACONINE δ . ACONITE ALKALOIDS.

JAPACONITINE ν . ACONITE ALKALOIDS.

JAVANINE ν . CINCHONA BASES.

JECORIN $\text{C}_{10}\text{H}_{18}\text{N}_2\text{S}_2\text{Na}_2\text{O}_{11}$ (?). A substance obtained from liver (Drechsel, *J. pr.* [9] 33, 425). Occurs also in ox spleen, human brain, and horse's muscle (Baldi, *Ar. Physiol.* 1887, Suppl. 100). Amorphous substance. Hygroscopic, insoluble in dry ether, soluble in wet ether, v. sl.

in like manner by reducing nitroso-aceto-acetic ether. Ketine $C_4H_6O_2$ appears to be di-methyl-
 $\begin{array}{c} \text{OH} \cdot \text{N} \cdot \text{CMe} \quad \text{CH} \cdot \text{N} \cdot \text{CMe} \\ \text{pyrazine} \parallel \parallel \text{ or } \parallel \parallel \\ \text{CMe} \cdot \text{N} \cdot \text{CH} \quad \text{CMe} \cdot \text{N} \cdot \text{CH} \end{array}$, and will be

described as such (*cf.* Oeconomides, *B.* 19, 2524; Japp, *C. J.* 51, 98). Mayer (*B.* 21, 19) proposes to use the name *aldine* instead of pyrazine

for the group $\begin{array}{c} \text{CH} \cdot \text{N} \cdot \text{CH} \quad \text{CH} \cdot \text{N} \cdot \text{CH} \\ \parallel \quad \parallel \quad \text{or} \quad \parallel \quad \parallel \\ \text{CH} \cdot \text{N} \cdot \text{CH} \quad \text{CH} \cdot \text{N} \cdot \text{CH} \end{array}$. Other

alkyl-pyrazines are formed in like manner by the reduction of the nitroso-derivatives $\text{HO} \cdot \text{N} \cdot \text{CH} \cdot \text{CO} \cdot \text{C}_n\text{H}_{2n+1}$, of ketones of the form $\text{CH}_3 \cdot \text{CO} \cdot \text{C}_n\text{H}_{2n+1}$. As ketine di-carboxylic acid does not form an anhydride it has probably the

formula $\begin{array}{c} \text{CO}_2\text{H} \cdot \text{C} \cdot \text{N} \cdot \text{CMe} \\ \parallel \quad \parallel \\ \text{CMe} \cdot \text{N} \cdot \text{C} \cdot \text{CO}_2\text{H} \end{array}$ rather than

$\begin{array}{c} \text{CMe} \cdot \text{N} \cdot \text{C} \cdot \text{CO}_2\text{H} \\ \parallel \quad \parallel \\ \text{CMe} \cdot \text{N} \cdot \text{C} \cdot \text{CO}_2\text{H} \end{array}$, whence the symmetrical formula

for ketine given above (Oeconomides).

KETIPIC ACID. A name given to DI-METHYLDI-KETONE DI-CARBOXYLIC ACID, as it might perhaps be called di-keto-adipic acid.

KETO- This prefix is employed by some chemists to denote the displacement of H_2 in the group C_2H_5C by O . Thus quinone might be called di-keto-benzene, while aceto-acetic acid would be β -keto-butyric acid. The prefix 'keto-' does not indicate the introduction of a new organic group, whereas the corresponding prefix 'aldehydo-' indicates the introduction of the group CHO , and 'carboxy-' is used to denote the introduction of CO_2H . In order to avoid the confusion likely to arise from this circumstance the term 'keto-' is avoided in the headings of articles in this Dictionary: substances which might have such names given them are described as ketones, quinones, or oxy-compounds. The prefix **KETO-** has also been used as indicating substitution of hydrogen by the ketonic group $\text{CO} \cdot \text{CH}_3$, thus Erdmann (*B.* 21, 635) terms $\text{CH}_3 \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{OH}$ *keto-naphthol*. In keto-compounds the group $\text{CO} \cdot \text{CH}$ may often be regarded with equal propriety as $\text{C}(\text{OH}) \cdot \text{C}$, and such compounds are named in accordance with the latter formula. Thus phloroglucin may be described as tri-keto-benzene hexahydride or as tri-oxy-benzene.

DI-KETO-HEPTANE *v.* METHYL-BUTYL DI-KETONE.

DI-KETO-HEXANE *v.* METHYL-PROPYL DI-KETONE.

α , β -DIKETO-HEXYLENE *v.* METHYL-ALLYLDI-KETONE.

KETO-HEXA-HYDRO-BENZOIC ACID *CY-ANHYDRIN* *v.* Nitrils of OXY-ISOPHTHALIC ACID HEXAHYDRIDE.

DI-KETO-HYDRINDENE *v.* INDONAPHTHO-QUINONE.

DI-KETO-INDONAPHTHENE *v.* INDONAPHTHOQUINONE.

KETO-LACTONIC ACID $C_4H_6O_5$. [181°]. When α -acetyl- β -ethylsuccinic ether is heated it partly breaks up into alcohol and ethyl ketolactonate, which, on saponification, gives potassium ketolactonate (*S. Young, C. J.* 43, 175; *A.* 218, 45). It is also formed, together with $\text{CO}_2\text{H} \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Ac}$, by boiling the ether

($\text{CO}_2\text{Et} \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$) with dilute HCl , and may be extracted from the product by ether. The free acid crystallises from water, and is al. sol. cold water, m. sol. hot water.

Salts.— $\text{Ba} \cdot 2\text{H}_2\text{O} \cdot \text{AgA}'$.

Reaction.—1. Heated with *baryta* the following reaction occurs: $2\text{C}_4\text{H}_6\text{O}_4 + 8\text{BaO} + \text{H}_2\text{O} = 2\text{BaCO}_3 + \text{Ba}(\text{C}_4\text{H}_5\text{O}_3)_2$. The new acid, $\text{C}_4\text{H}_5\text{O}_3$, appears to be liquid; it forms a very soluble and unstable silver salt.—2. Cold *baryta* produces an unstable dibasic acid, $\text{C}_4\text{H}_5\text{O}_3$, by assimilation of H_2O .

Constitution.—Ketolactonic ether is formed from $\text{CO}_2\text{Et} \cdot \text{CH} \cdot \text{Ac} \cdot \text{CH} \cdot \text{CO}_2\text{Et}$ by splitting off HOEt . Inasmuch as $\text{CO}_2\text{Et} \cdot \text{CMe} \cdot \text{Ac} \cdot \text{CH} \cdot \text{CO}_2\text{Et}$ does not form in the same way the ether of a crystalline acid it is probable that the H which is here displaced by methyl goes to form alcohol in the formation of the ketolactonic ether. And since ketolactonic ether appears to be a lactone it should be

the acid being $\begin{array}{c} \text{CH}_3 \cdot \text{C} \cdot \text{O} \quad \parallel \\ \text{CO}_2\text{H} \cdot \text{C} \cdot \text{CH} \cdot \text{Et} \cdot \text{CO} \\ \parallel \\ \text{CH}_3 \cdot \text{C} \cdot \text{O} \quad \parallel \end{array}$

KETOLE. Another name for **NDOL** (Jackson, *B.* 14, 879).

KETONES. The ketones, in their simplest form, contain a carbonyl group CO attached to two monad hydrocarbon radicles. If the two radicles are identical, as in acetone (dimethyl-ketone) $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_3$, the compound is a *simple* ketone; if different, as in methyl-ethyl-ketone $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_3$, it is a *mixed* ketone.

Just as the fatty acids of the series $\text{C}_n\text{H}_{2n}\text{O}_2$ may be derived from the hypothetical carbonic acid $\text{CO}(\text{OH})_2$ by replacing one hydroxyl group by a monad hydrocarbon radicle, so the ketones may in turn be derived from the fatty acids by replacing the remaining hydroxyl group by a second radicle:

There is therefore a simple ketone derivable from each fatty acid by the introduction of a hydrocarbon radicle, identical with that which is attached to the carboxyl group of the acid, in place of its hydroxyl group.

If one of the radicles in a ketone is hydrogen the resulting compound is an aldehyde:

and owing to this similarity in constitution, the aldehydes and ketones have many reactions in common. In the case of formic acid the radicle attached to carboxyl is hydrogen, and the ketone therefore coincides with the aldehyde:

From this point of view the ketones may be regarded as homologues of formaldehyde.

Compounds containing two carbonyl groups are termed *diketones*; those containing three, *triketones*.

Fatty ketones.

Formation.—1. By the destructive distilla-

tion of the calcium salts, or, better still, of the barium salts, of acids of the series $C_nH_{2n}O_2$:

If a mixture of the salts of two acids is employed, a mixed ketone, containing the hydrocarbon radicals of both acids, is formed:

(Williamson, *C. J.* 1852, 238).

If one of the salts is a formate, an aldehyde is formed, a hydrogen atom from the formate attaching itself to the carbonyl-group:

(Piria, *Cimento*, 3, 126; *A.* 100, 104; Lippicht, *A.* 97, 368).

In the preparation of ketones by the destructive distillation of salts it is advantageous, if the molecular weight of the ketone is high, to conduct the distillation under reduced pressure (Krafft, *B.* 15, 1693).

2. By the destructive distillation of the calcium compounds of primary alcohols (Destrem, *A. Ch.* [5] 27, 7). In this reaction the alcohols are converted, with evolution of olefins and hydrogen, into salts of fatty acids:

and the calcium acetate is then decomposed by the heat, yielding acetone. A portion of the acetate, however, reacts with the calcium oxide, evolving methane.

3. By heating a mixture of the sodium compound of an alcohol and the sodium salt of a fatty acid in a current of carbon monoxide, mixtures of higher ketones are formed, along with sodium salts of higher organic acids (Geuther, *A.* 202, 238). The constitution of these ketones is not known with certainty, and the process in which they are formed is not understood.

4. By the action of acyl chlorides on zinc-alkyls (Freund, *A.* 118, 1; cf. Pawlow, *A.* 188, 104). The acyl chloride is added to the zinc-alkyl, at first gradually, afterwards more rapidly, cooling with ice during the operation. The mixture is then decomposed with excess of water:

If the mixture is allowed to stand too long before adding water, the additive compound formed in the first stage of the process reacts with a second mol. of alkyl chloride, exchanging its halogen for alkyl and generating a compound which, on treatment with water, yields a tertiary alcohol.

5. By the oxidation of secondary alcohols:

6. By the oxidation of secondary acids of the lactic series with potassium bichromate and dilute sulphuric acid. Thus hydroxy-isobutyric acid yields acetone:

7. Certain ketonic acids part with carbon dioxide, forming ketones. This decomposition takes place very readily in the case of the β -ketonic acids. Thus when ethylic acetate is warmed with a caustic alkali it is

hydrolysed, and the liberated acid splits off carbon dioxide, thus:

8. Alcohols containing a hydroxyl-group attached to a doubly-linked carbon-atom do not appear to be capable of existing in the free state, and change, at the moment of their formation, into either aldehydes or ketones, the former transformation occurring when the hydroxyl group is situated at the end of, the latter when it is within, the chain:

(Erlenmeyer, *B.* 13, 309; 14, 320).

9. When secondary or secondary-tertiary glycols are treated with dehydrating agents, such as phosphorus pentoxide or zinc chloride, they part with water, forming ketones. Probably an unsaturated alcohol is first produced, and this changes, at the moment of its formation, into a ketone (v. preceding paragraph):

Primary glycols, when thus treated, yield aldehydes. Tertiary glycols (pinacolones) are dehydrated even by boiling with dilute sulphuric acid, forming ketones, the reaction being accompanied in this case by the migration of an alkyl group:

10. When the homologues of acetylene are passed into a solution of mercuric chloride heated to 90°-95° they take up the elements of water, yielding ketones (Kutscherow, *B.* 17, 13):

Acetylene itself yields aldehyde.

11. Ketones, especially acetone, are formed in the destructive distillation of wood, sugar, citric acid, and various other organic compounds.

Properties and Reactions.—The lower members of the ketone series are liquids, with a peculiar ethereal odour, boiling without decomposition. The higher homologues, beginning with $C_{12}H_{22}O$, are crystalline solids.

The ketones are isomeric with the aldehydes containing the same number of atoms of carbon. They closely resemble the aldehydes in many of their reactions, but are distinguished from them by not reducing ammoniacal silver solutions. Like the aldehydes, many of the ketones combine with the hydrogen sulphites of the alkalis to form crystalline double compounds. The rule given by Grimm (*A.* 157, 262) that only those ketones combine with hydrogen sodium sulphite which contain the group $CH_3.CO$, holds very generally: an exception is propione (diethyl ketone) $CO(C_2H_5)_2$, which forms a double compound, although with difficulty. These compounds are used in separating and purifying the ketones: on treating the double compound with sodium carbonate the ketone is liberated. The ketones, like the aldehydes, unite with hydrocyanic acid to form nitriles or hydroxy-acids: $(CH_3)_2CO + HCN = (CH_3)_2C(OH).CN$ (Urech, *A.* 104, 258; Tiemann & Friedländer, *B.* 14, 1971) and these nitriles react with ammonia, yielding nitriles of amido-acids: $(CH_3)_2C(OH).CN + NH_3 = (CH_3)_2C(NH_2).CN + H_2O$ (T. & F.). — In

presence of caustic potash, acetone unites with chloroform to form acetone-chloroform $(CH_3)_2C(OH).OCl$, which when heated with water to 180° yields hydroxy-isobutyric acid and hydrochloric acid. (Willgerodt, *B.* 14, 2451; 16, 1585).—*Sodium amalgam*, acting on aqueous solutions of the ketones, reduces them to secondary alcohols; thus acetone is converted into isopropyl alcohol: $(CH_3)_2CO + H_2 = (CH_3)_2CH.OH$ (Friedel, *C. R.* 55, 53). At the same time, a second reaction occurs in which 2 mols. of the ketone are united during the process of reduction, forming a tertiary glycol, or pinacone: $2(CH_3)_2CO + H_2 = (CH_3)_2C(OH).C(OH)(CH_3)_2$.—The ketones are less susceptible of oxidation than the aldehydes, and, unlike the latter, can never yield by oxidation an acid containing the same number of carbon atoms. They are best oxidised by boiling them with a mixture of potassium bichromate and dilute sulphuric acid. Popoff (*A.* 161, 300) has formulated the following rules regarding the products formed in the oxidation of the ketones—rules to which, however, there are occasional exceptions: The ketone is broken up at a point between the carbonyl group and one of the alkyl groups, the combined carbonyl being oxidised to carboxyl, and the separated alkyl being oxidised, if primary, to a fatty acid with the same number of atoms of carbon as the alkyl itself, and if secondary, to a ketone, which may in turn be further oxidised. If a ketone contains two dissimilar alkyls, the carbonyl group will remain attached to that carbon atom which has most hydrogen combined with it, unless in the case of a tertiary alkyl or a radicle of the benzene series, when the carbonyl group will remain in combination with the non-hydrogenated carbon atoms. If the two dissimilar alkyls are both primary, or both secondary, or both tertiary, the carbonyl will remain attached to the alkyl of lower molecular weight. The following equations illustrate these rules:

In several cases, however, a subordinate reaction, in which the ketone is oxidised in a way the reverse of that predicted by the rule, occurs simultaneously.—*Chlorine* and *bromine* give substitution compounds.—*Phosphorus pentachloride* replaces the oxygen of ketones by two chlorine atoms.—*Ammonia* reacts less readily with ketones than with aldehydes. With acetone it forms diacetoneamine $C_6H_{11}NO$, and triacetoneamine $C_9H_{17}NO$.—With *hydroxylamine* in aqueous solution the ketones yield the ketoximes:

The ketoximes are generally solid crystalline compounds, volatile without decomposition. Concentrated hydrochloric acid decomposes them into hydroxylamine and ketone.—In like

manner *phenylhydrazine* reacts with the ketones, eliminating water and forming ketohydrazones:

The ketohydrazones of the fatty series are for the most part oily liquids, which may be distilled under reduced pressure. Acids decompose them into phenylhydrazine and ketones (E. Fischer, *B.* 16, 661).—*Nitrous acid* converts the ketones into isonitroso-ketones. The reaction occurs more readily, however, with ethereal salts of nitrous acid; thus when a mixture of amyl nitrite and acetone is warmed with hydrochloric acid isonitroso-acetone is formed:

Sodium ethoxide may be substituted for hydrochloric acid in the foregoing reaction, but in this case the sodium compound of the isonitroso-ketone is formed and must afterwards be decomposed by acetic acid (Claisen, *B.* 20, 252, and 656; Claisen a. Manasse, *B.* 20, 2194). The isonitroso-ketones are also readily obtained by the action of nitrous acid on aceto-acetic acid and its homologues:

(V. Meyer a. Züblin, *B.* 11, 695; Ceresole, *B.* 15, 1328).—Concentrated *nitric acid* converts the ketones into dinitro-paraffins: thus propione $CH_3.CH_2.CO.CH_2.CH_3$ yields dinitroethane $CH_3.CH(NO_2)_2$ (Chancel, *Bl.* 31, 504).—The ketones react with the *mercaptans*, eliminating water and yielding 'mercaptols' (thioketates); ethyl thiodimethylketate is formed when gaseous hydrochloric acid is passed into a mixture of acetone and mercaptan: $(CH_3)_2CO + 2C_2H_5.SH = (CH_3)_2C(S.C_2H_5)_2 + H_2O$ (Baumann, *B.* 18, 887). The mercaptols are liquids, insoluble in water, not volatile without decomposition, stable towards alkalis and dilute acids.—Under the influence of *dehydrating agents*, such as sulphuric acid, zinc chloride, hydrochloric acid, &c., the ketones readily undergo condensation, two or more molecules combining, with elimination of water, to form more complex compounds. Thus 2 mols. of acetone unite to form mesityl oxide $(CH_3)_2C:CH.CO.CH_3$, and 3 mols. to form either phorone $(CH_3)_2C:CH.CO.CH:CH(C_6H_5)_2$, or mesitylene (1, 3, 5-trimethylbenzene) $C_6H_3(CH_3)_3$, according as 2 or 3 mols. of water are eliminated in the process.

Benzene ketones. Ketones of this class may either contain two benzene radicles directly attached to carbonyl, as in benzophenone (diphenyl ketone) $C_6H_5.CO.C_6H_5$, or the carbonyl group may unite a benzene radicle and a fatty radicle, as in acetophenone (phenyl-methylketone) $C_6H_5.CO.CH_3$; or one or both of the benzene radicles may be attached to carbonyl by means of a fatty group, as in phenyl-benzylketone $C_6H_5.CO.CH_2.C_6H_5$, or di-benzylketone $C_6H_5.CH_2.CO.CH_2.C_6H_5$.

Preparation.—Many of the methods already described for the preparation of the fatty ketones are also applicable in the case of the benzene

ketones. Thus benzophenone may be obtained by the distillation of a benzoate:

Again, acetophenone may be obtained by the action of benzoyl chloride on zinc methyl; but if it is desired to introduce a benzene radicle in place of the halogen of the acyl chloride the mercury compound of that radicle must be employed: $\text{C}_6\text{H}_5\text{COCl} + \text{Hg}(\text{C}_6\text{H}_5)_2$

The benzene ketones are also formed, like the fatty ketones, by the oxidation of the corresponding secondary alcohols:

and of secondary glycolic acids containing benzene radicles:

further, by splitting off carbon dioxide from ketonic acids of the benzene series:

By shaking phenylacetylene with sulphuric acid of 75 p.c. it takes up the elements of water, yielding acetophenone:

The following modes of formation are peculiar to benzene ketones:—

1. By the action of an acyl chloride on a benzene hydrocarbon in presence of aluminium chloride: $\text{CH}_3\text{COCl} + \text{C}_6\text{H}_6 = \text{CH}_3\text{CO.C}_6\text{H}_5 + \text{HCl}$ (Friedel a. Crafts, *A. Ch.* [6] 1, 507). In this reaction the acid radicle always attaches itself to a benzene nucleus, and never to a fatty group. In like manner ketones containing two benzene radicles directly united to carbonyl may be prepared by acting on a benzene hydrocarbon with carbonyl chloride in presence of aluminium chloride: $\text{COCl}_2 + 2\text{C}_6\text{H}_6 = \text{CO}(\text{C}_6\text{H}_5)_2 + 2\text{HCl}$.

2. The last-mentioned class of ketones may also be obtained by heating a mixture of a benzene carboxylic acid and a benzene hydrocarbon with phosphorus pentoxide:

3. By the oxidation of hydrocarbons in which two benzene radicles are united by a methylene-group:

Ketone-alcohols are obtained by polymerising benzene aldehydes with potassium cyanide:

Ketone-phenols are formed when acyl chlorides of the benzene series act on phenols in presence of zinc:

The acid radicle enters the nucleus of the phenol in the para-position to the hydroxyl group.

Properties and Reactions.—The benzene ketones are liquids and solids, boiling without decomposition and having a pleasant aromatic odour.

In most of their reactions they closely resemble the fatty ketones. Popoff's rules (*supra*) apply to the oxidation of the benzene ketones: the carbonyl group always remains attached to a benzene nucleus to which it is directly united. Like the fatty ketones, the benzene ketones react with hydroxylamine and with phenyl-hydrazine eliminating water and yielding hydroximes and hydrazones. On reduction with sodium-amalgam they form secondary alcohols; but heating with hydriodic acid, or distillation with zinc-dust, reduces them to the corresponding hydrocarbons:

By fusion with caustic alkalis they yield a salt of a benzene acid together with a hydrocarbon:

$\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_5 + \text{KOH} = \text{C}_6\text{H}_5\text{CO}_2\text{K} + \text{C}_6\text{H}_6$. They are less subject than the fatty ketones to undergo condensation with elimination of water, and those which contain two benzene radicles directly attached to the carbonyl group do not exhibit this tendency at all.

Only those benzene ketones combine with hydrogen sodium sulphite in which the carbonyl is attached to two fatty groups, one of which is methyl: thus, benzyl-methyl-ketone $\text{C}_6\text{H}_5\text{CH}_2\text{CO.CH}_3$ and methyl-phenylethyl-ketone $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CO.CH}_3$ form double compounds; acetophenone $\text{C}_6\text{H}_5\text{CO.CH}_3$ does not.

Diketones. The diketones contain two carbonyl groups attached to hydrocarbon radicles. If the two carbonyl groups are directly united, the compound is an α -diketone; if they are united by a carbon atom, it is a β -diketone; if by a chain of two carbon atoms, a γ -ketone, and so on.

Some of the diketones, such as benzil $\text{C}_6\text{H}_5\text{CO.CO.C}_6\text{H}_5$, have been known for a considerable time; but the majority are of recent discovery. Their chief interest lies in the ease with which the two carbonyl groups may be made to condense with one or more molecules of some other substance to form closed-chain compounds. In this way glyoxalines, quinolines, pyrazoles, furfurans, pyrroles, thiophenes, and similar compounds have been prepared.

α -Diketones. These may be regarded as homologues of the dialdehyde *glyoxal*, CHO.CHO . They may be obtained by the action of chlorine, or, better, of nitric acid, on α -ketone-alcohols:

(Laurent, *A. Ch.* [2] 59, 402; Zinin, *A.* 84, 188). By hydrolysing the isonitrosoketones by boiling them with dilute sulphuric acid:

(Von Pechmann, *B.* 21, 1411).

The benzenoid α -diketones react with caustic potash to form secondary glycolic acids, the two

hydrocarbon radicals attaching themselves to the same carbon atom:

(Liebig, *A.* 25, 26; Zinin, *A.* 31, 329). In like manner glyoxal yields glycolic acid. The fatty α -diketones, however, condense to form quinones (*q. v.*).— α -Diketones react with 2 mols. of hydroxylamine to form dihydroximes. Benzil dihydroxime is remarkable as occurring in three isomeric modifications, all of the formula $\text{C}_6\text{H}_5\text{C}(\text{N.OH}).\text{C}(\text{N.OH}).\text{C}_6\text{H}_5$, an isomerism which is explained by Victor Meyer by means of tridimensional formulae (Auwers a. V. Meyer, *B.* 22, 705; cf. also Hantzsch a. Werner, *B.* 23, 11). These three hydroximes, when heated, part with water, yielding in each case the same closed-chain compound—an anhydride:

(Auwers a. V. Meyer, *B.* 21, 810).—With α -diamines the α -diketones yield quinoxalines ('azines):

(Hinsberg, *B.* 17, 322; cf. Witt, *B.* 19, 915). For an account of the behaviour of α -diketones with aldehydes and ammonia *v. v.* vol. i. p. 465.

β -Diketones. The lowest member of this series which is a true diketone and not a dialdehyde is acetyl-acetone $\text{CH}_3\text{CO.CH}_2\text{CO.CH}_3$. By the action of aluminium chloride on acetyl chloride a crystalline substance of the formula $\text{C}_2\text{H}_5\text{O}_2\text{Al}_2\text{Cl}_2$ is formed, which, on treatment with water, evolves carbon dioxide and yields acetyl-acetone (Combes, *C. R.* 103, 814). A general method for the preparation of β -diketones consists in acting on a mixture of a fatty or a benzene-fatty ketone and the ethyl salt of a carboxylic acid with sodium ethoxide. The latter substance produces condensation between the ethereal salt and the ketone with elimination of alcohol:

In reality it is the sodium compound of benzoyl-acetone $\text{C}_6\text{H}_5\text{CO.CHNa.CO.C}_6\text{H}_5$, which is formed, and it is necessary to decompose this compound with carbon dioxide in order to obtain the free diketone (Claisen, *B.* 20, 655). Di-acyl derivatives of acetic acid are decomposed on boiling with water, eliminating water and generating β -diketones:

(Baeyer a. W. H. Perkin, jun., *B.* 16, 2128; E. Fischer a. Kuzel, *B.* 16, 2239).

The methylene group in the β -diketones is attached to two electro-negative carbonyl groups,

For this reason one atom of hydrogen in this group, like the hydrogen in the methylene group of aceto-acetic ether or malonic ether, is replaceable by an alkali metal when presented to it in the form of an ethoxide. By treating the alkali compound thus obtained with the halogen compound of an alkyl or acid radical, the radical can be introduced in place of the alkali metal:

The β -diketones react with 1 mol. of phenylhydrazine eliminating 2 mols. of water, and forming pyrazoles:

(Knorr, *B.* 20, 1104).—Aniline reacts with β -diketones in two stages: thus when benzoyl-acetone is heated with aniline at 150° the two substances first unite, parting with 1 mol. of water: $\text{C}_6\text{H}_5\text{CO.CH}_2\text{CO.CH}_3 + \text{C}_6\text{H}_5\text{NH}_2 = \text{C}_6\text{H}_5\text{CO.CH}_2\text{C}(\text{N.C}_6\text{H}_5)\text{CH}_3 + \text{H}_2\text{O}$; and when the compound thus obtained is heated with concentrated sulphuric acid, it parts with a second mol. of water, forming a quinoline derivative:

(C. Beyer, *B.* 20, 1770). This is a general method for the preparation of quinolines containing alkyls in the α - γ positions.

γ -Diketones.—In these compounds the two carbonyl-groups are united by an ethylene radical. The lowest member of the series, acetoacetyl-acetone, was obtained by Faal (*B.* 18, 58) by heating pyrotritaric acid with water at 150° – 160° :

$\text{—CH}_2\text{CO.CH}_2\text{CH}_2\text{CO.CH}_3 + \text{CO}_2$. Acetophenone-acetone is obtained by heating acetophenone-aceto-acetic acid (prepared by acting with bromoacetophenone on sodiaceto-acetic ether, and hydrolysing the ether thus formed):

$\text{—CH}_3\text{CO.CH}_2\text{CH}_2\text{CO.C}_6\text{H}_5 + \text{CO}_2$ (Faal, *B.* 16, 2865).

By treatment with dehydrating agents, such as fuming hydrochloric acid or acetic anhy-

aldehyde, the γ -diketones are converted into furfurans. It is supposed that in this reaction the diketone first forms a 'labile' modification containing two hydroxyl groups, and that this then parts with water to form the furfuran:

(Paal, B. 17, 2756). An unsaturated ketone isomeric with phenylmethylfurfuran is formed at the same time.—Phosphorus pentasulphide converts γ -diketones into thiophenes, whilst with ammonia they yield pyrroles, the reaction in both cases being supposed to be preceded by the above-mentioned transformation of the diketone into its 'labile' modification:

and

(Paal, B. 18, 367).

An unsaturated γ -diketone, anhydrazoacetophenonebenzil ($\alpha\beta$ -dibenzoylstyrolene) is formed by the action of caustic potash on a mixture of benzil and acetophenone:

Quinones. If the two carbonyl groups of a diketone occur in a closed chain of six carbon atoms, the resulting compound belongs to the class of the quinones. This group of diketones will be treated of separately (v. QUINONES).

Triketones. A triketone is which the three carbonyl groups are directly united has been obtained in the following manner (von Pechmann, B. 22, 852): Dibenzoylbromomethane

$\text{C}_6\text{H}_5\text{CO}\cdot\text{CHBr}\cdot\text{CO}\cdot\text{C}_6\text{H}_5$ (prepared by the action of bromine on dibenzoylmethane, v. supra) is converted by treatment with potassium acetate into the acetate of dibenzoylcarbinol $\text{C}_6\text{H}_5\text{CO}\cdot\text{CH}(\text{OC}_2\text{H}_5\text{O})\cdot\text{CO}\cdot\text{C}_6\text{H}_5$, which, when brominated, yields $\text{C}_6\text{H}_5\text{CO}\cdot\text{CBr}(\text{OC}_2\text{H}_5\text{O})\cdot\text{CO}\cdot\text{C}_6\text{H}_5$. When this compound is heated above its melting-point (101.5°) it breaks up into acetyl bromide and diphenyltriketone:

Diphenyltriketone, like some other compounds in which a carbonyl-group is situated between two electro-negative groups, unites with 1 mol. of water to form a hydrate; this has probably the constitution $\text{C}_6\text{H}_5\text{CO}\cdot\text{C}(\text{OH})_2\cdot\text{CO}\cdot\text{C}_6\text{H}_5$.

The formation of another triketone, *tribenzoylmethane*, in which the three carbonyl-groups are attached to the same carbon atom, has already been referred to.

F. R. J.

DIKETO-PENTANE v. METHYL ETHYL DIKETONE.

$\alpha\beta$ -DIKETO-PROPYL-BENZENE v. PHENYL-METHYL-DIKETONE.

KINIC ACID. Synonym of QUINIC ACID.

KINO. The dried juice, obtained from incisions in the trunk of *Pterocarpus marsupium* (Malabar). The name has also been given to the dried juice from other trees, e.g. *Eucalyptus resinifera* (Australia), *Pterocarpus erinaceus*, and *Coccoloba uvifera* (America). Kino greatly resembles catechu, and is used in dyeing and in medicine. It occurs in small brittle opaque reddish-black fragments, partly soluble in water, almost entirely soluble in alcohol, insoluble in ether. It has no odour, but a very astringent taste. Used in medicine as an astringent. It gives off pyrocatechin when distilled (Eisfeld, A. 92, 101). Potash-fusion forms phloroglucin and protocatechuic acid (Hlasiwetz, A. 134, 122; Stenhouse, A. 177, 187). Kino contains kinoïn and kino-red and other bodies. Kinoïn has been described as a 'tannin' (Bergholz, cf. Etti, B. 17, 2241).

Kinoïn $\text{C}_{14}\text{H}_{10}\text{O}_6$. Occurs together with kino-red, &c., in gum kino, from which it is extracted by first boiling with dilute HCl, and then extracting the solution with ether; yield 1½ p. (Etti, B. 11, 1879). Colourless prisms. Sl. sol. cold, readily sol. hot, water. On heating to 120° it gives kino-red ($\text{C}_{14}\text{H}_{10}\text{O}_5$). On heating with HCl to 130° it is decomposed into methyl chloride, pyrocatechin, and gallic acid.

Kino-red $\text{C}_{14}\text{H}_{10}\text{O}_5$. [160° - 170°]. A red resin occurring in kino and left undissolved when it is boiled with dilute HCl. It is also formed by heating kinoïn. It is sl. sol. water, v. sol. alcohol. FeCl₃ gives a dirty green colouration. It dissolves in alkalis. It ppts. a solution of gelatin. On fusion it yields a red amorphous anhydride $\text{C}_{14}\text{H}_{10}\text{O}_4$, which also ppts. a solution of gelatin. The anhydride is also formed by heating kino-red with dilute HClAq. Kino-red yields phenol and pyrocatechin when distilled.

KOSIN $\text{C}_{14}\text{H}_{10}\text{O}_{10}$. [142°]. Obtained from cusso or koussou, the dried flowers of the Abyssinian koso tree (*Hagenia Abyssinica*), used by the inhabitants as a remedy against tape worm (Flückiger & Buri, Ar. Ph. [8] 5, 193; Ph. [8] 5, 562). The anthelmintic properties of koso seem to be due to kosin. Sulphur-yellow trimetric crystals. Nearly insol. water, v. sol.

alcohol, ether, benzene, CS_2 , chloroform, and HOAc . Dissolves in aqueous alkalis and Na_2CO_3 , and is reppd. by acids. FeCl_3 colours its alcoholic solution permanently red. Conc. H_2SO_4 does not decompose it at 15° , but on warming it forms isobutyric acid and a red amorphous body $\text{C}_8\text{H}_8\text{O}_2$ (?). Potash-fusion gives formic, butyric, and oxalic acids. Sodium-amalgam yields a volatile oil $\text{C}_8\text{H}_8\text{O}$ and an amorphous yellow substance $(\text{C}_8\text{H}_8\text{O}_2)_n$.

Acetyl derivative $\text{C}_{11}\text{H}_{12}\text{Ac}_2\text{O}_6$. From kosin and Ac_2O .

KOUMISS v. MILK.

KYANETHINE v. CYANETHINE.

KYANPHENINE v. CYAPHENINE.

KYANPROPINE v. CYANPROPINE.

KYNURENIC ACID v. OXY-QUINOLINE CARBOXYLIC ACID.

KYNURIC ACID v. CYNURIC ACID.

KYNURIN v. OXY-QUINOLINE.

L

LABURNINE. An alkaloid said to occur along with cytisine in laburnum seeds (Husemann a. Marmé, Z. [2] 1, 161; 5, 677). Light crystalline groups of monoclinic prisms; v. sol. water, sl. sol. alcohol, nearly insol. ether.

LAC. A substance surrounding the eggs of *Coccus lacca* on the twigs of various trees in Bengal and Sumatra. These twigs are called stick-lac. The lac is removed by melting and squeezing through canvas, when the hardened drops are known as seed-lac. After bleaching by chlorine or charcoal and making into sticks it is known as shell-lac or shellac. Lac is used for making sealing-wax, varnishes, and a red dye called lac dye. Lac contains 68 to 88 p.c. resin (about half of which is soluble in ether), a small quantity of wax and of a red dye, and a larger quantity of a substance insoluble in alcohol. The wax [60°] contains ceryl and myricyl alcohols and their stearic, palmitic, and oleic ethers (Benedikt a. Ulzer, M. 9, 579). Shellac may be freed from wax by dissolving in boiling dilute Na_2CO_3 , filtering, and ppg. with HCl . If the boiling be continued too long, liquid shellac is produced. Shellac freed from wax gives azelaic acid when oxidised by KMnO_4 (Benedikt a. Ehrlich, M. 9, 163).

Liquid shellac $\text{C}_{18}\text{H}_{16}\text{O}_2$. Formed by boiling shellac (1,000 g.) with NaOH (300 g.) and water (20,000 g.) for 2 hours. When cold, sulphuric acid is added and the liquid shaken with ether (B. a. E.). Thick liquid; insol. water, v. sol. alcohol and ether. Forms salts with Pb, Ag, Zn, Ba, and Ca— $\text{C}_{18}\text{H}_{16}\text{MgO}_2$; amorphous, v. sol. water; ppg. on heating, but redissolves on cooling.

Laccalic acid $\text{C}_{18}\text{H}_{16}\text{O}_2$ (?). Obtained from lac dye by treating with HClAq , filtering, boiling the residue with water, ppg. the solution with lead acetate, and decomposing the pp. with H_2S (R. E. Schmidt, B. 20, 1285). Brownish-red powder composed of minute tables (from alcohol-ether), m. sol. alcohol, sl. sol. water, nearly insol. ether, insol. benzene. Decomposes, without previous fusion, at about 180° . Alkalis form a crimson solution which has an absorption spectrum like that of carminic acid. Baryta gives a violet pp.: FeSO_4 , a black pp.: FeCl_3 , a black colouration only. It reduces ammoniacal AgNO_3 , but not Fehling's solution. Conc. HNO_3 yields picric and oxalic acids. Conc. HClAq at 180° forms a substance $\text{C}_{18}\text{H}_{16}\text{O}_2$. Laccalic acid dyes like carminic acid, but its solution in H_2SO_4 shows a different absorption spectrum.— $\text{K}_2\text{C}_{18}\text{H}_{16}\text{O}_2$ (dried

at 100°): flocculent pp. formed by adding alcoholic potash to an alcoholic solution of the salt. $\text{BaC}_{18}\text{H}_{16}\text{O}_2$: brownish-red pp. formed by adding NH_3 and BaCl_2 .

LACMOID.

Preparation.—1. A mixture of resorcinol (20 pts.), sodium nitrite (1 pt.), and water (1 pt.) is slowly heated to 110° , at which temperature a vigorous reaction sets in, the melt is then kept at 115° – 120° till it has become quite blue and the evolution of NH_3 has ceased (Traub a. Hook, B. 17, 2615).—2. By the action of H_2O_2 on ammoniacal resorcin solution (Wurster, B. 20, 2938).—3. By fusing resorcin (15 g.) with KNO_3 (18 g.) (Benedikt a. Julius, M. 5, 534).

Properties.—Glistening brown powder. It is easily soluble in methyl, ethyl, and amyl alcohols, acetone, acetic acid, and phenol, less easily in ether and water, insoluble in benzene and petroleum-spirit. It dissolves in strong HCl or H_2SO_4 with a blue colour. It decomposes below 200° .

Lacmoid differs from litmin, the colouring matter of litmus, in being soluble in strong alcohol. Litmin is insoluble in strong alcohol, though soluble in dilute (50 p.c.) spirit. The solution of litmin in 50 p.c. alcohol is bleached after a time, while that of lacmoid retains its colour for months. The absorption spectra of the two substances do not differ markedly (Hartley, R. Dublin Soc. 5, 169).

LACTAM. The anhydride of an amido-acid

$\text{R}''(\text{NH}_2)(\text{CO}_2\text{H})$ containing the group $\text{R}'' \begin{matrix} \text{CO} \\ \diagup \\ \text{NH} \end{matrix}$ (Baeyer, B. 15, 2102).

LACTAMIC ACID is α -AMIDO-PROPIONIC ACID.

Di-lactamic acid is α -IMIDO-DI-PROPIONIC ACID.

LACTAMIDE v. AMIDE OF LACTIC ACID.

LACTARIC ACID $\text{C}_4\text{H}_6\text{O}_6$. Prepared by pressing the juice out of the mushroom (*Lactarius piperatus*) and extracting the residue with ether or boiling alcohol (Chuit, Bl. [3] 2, 153). White leaflets (from alcohol); v. sol. hot alcohol, ether, CHCl_3 , CS_2 , and benzene, v. sl. sol. cold alcohol and petroleum spirit, insol. water.

Salts.— NaA' : greasy scales, decomposing at 250° .— KA' : silvery scales, decomposing at 245° without melting.— KHA' : silky scales. [115°].— $\text{NH}_4\text{A}'$: [92°]; white leaflets, decomposed by boiling water.— CaA' : scales. When distilled it forms the ketone $(\text{C}_4\text{H}_4\text{O})_2\text{CO}$ [92°].— BaA' : white amorphous pp. Insol. water, alcohol, and ether.— PbHA' : [114°]. Thin transparent leaflets.

Methyl ether MeA'. [38°]. White scales. Sol. ligroin and ether.

Ethyl ether EtA'. [36°]. White scales. V. sol. warm alcohol, ether, chloroform, and CS₂.

Amide C₃H₇NH₂. [108°]. Trimetric needles.

LACTIC ACID C₃H₅O₃, i.e. CH₃.CH(OH).CO₂H. *α-Oxy-propionic acid*. *Ethylidene-lactic acid*. *Fermentation lactic acid*. Mol. w. 90. S.G. ²⁰ 1.2403 (Brühl); ²⁰ 1.2485 (Mendeleëff, *C. R.* 56, 52). $\mu_D = 1.4469$. $n_D = 1.118$.

Isomerides.—Lactic acid is isomeric with hydracrylic acid, and appears to be chemically identical with sarcosolactic acid (*v. infra*).

In 1868 Wislicenus got from ethylene chlorhydrin and KCN, by saponifying the product, a lactic acid which formed a crystalline zinc salt ZnA', 2aq. He called it ethylene lactic acid, thought it was identical with Liebig's sarcosolactic acid (*A.* 128, 4). Dessios (*A.* 146, 168) said that sarcosolactic acid gave, on oxidation, malonic acid. Wislicenus held (*A.* 167, 346) that his ethylene lactic acid was not hydracrylic acid, for by the action of HI he was unable to obtain β -iodo-propionic acid. He said also that his ethylene lactic acid differed from sarcosolactic, although it accompanied sarcosolactic acid in extract of meat. Jrlenmeyer (*A.* 191, 261) showed that Wislicenus's ethylene lactic acid from glycol chlorhydrin is hydracrylic acid, and could be converted by HI into β -iodo-propionic acid. The acid accompanying sarcosolactic acid is, according to Siegfried (*B.* 22, 2711) the acetyl derivative of lactic acid.

Occurrence.—1. Discovered by Schoele in sour milk and first recognised as a peculiar acid by Berzelius.—2. In opium (Smith, *Ph.* [2] 7, 50; Buchanan, *B.* 3, 182).

Formation.—1. by the lactic fermentation of milk-sugar, cane-sugar, or glucose (*v. Fermentation*, vol. ii. p. 543).—2. By the oxidation of propylene glycol by the oxygen of the air in presence of platinum-black (Wurtz, *A.* 105, 206; 107, 192).—3. By boiling α -chloro-propionic acid with water and Ag₂O (Wurtz, *A. Ch.* [3] 59, 165; Buff, *A.* 140, 156). In like manner from α -bromo-propionic acid (Friedel & Machuca, *A.* 120, 286).—4. By the action of nitrous acid upon alanine (Strecker, *A.* 75, 27, 42).—5. By the reduction of pyruvic acid by sodium-amalgam (Wislicenus, *A.* 126, 227) or with zinc in presence of dilute acetic acid (Debus, *C. J.* 16, 260).—6. From aldehyde by combination with HCN and saponification of the resulting nitrile (Wislicenus, *A.* 128, 6; Simpson & Gautier, *A.* 146, 254).—7. By heating α -chloroacetone with a large quantity of water at 200° (Linnemann & Zotta, *A.* 159, 247).—8. By boiling glucose with aqueous NaOH (Hoppe-Seyler, *B.* 4, 346).—9. When glucose (20 g.) is allowed to stand with potash (40 g.) and water (200 c.c.) at 40° in a flask loosely plugged with cotton wool, it is converted within 24 hours into lactic acid (8 g.) and another acid, soluble in alcohol (Nencki & Sieber, *J. pr.* 132, 499). Lactic acid may possibly be thus formed in animals from sugar. The decomposition occurs even in very dilute solutions, thus even 9 g. of glucose and 9 g. of potash dissolved in 8 litres of water and kept at 35°–40° are converted in 10 days into potassium lactate. Na₂CO₃ does not decompose

sugar at 40°, nor does NH₃, but NaOH, NMe₃OH and neurine do convert it into lactic acid. Creatinine and guanidine produce no lactic acid. Milk sugar and maltose behave like glucose. Lactic acid is formed when glucose (dextrose) (1 pt.), water (10 pts.) and KOH (2 pts.) are left, even in an atmosphere of hydrogen, for 48 hours at 35°. No sugar is left (Nencki & Sieber, *J. pr.* [2] 26, 1; Kiliani, *B.* 15, 701).—10. By heating cane-sugar with baryta at 150° (Schützenberger, *Bl.* [2] 25, 289).—11. Among the products of the distillation of glycerin with KOH (Herter, *B.* 11, 1167), and formed, together with formic and oxalic acids, by boiling glycerin with potash solution (Debus, *A.* 109, 229).

Preparation.—1. The filtered solution of sour whey evaporated nearly to dryness, in strong alcohol, is mixed with alcoholic tartaric acid, as long as any precipitate of tartrate of potassium, sodium, and calcium is formed; the liquid decanted after 24 hours, and evaporated; the residue dissolved in water; the solution digested with carbonate of lead, till lead dissolves in it; the filtrate evaporated, neutralised with carbonate of barium, again filtered, and diluted with water; the whole of the barium precipitated with sulphate of zinc; and the filtrate evaporated till lactate of zinc crystallises out (Berzelius, *Lehrb.* Aug. 5, v. 231).—2. Three kilos of cane-sugar and 15 g. of tartaric acid (which serves to invert the cane-sugar) are dissolved in 13 kilos of boiling water; 1½ kilos of levigated chalk added after two days, together with 60 g. of stinking cheese, suspended in 4 kilos of sour milk (decaying cheese favours the production of lactic acid and retards its conversion into butyric acid); the mixture set aside at a temperature between 30° and 35°, and well stirred every day till, in the course of six or eight days, it is converted into a stiff paste of lactate of calcium; this paste is boiled for an hour with 15 g. of quicklime and 10 kilos of water; the solution strained through a cloth filter and evaporated to a syrup; the crystalline mass, which forms in four days, pressed, first by itself, then three or four times, after having been each time stirred up, with ½ of its weight of cold water; and the lactate of calcium thus purified is dissolved in twice its weight of boiling water. To the solution of every 32 pts. of the calcium salt there is then added a mixture of 7 pts. oil of vitriol and 7 pts. water; the lactic acid, whilst still hot, is strained through linen to separate it from sulphate of lime; the filtrate obtained from 7 pts. of oil of vitriol is boiled with 1½ pts. carbonate of zinc for a quarter of an hour (by longer boiling a very sparingly soluble basic salt is formed); the liquid is filtered boiling hot; the colourless crystalline grains of lactate of zinc, which separate on cooling, are freed from sulphuric acid by washing with cold water; and additional quantities of crystalline grains are obtained by evaporating the mother-liquor almost to the end. Lastly, 1 pt. of the zinc salt is dissolved in 7½ pts. of boiling water; sulphuretted hydrogen passed through the solution as long as sulphide of zinc is precipitated; and the filtrate boiled and evaporated on the water-bath to a syrup, whereupon 8 pts. of the zinc salt yield 5 pts. of syrupy lactic

acid (Bensch, *A.* 61, 174). By this process, 100 pts. of cane-sugar yield 117 pts. of lactate of calcium, which, if the sugar was white, is colourless, and does not require to be purified by pressure (*cf.* Engelhardt a. Maddrell, *A.* 63, 83; 70, 241; Boutron a. Frey, *J. Ph.* 27, 341).

3. Lautemann (*A.* 118, 242) recommends the following modification of Bensch's process of preparation:—Retaining the proportions of sugar, tartaric acid, milk, and cheese indicated by the latter, he takes one-third more water, uses 1,200 g. oxide of zinc (commercial zinc-white) instead of levigated chalk, and keeps the temperature as constantly as possible between 40° and 45° during the fermentation. After eight or ten days, the inside of the vessel is lined with white crystals of lactate of zinc, which can be obtained pure by one or two crystallisations from boiling water. The lactic acid prepared from the zinc salt generally contains mannite, which does not completely crystallise out from the concentrated acid. To separate this, the aqueous acid is shaken up with ether, and then the ethereal layer is pipetted off and evaporated: it then leaves pure lactic acid.—

4. The following mixture is recommended by C. O. Harz (*Vierteljahrsschrift pr. Pharm.* 20, 501); 3 pts. milk-sugar, 86 pts. ordinary water, 0.5 to 0.75 pt. flour containing a large proportion of gluten, a little beer-yeast, 6 pts. of soda-crystals, or 3 pts. of sodium bicarbonate. When the fermentation has once been set up by milk-sugar, it may be continued by addition of cane-sugar.—5. By the action of NaOH or KOH on dextrose or levulose, the operation being performed as follows:—A solution of 500 grms. of cane-sugar in 250 c.c. of water and 10 c.c. dilute sulphuric acid (3 pts. H_2SO_4 to 4 pts. H_2O) is heated to 50° in a closed vessel for 3 hrs. After cooling, 400 c.c. of aqueous NaOH (50 p.c.) is slowly added. The mixture is then warmed to 60°–70°, till it no longer reduces Fehling's solution, the calculated quantity of H_2SO_4 (same strength as before) is then added, and the Na_2SO_4 made to crystallise out by cooling and agitation. The mass is extracted with 93 p.c. spirit and filtered, the filtrate is divided into two portions, one half being neutralised with $ZnCO_3$, filtered hot and the other half added. On cooling, the zinc lactate crystallises out in a nearly pure state; the yield is 200 grms. (Kilian, *B.* 15, 699; *cf.* Hoppe-Seyler, *B.* 4, 346).

Properties.—Colourless syrup with very sour taste. Hygroscopic. Miscible with water and alcohol, sl. sol. ether. Does not solidify at –24°.

Reactions.—1. When gradually heated it gives off water at 130° leaving solid lactide. At 250° to 300° the products are CO , CO_2 , aldehyde, and lactide.—2. Dilute H_2SO_4 , at 130° gives aldehyde and formic acid (Erlenmeyer, *Z.* 1868, 843): $CH_3CH(OH)CO_2H = CH_3CHO + HCO_2H$. 3. When gently heated with conc. H_2SO_4 , it gives off CO freely (Pelouze, *A. Ch.* [8] 13; 257).—4. Boiling nitric acid forms oxalic acid.—5. Distillation with NaCl, dilute H_2SO_4 , and MnO_2 yields aldehyde and chloral (Städeler, *A.* 69, 882).—6. Distillation with MnO_2 and dilute H_2SO_4 yields aldehyde and CO_2 .—7. Fuming H_2SO_4 gives methane disulphonic acid (Strocker, *A.* 118, 291).—8. Chromic acid mixture gives

acetic acid and CO_2 (Chapman a. Smith, *Z.* 1867, 477).—9. $KMnO_4$ gives pyruvic acid.—

10. PCl_5 acting on dry calcium lactate gives chloro-propionyl chloride $CH_3CHCl.COCl$ whence water forms α -chloro-propionic acid.

11. $HIAg$ reduces it to propionic acid (Lautemann, *A.* 118, 217).—12. A concentrated solution of potassium lactate submitted to electrolysis yields aldehyde and CO_2 (Kolbe, *A.* 118, 244; Brester, *Z.* 1866, 680).—13. Distillation with quicklime yields alcohol: $C_3H_7O_2 = CO_2 + C_2H_5O$ (Hanriot, *C. R.* 101, 1156; *Bl.* [2] 45, 80).—14. Heated at 170° in a stream of gaseous HBr , or at 100° in sealed tubes with conc. $HBrAq$, it yields α -bromo-propionic acid (Kekulé, *A.* 130, 11).—15. Bromine at 100° decomposes lactic acid (Beilstein, *A.* 120, 227). Br acting on an ethereal solution of lactic acid forms tri-bromo-pyruvic ether (Wichelhaus, *A.* 143, 10; Klimenko, *J. R.* 8, 225).—16. The dry distillation of calcium lactate produces CO_2 , ethylene, propylene (Gossin, *Bl.* [2] 43, 49), acrylic acid, phenol (?) (Claus, *A.* 136, 287), and other products.—17. Distillation of calcium lactate with soda-lime yields acetic, propionic, butyric, hexoic, and other fatty acids. Heating calcium lactate with KOH at 280° yields formic, acetic, propionic, butyric, and oxalic acids (Hoppe-Seyler, *H.* 3, 352).—18. Among the products of the putrefactive fermentation of calcium lactate are hydrogen, CO_2 , acetic, propionic, butyric, and n -valeric acids and ethyl alcohol (Pasteur, *Bl.* 1862, 52; Strecker, *A.* 92, 80; Fitz, *B.* 11, 1898; 12, 479; 13, 1309).—19. Heating with m -amido-benzoic acid forms $CH_3CH(OH).CO.NH.C_6H_4.CO.H$ crystallising from water in small prisms [162°] (Pellizzari, *A.* 232, 154), which at 240 forms an anhydride CH_3CH

$\begin{array}{c} \text{CO} \\ | \\ \text{N.C}_6\text{H}_4.CO.H \end{array}$ [243°]. The 'corresponding acetyl derivative $CH_3CH(OAc).CO.NH.C_6H_4.CO.H$ melts at 148°.

Estimation.—The substance, acidified with H_2SO_4 , is extracted with ether, the ethereal solution evaporated, the residue treated with water and the aqueous solution ppd. with lead acetate and filtered. The filtrate is then ppd. with alcoholic NH_3 , and the pp. of $Pb_3O_3.2(C_2H_3O_2)$ washed with alcohol, dried, weighed, ignited, and weighed again (Palm, *Fr.* 26, 23).

Salts.—The crystalline lactates do not effloresce in the air, but give off water *in vacuo*. They are not decomposed at 150°. They are insoluble in ether and, for the most part, sparingly soluble in cold water. Ammonium salt forms deliquescent prisms, and gives off NH_3 when exposed to air.— NaA' (at 140°): amorphous, deliquescent mass, v. sol. water and alcohol, ppd. by ether from its alcoholic solution.— $Na_2O.H_2O_2$ i.e. $CH_3CH(ONa).CO_2Na$: obtained by the action of sodium on the preceding at 180°. Hard, deliquescent, brittle mass. Decomposed by cold water, with evolution of heat, into $NaOH$ and $NaC_2H_3O_2$. Absorbs CO_2 from the air, forming Na_2CO_3 and sodic lactate. Basic sodium lactate appears to dissolve without decomposition in perfectly dry alcohol. With MeI it gives NaI and $CH_3CH(OMe).CO_2Na$ (Wislicenus, *A.* 125, 49).—Potassium salt crystallises with difficulty.— BaA' , 4sq (at 100°):

large cauliflower-like bundles of rectangular needles (Hans Meyer, *B.* 19, 2454). Deliquescent, v. sol. dilute alcohol, insol. absolute alcohol and ether.— $\text{BaH}_2\text{A}'$: crystals, v. sol. water. Not altered by exposure to air.— CaA' , 5aq: small white mammillated crystals (from water or alcohol). S. 10·5 in the cold. Extremely soluble in boiling water. Sol. hot, nearly insol. cold, alcohol. At 100° it becomes CaA' , and at 280° it is converted into $\text{CaC}_2\text{H}_3\text{O}_5$ (Wurtz a. Friedel, *A. Ch.* [8] 63, 134).— $\text{CaH}_2\text{A}'$, 3aq: crystals resembling wavellite; sol. absolute alcohol (Engelhardt a. Maddrell, *A.* 66, 119).— $\text{CaK}_2\text{A}'$: octahedra. Deposits CaA' , when dissolved in warm water (Strecker, *A.* 91, 352).— $\text{CaNa}_2\text{A}'$, 2aq: granules (S.).— $\text{CaCl}_2\text{A}'$, 3aq: prisms, v. e. sol. water (E. a. M.).— $\text{Ca}_2(\text{CH}_3)_2(\text{C}_2\text{H}_3\text{O}_5)_2$, 10aq: from calcium chloride, formate, and lactate (Böttger, *A.* 188, 329). Long needles.— SrA' , 3aq: very soluble.— MgA' , 3aq: prisms, insol. alcohol, less soluble than the corresponding sarcosylate. S. 3·6 in the cold; 16·7 at 100°.— AlA' : trichlinic octahedra (Hans Meyer, *B.* 19, 2454).— $\text{AlNa}_2\text{A}'$, 5aq: rectangular prisms and tables.— FeA' , 3aq: small greenish crystals. S. 2·1 at 10°; 8·5 at 100°. Insol. alcohol.—Ferri lactate is a brown amorphous deliquescent mass, v. sol. water.— MnA' , 2aq: amethyst-coloured monoclinic crystals, m. sol. cold, v. sol. hot, water.— CoA' , 3aq: peach-blossom coloured needles, nearly insol. cold, m. sol. boiling water, insol. alcohol.— NiA' , 3aq: apple-green needles.— ZnA' , 3aq: shining crusts, or large crystals irregularly grouped. S. 1·07 at 8° (Buff, *A.* 140, 160); 1·8 at 10° (Wislicenus, *A.* 126, 228); 1·9 at 15° (Strecker, *A.* 105, 316); 16·7 at 100°. Almost insol. alcohol, which partly converts it into amorphous ZnA' , which again takes up 2aq when exposed to the air (Klimenko, *J. R.* 12, 98).— $\text{ZnA}'\cdot\text{N}_2\text{H}_4$ — $\text{ZnA}'\cdot\text{N}_2\text{H}_4$ (Lutschak, *B.* 5, 30).— $\text{ZnNa}_2\text{A}'$, 2aq.— CdA' : small needles. Anhydrous when deposited from a boiling solution. Insol. alcohol. S. 10 in the cold; 12·5 at 100°.— $\text{BiCl}_2\text{H}_2\text{O}_5$ (Brüning, *A.* 104, 194).— CuA' , 2aq: dark-blue monoclinic tables (Schabus, *J.* 1854, 405). S. 16·7 in the cold; 45 at 100°. S. (alcohol) 9 in the cold; 4 at 78°. Decomposed at 200° giving aldehyde, lactide, and CO_2 (Engelhardt, *A.* 70, 249).— $\text{CuC}_2\text{H}_3\text{O}_5$: v. sl. sol. water.— HgA' , aq: rose-coloured or crimson crystals, sl. sol. water, obtained by mixing the boiling solutions of mercurous nitrate and sodium lactate (E. a. M.). Prisms of the mercurous salt $\text{Hg}_2\text{A}'_2$ are also formed by boiling aqueous lactic acid with HgO (Brüning).— $\text{SnO}_2\text{H}_2\text{O}_5$: crystalline powder, insol. water.— PbA' : gummy; v. sol. water.— $\text{PbC}_2\text{H}_3\text{O}_5$ (Möldenhauer, *A.* 131, 333).— $\text{Pb}_2\text{A}'_2\text{O}_5$ aq: heavy granular pp., formed when lactic acid is mixed with lead acetate and alcoholic NH_3 .— UroA' : yellow crystalline crusts.— AgA' aq: silky needles. S. 5 in the cold. V. sol. hot, nearly insol. cold, alcohol.

Nitrosyl derivative

$\text{CH}_3\text{CH}(\text{ONO})\text{CO}_2\text{H}$. S.G. 1·35. Formed by dissolving lactic acid in a mixture of conc. HNO_3 and H_2SO_4 and ppg. with water (Henry, *B.* 3, 532). Thick oil. Sl. sol. water, v. e. sol. ether. Decomposes in the cold into HO and oxalic acid (Henry, *B.* 13, 1887).

Acetyl derivative $\text{C}_4\text{H}_7\text{O}_5$, i.e.

$\text{CH}_3\text{CH}(\text{OAc})\text{CO}_2\text{H}$. [187°] (Siegfried). Formed by heating ethyl lactate with AcCl and saponifying the product by heating it with water at 150° for 5 hours (Perkin, *Z.* 1861, 166; Wislicenus, *A.* 125, 60). Formed also by boiling a solution of zinc acetate and sarcosylate or lactate (Siegfried, *B.* 23, 2715). Occurs in extract of meat. Thin needles, v. e. sol. water. Inactive. Volatile with steam. Decomposed by long boiling with water into acetic and lactic acids. Bases quickly effect this decomposition. When first prepared it is soluble in alcohol, but on keeping it becomes insoluble in alcohol, does not then melt below 300°, and is saponified with great difficulty by alkalis. HI produces no β -iodopropionic acid.— BaA' , 4aq: brittle gumlike mass, v. sol. water, sol. alcohol.—Copper salt: amorphous deliquescent bluish-green mass.— ZnA' : gummy mass. Its solutions become quickly acid, from conversion into acetic acid and zinc lactate.

Benzoyl derivative $\text{C}_{10}\text{H}_{11}\text{O}_5$, i.e.

$\text{CH}_3\text{CH}(\text{OBz})\text{CO}_2\text{H}$. [112°]. S. 25 in the cold. Obtained by heating lactic acid with benzoic acid at 180° (Strecker, *A.* 80, 42; 91, 360). Formed also by the action of BzCl on calcium lactate (Wislicenus, *A.* 133, 277). Tables or needles; m. sol. boiling water, v. sol. alcohol and ether. Converted by boiling water into benzoic and lactic acids. When recrystallised from water benzoyl-lactic acid is always accompanied by an oily hydrate $\text{C}_{10}\text{H}_{11}\text{O}_5$, aq, which in dry air is slowly converted into the crystalline acids.— BaA' , 6aq: thin six-sided plates.— AgA' .

Amide $\text{C}_4\text{H}_7\text{NO}_4$, i.e. $\text{CH}_3\text{CH}(\text{OH})\text{CONH}_2$.

[74°]. Obtained by the action of gaseous or alcoholic NH_3 on lactide (Wurtz a. Friedel, *A. Ch.* [3] 63, 103). Formed also by saturating ethyl lactate with ammonia and allowing the liquid to stand (Brüning, *A.* 104, 197); and by heating ammonium lactate in a slow current of dry NH_3 at 130° (Engel, *C. R.* 98, 574). Small prisms, v. sol. water and alcohol. Does not combine with acids or bases, but is decomposed by them on boiling into NH_3 and lactic acid.

Benzoyl derivative of the amide

$\text{CH}_3\text{CH}(\text{OBz})\text{CONH}_2$. [124°]. From benzoyl-lactic ether and alcoholic NH_3 (Wislicenus, *A.* 133, 257). White needles, may be sublimed; sl. sol. water, v. sol. alcohol. Resolved by boiling KOH into lactic and benzoic acids and NH_3 . Prolonged treatment with alcoholic NH_3 forms benzamide and lactamide.

Isomeride of the amide $\text{C}_4\text{H}_7\text{NO}_4$.

Formed by heating ammonium lactate in a current of dry NH_3 at 100° (Engel, *C. R.* 98, 574). Pale amber-coloured syrup. Decomposes at 200°. In contact with water it immediately forms ammonium lactate.

Ethylamide $\text{CH}_3\text{CH}(\text{OH})\text{CO}_2\text{NH}_2$. [48°].

[260°]. From lactide and NH_4Et . Crystalline (Wurtz a. Friedel, *A. Ch.* [3] 63, 110). Decomposed by alkalis into ethylamine and lactic acid.

Anilide $\text{C}_9\text{H}_9\text{NO}_4$, i.e.

$\text{CH}_3\text{CH}(\text{OH})\text{CO}_2\text{NHPh}$. [58°]. Formed by heating lactic ether with aniline at 150° (Leipen, *M.* 9, 48). Colourless prisms; sl. sol. water, insol. Mg in, v. sol. ether, chloroform, and alcohol.

o-Toluide $C_6H_4NO_2$ [72°]. From o-toluidine and lactic ether. Crystalline powder (from benzene). Insol. ligroin (Leipen, *M.* 9, 50, 51)*

p-Toluide $C_6H_4NO_2$ i.e. $CH_3CH(OH).CO.NH.C_6H_4Me$. [102°]. From p-toluidine and ethyl-lactate. White needles. V. sl. sol. water.

Cyanamide $CN.NH(CO.CH(OH).CH_3)$. **Lacto-cyanamide**. Formed by dissolving lactide (20 g.) in a strong alcoholic solution of potassium cyanide (16 g.), passing in CO_2 to remove free alkali and evaporating to crystallisation (Mertens, *J. pr.* 125, 33). It forms a silver derivative.

Methyl ether $C_3H_5O_2$ i.e. $CH_3CH(OH).CO.Me$. (145° i.v.). S.G. $\frac{1}{4}$ 1.1180 (Schreiner, *A.* 197, 1; *B.* 12, 179). Colourless neutral liquid. Combines with $CaCl_2$. Is immediately decomposed by water.

Ethyl ether $C_4H_7O_2$ i.e. $CH_3CH(OH).CO.Et$. **Ethyl lactate**. (154.5° i.v.). S.G. $\frac{1}{4}$ 1.0546. Formed by distilling calcium lactate with $KEtSO_4$ (Strecker, *A.* 81, 247; 91, 855). Formed also by heating lactic acid (dried at 145°) with alcohol (F. a. W.) and by passing alcohol vapour into lactic acid at 175° (Wislicenus, *A.* 125, 58). Colourless liquid, immediately decomposed by water (Schreiner). Forms with $CaCl_2$ the compound $CaCl_2.4EtA'$ crystallising in granules. Chloral gives a liquid compound, whence phosphorus pentachloride forms liquid $CCl_3.CHCl.O.CHMe.CO_2Et$. S.G. $\frac{1}{4}$ 1.42 (Henry, *Bull. Acad. Roy. Belg.* [2] 37, No. 5). Lactic ether is a weak hypnotic (Pellacani & Bertoni, *C. C.* 1887, 1149).

Acetyl derivative of the ethyl ether $CH_3CH(OAc).CO_2Et$. (177°) at 733 mm. V.D. 5.20 (calc. 5.54). S.G. $\frac{1}{4}$ 1.046. From ethyl lactate and $AcCl$ (Wislicenus, *A.* 125, 58). Neutral oil, gradually decomposed by water into alcohol and $CH_3CH(OAc).CO_2H$. Miscible with alcohol and ether.

Benzoyl derivative of the ethyl ether $CH_3CH(OBz).CO_2Et$. (288° cor.). From ethyl lactate and $BzCl$ at 100°, or from silver benzoyl-lactate and EtI (Wislicenus, *A.* 133, 272). Oil, miscible with alcohol and ether. Resolved by water at 150° into lactic acid and benzoic ether. Alcoholic NH_3 gives $CH_3CH(OBz).CONH_2$.

Nitroxylderivative of the ethyl ether $CH_3CH(ONO_2).CO_2Et$. (178°). S.G. $\frac{1}{4}$ 1.153. From ethyl lactate, HNO_3 , and H_2SO_4 (Henry, *B.* 8, 532).

Butyryl derivative of the ethyl ether $CH_3CH(O.C_3H_7).CO_2Et$. (208°). S.G. $\frac{1}{4}$ 1.024. From α -chloro-propionic ether and potassium butyrate (Wurtz, *A.* 112, 235).

Isopropyl ether $CH_3CH(OH).CO_2Pr$. (167°) (Silva, *Bl.* [2] 17, 97).

Ethylidene ether $CH_3CH<\begin{smallmatrix} O \\ CO.O \end{smallmatrix}>$ (151°). Formed by heating lactic acid with acetic aldehyde at 150° (Leipen, *M.* 9, 46). Liquid, al. sol. water. Quickly decomposed by hot water into its components.

Tri-chloro-ethylidene ether $CH_3CH<\begin{smallmatrix} O \\ CO.O \end{smallmatrix}>CH.CCl_3$ [45°]. (223°). Prepared by heating syrupy lactic acid with excess of chloral for a short time at 150°, and

distilling the product with steam (Wahsch, *A.* 103, 1). Colourless crystals, readily sol. alcohol, ether, and CS_2 , insol. water.

Methyl derivative $C_3H_5O_2$ i.e. $CH_3CH(OMe).CO_2H$. The Na salt is formed, together with the methyl ether, by treating $CH_3CH(ONa).CO_2Na$ with MeI . The free acid is a syrup, volatile with steam. It forms an amorphous silver salt $C_3H_4AgO_2$, v. sol. water.

Methylether of the methyl derivative $C_4H_7O_2$ i.e. $CH_3CH(OMe).CO_2Me$. (135°–138°) (Markownikoff & Krestownikoff, *A.* 203, 343). From basic sodium lactate $CH_3CH(ONa).CO_2Na$ and MeI (Wislicenus, *A.* 125, 53).

Ethylether of the methyl derivative $C_5H_9O_2$ i.e. $CH_3CH(OMe).CO_2Et$. (135.5° i.v.). S.G. $\frac{1}{4}$ 0.9906. From α -bromo-propionic ether and $NaOMe$ (Schreiner, *A.* 197, 1). Colourless liquid, nearly insol. water.

Ethyl derivative $C_4H_7O_2$ i.e. $CH_3CH(OEt).CO_2H$. **Ethyl-lactic acid**. (195°–198°). Obtained by decomposing its ether $CH_3CH(OEt).CO_2Et$ with caustic potash or lime. Formed also, together with CH_3I , and acrylic acid, by the action of $NaOEt$ on iodoform (Butlerow, *A.* 114, 206; 118, 325; *Bl.* 1861, 9). Liquid, partly decomposed by distillation. Miscible with water, alcohol, and ether, but separated from its aqueous solution by $CaCl_2$ or Na_2SO_4 . Decomposes carbonates. Alkalis do not convert it into lactic acid and alcohol. When heated with conc. $HIAq$ there is formed lactic acid and EtI .

Salts.— CaA' , 2aq: flat prisms, v. sol. water. — AgA' : bunches of slender silky needles (from hot water).

Ethyl ether of the ethyl derivative $C_6H_{11}O_4$ i.e. $CH_3CH(OEt).CO_2Et$. (155° i.v.) (Schreiner, *B.* 12, 179). S.G. $\frac{1}{4}$ 0.9498. V.D. 5.05 (calc. 5.06). Formed by the action of $NaOEt$ on α -chloro-propionic ether (Wurtz, *A. Ch.* [3] 59, 169). Formed also by treating lactic ether with sodium and EtI (Wurtz & Friedel, *A. Ch.* [3] 63, 103). Also from silver ethyl-lactate and EtI . Colourless liquid, nearly insol. water, sol. alcohol and ether. Alkalis convert it into alcohol and ethyl-lactic acid.

Amide of the ethyl derivative $CH_3CH(OEt).CONH_2$. **Lactamethane**. (63°). (219°). Formed by allowing $CH_3CH(OEt).CO_2Et$ to stand a few days with aqueous NH_3 (Wurtz, *A. Ch.* [3] 59, 174). Broad plates, sol. water, alcohol, and ether. Decomposed by distillation with potash into NH_3 and lactic acid.

Phenyl derivative $CH_3CH(OPh).CO_2H$. **Phenoxy-propionic acid**. [113°]. Formed from α -chloro-propionic acid (25 g.), strong caustic soda (to neutralisation), and sodic phenylate (24 g.). The liquid is evaporated till it becomes thick, dissolved in water, and treated with HCl (L. Saarbach, *J. pr.* 129, 152). Glassy needles (from water). Sl. sol. cold water, volatile with steam, v. sol. hot water, alcohol, and ether. Aqueous solutions give a yellow pp. with $FeCl_3$. Its salts are soluble in water. — NaA' . Exhibits rotatory action while dissolving in water. Deliquescent. — KA' , 1½aq at 130°. — CaA' , 2aq. — AgA' : sharp needles, blackened by light.

Ethyl ether of the phenyl derivative EtA' . (244°). S.G. $\frac{1}{4}$ 1.380. Formed when an alcoholic solution of the acid is allowed to stand

More rapidly by passing HCl into such a solution.

Amide of the phenyl derivative
 $\text{CH}_3\text{CH}(\text{OPh})\text{CONH}_2$. [130°]. Formed from the ether by aqueous ammonia. Crystallises from hot water in long needles. V. sol. alcohol and ether. Dissolves in hot HCl, on cooling crystals of the hydrochloride of the amide separate.

Bromo-phenyl derivative
 $\text{CH}_3\text{CH}(\text{OC}_6\text{H}_4\text{Br})\text{CO}_2\text{H}$: *Bromo-phenoxy-propionic acid*. [106°]. Formed by the action of bromine water on a solution of phenylated lactic acid. Crystallised from alcohol. V. sol. alcohol and ether, sl. sol. water. Boiling aqueous NaOH cannot turn out the bromine, hence Br is in the benzene nucleus (Sachs, *J. pr.* [2] 21, 157).—NaA'. Deliquescent needles.

Thymol derivative
 $\text{C}_6\text{H}_3\text{PrMe.O.CHMe.CO}_2\text{H}$. Formed by heating thymol with a-chloro-propionic acid in presence of a 50 p.c. solution of KOH, acidifying with HCl, and adding ammonium carbonate (Scichilone, *C.* 12, 44). The acid from synthetical thymol crystallises in prisms [74°], v. sol. alcohol, ether, and chloroform. The acid from natural thymol crystallises in needles [48°], and forms very soluble and amorphous Ba and Ag salts.

p-Benzyl-phenyl derivative
 $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{C}_6\text{H}_4\text{O.CHMe.CO}_2\text{H}$. [102°]. From p-benzyl-phenol, KOH, and a-chloro-propionic acid (Mazzara, *C.* 12, 264).

Benzyl-p-tolyl derivative
 $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{C}_6\text{H}_4\text{Me.O.CHMe.CO}_2\text{H}$. [115°]. Formed in like manner (Mazzara). Small crystals, sl. sol. water, v. sol. alcohol and ether. Its solutions give a yellow turbidity with ferric salts and crystalline pps. with lead acetate and AgNO₃.

Allophanyl derivative
 $\text{NH}_2\text{CO.NH.CO.O.CHMe.CO}_2\text{H}$. [190°]. Formed by passing gaseous cyanic acid into an ethereal solution of lactic ether and saponifying the resulting allophanyl-lactic ether with conc. HClAq at 100° (Traube, *B.* 22, 1572). Minute colourless needles, m. sol. cold, v. e. sol. boiling, alcohol or water. When heated above 190° it splits up into lactic and cyanic acids.—AgA': white powder, decomposed by boiling water.—PbA₂: crystalline pp.

Ethyl ether of the allophanyl derivative EtA'. [170°]. Colourless needles, v. sol. hot alcohol and hot water, v. sl. sol. ether. Decomposed by alkalis into CO₂, ammonia, alcohol, and lactic acid. Ammonia yields biuret.

Isoamyl ether $\text{C}_6\text{H}_{11}\text{A}'$. [131°].

Monobasic anhydride
 $\text{C}_6\text{H}_9\text{O}_3$, i.e. $\text{CH}_3\text{CH}(\text{OH})\text{CO.O.CHMe.CO}_2\text{H}$. *Dilactic acid*. Formed when aqueous lactic acid is left for several months over sulphuric acid *in vacuo* (Wislicenus, *A.* 464, 181). Requires 1 mol. of KOH for each mol. of $\text{C}_6\text{H}_9\text{O}_3$ to neutralise it, but the neutral solution gradually becomes acid from liberation of free lactic acid, potassium lactate being also formed. By heating lactic acid at 140° this anhydride is formed together with lactide. It may also be formed from a-bromo-propionic acid and potassium lactate (Brüggen, *Z.* 1869, 338). It forms

amorphous Mg and Ca salts. The ethyl ether $\text{CH}_3\text{CH}(\text{OH})\text{CO.O.CHMe.CO}_2\text{Et}$ (o. 285°). S.G. 1.134 is formed by the action of chloro-propionic ether on potassium lactate (Wurtz & Friedel, *A. Ch.* [8] 63, 112). It is decomposed when heated with water into lactic acid and alcohol.

Di-ethyl ether of the di-basic anhydride $\text{C}_{10}\text{H}_{18}\text{O}_5$, i.e. $(\text{CH}_3\text{CH}(\text{CO}_2\text{Et}))_2\text{O}$ or $\text{CH}_3\text{CH}(\text{OEt})\text{CO.O.CHMe.CO}_2\text{Et}$. (190° *in vacuo*). Formed by treating a-chloro-propionic ether with $\text{CH}_3\text{CH}(\text{ONa})\text{CO}_2\text{Et}$ at 115° (Brüggen, *A.* 148, 224). Scarcely attacked by conc. KOHAq. Alcoholic KOH gives lactic acid and ethyl-lactic acid. NH₃ in ether forms an oily amide $\text{C}_{10}\text{H}_{18}\text{NO}_5$, decomposed by KOH giving lactic and ethyl-lactic acids.

Neutral anhydride $\text{C}_6\text{H}_8\text{O}_4$, i.e.

(255°). V.D. 4.81 (calc. 4.96) (Henry, *B.* 7, 753). Formed by the dry distillation of lactic acid (Gay-Lussac & Pelouze, *A.* 7, 43; Pelouze, *A.* 53, 116; Engelhardt, *A.* 70, 243; Wurtz & Friedel, *A. Ch.* [3] 63, 101). Prepared by passing dry air through lactic acid at 150° (Wislicenus, *A.* 167, 318). Monoclinic tables (from alcohol). May be sublimed. V. sl. sol. hot water, but gradually converted thereby into lactic acid. Bases quickly convert it into lactic acid. Ammonia gives lactamide. Ethylamine gives the ethylamide of lactic acid. $\text{CH}_3\text{CH}(\text{OEt})\text{CO}_2\text{Et}$ forms a compound $\text{C}_{10}\text{H}_{20}\text{O}_5$ (270°) decomposed by potash into alcohol and lactic acid.

Nitrile $\text{C}_6\text{H}_7\text{NO}$ i.e. $\text{CH}_3\text{CH}(\text{OH})\text{CN}$. *Aldehyde cyanhydrin*. (183°). Formed in the cold by allowing a mixture of aldehyde (1 mol.) and anhydrous HCl to stand for 9 days (Maxwell Simpson & Gautier, *Bl.* [2] 8, 277). Liquid, not solidified at -21°. Partially decomposed into its components by distillation. Miscible with water, alcohol, and ether. Aqueous KOH forms KOy and aldehyde (or aldehyde-resin). Conc. HClAq acts violently upon it; at 0° the products are lactic acid and NH₄Cl.

Sarcolactic acid $\text{C}_6\text{H}_8\text{O}_5$, i.e.

$\text{CH}_3\text{CH}(\text{OH})\text{CO}_2\text{H}$. *Paralactic acid* (Heintz, *P.* 75, 391). $[\alpha]_D = 3.5^\circ$. Occurs in muscular tissue, thymus and thyroid gland, urine after much exercise, spleen, lymphatic glands, and in pig's bile (Liebig, *A.* 62, 278, 326; Wislicenus, *A.* 167, 302; Strecker, *A.* 123, 354; Colasanti & Moscatelli, *H.* 12, 416; *G.* 17, 548; 18, 548; Marceuse, *B.C.* 1887, 92; Nebelthau, *Zeit. Biol.* 25, 123; Hirschler, *H.* 11, 41; Gleiss, *P.* 41, 59). Sarcolactic acid is absent from living blood, but occurs in blood after death (Salomon, *Virchow's Archiv.* 113, 356; cf. Berlinerblau, *C.* 1888, 757; Vissokovitch, *C.* 1888, 117). Sarcolactic acid may occur sometimes along with ordinary lactic acid as a product of fermentation (Mayer, *B.* 7, 1567). Its presence is then due to *micrococcus acidiparalactici*, which can convert glucose into sarcolactic acid (Nencki & Sieber, *M.* 10⁵ 532). Sarcolactic acid is formed in the fermentation of inositol by cheese (Helger, *A.* 160, 836). It is also formed by the action of nitrous acid on the amido-propionamide present in urine. A dextro-

rotatory lactic acid is formed by the action of *Penicillium glaucum* on ordinary ammonium acetate (Lewkovitch, *B.* 16, 2720).

Preparation.—1. Chopped flesh is exhausted with cold water; the extract mixed with baryta-water; the albumen coagulated by boiling and removed by filtration; and the clear liquid concentrated by evaporation. Sulphuric acid is added to the syrupy residuo, and it is shaken with ether, which leaves sarcocollactic acid when evaporated.—2. Extract of meat (1 pt.) is dissolved in warm water (4 pts.) and ppd. with 90 p.c. alcohol. The filtrate is evaporated to a syrup, mixed with 4 pts. of alcohol, filtered, evaporated, acidified by H_2SO_4 and extracted with ether (Klimenko, *J. R.* 12, 17; *Bl.* [2] 34, 321).

Properties.—Dextrorotatory syrup, forming levorotatory salts. Resembles ordinary lactic acid in its reactions. In a dry atmosphere it changes in the cold to a levorotatory anhydride $[\alpha]_D = c. -86^\circ$. At 140° it forms ordinary lactide, whence water produces ordinary inactive lactic acid (Strecker, *A.* 105, 313).

Reactions.—1. Hot dilute sulphuric acid splits it up into formic acid and aldehyde.—2. Chromic acid mixture gives CO_2 and acetic acid.

Salts.— $CaA', 4aq$ (Engelhardt, *A.* 65, 359). S. 8 in the cold. V. sol. boiling water and alcohol.— $CaA', 5aq$ changes into $CaA', 4aq$ on recrystallisation.— $MgA', 4aq$. More soluble in water and alcohol than ordinary magnesium lactate.— $NiA', 3aq$.— $ZnA', 2aq$. Forms more distinct crystals than ordinary zinc lactate. S. (of $ZnA', 2aq$) 5.7 at 14.5° ; the solubility of ordinary zinc lactate being 1.7 (Wislicenus). S. (98 p.c. alcohol) 104.— $ZnA', 3aq$. Ppd. by adding alcohol to an aqueous solution of the zinc salt.— $AgA' \frac{1}{2}aq$: flat needles.

Ethyl ether EtA'. $[\alpha]_D = -14.2^\circ$. From the skver salt and EtH (Klimenko).

Chloro-lactic acid v. CHLORO-OXY-PROPIONIC ACID.

Chloride of lactic acid v. Chloride of a. CHLORO-PROPIONIC ACID.

LACTIDE v. Neutral anhydride of LACTIC ACID.

LACTIM. A compound of the form

LACTIMIDE C_3H_5NO i.e.

$CH_3 \cdot CH \begin{array}{c} \text{CO} \\ \parallel \\ \text{NH} \end{array}$. $[275^\circ]$. Produced together with ethylamine and CO_2 by heating alanine in dry HCl at 190° as long as water comes off (Freu, *A.* 134, 372). The brown amorphous product is treated with lead hydroxide and H_2S and recrystallised from alcohol. Colourless needles; may be sublimed. V. sol. water and alcohol. Has a bitter taste. Its solution does not dissolve Ag_2O or give a c.p.p. with $ZnCl_2$ or $AgNO_3$.

LACTO-ALBUMEN v. MILK.

LACTO-ALBUMOSE v. MILK.

LACTO-BIONIC ACID. $C_{12}H_{22}O_{12}$. Formed by treating a solution of milk sugar (1 pt.) in water (7 pts.) with bromine (1 pt.) at ordinary temperatures for some days; the bromine is next removed by a stream of air and H_2S ; the HBr is

removed with white lead followed by Ag_2O and the metals with H_2S ; on treating the syrup so obtained with glacial acetic acid the lacto-bionic acid is left. The product is purified by conversion into lead salt, with specially prepared basic lead acetate, and decomposition of the same with H_2S (Emil Fischer & Jacob Meyer, *B.* 22, 362). Colourless syrup of strong acid reaction, v. sol. water, v. sl. sol. alcohol, insol. ether. Shows no tendency to crystallise. Does not reduce alkaline copper solutions even on boiling. On warming a short time with dilute mineral acids it splits up into galactose and gluconic acid.

LACTOCYANAMIDE v. LACTIC ACID, p. 112.

LACTONES. Anhydrides of oxy-acids formed by elimination of water between the hydroxyl and carboxyl groups, both being in the same carbon chain. The name is derived from lactide which, until its vapour density had been determined, was written $CH_3 \cdot CH \begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{CO} \end{array}$. Lactones are usually derived from γ - or from δ -oxy-acids. The formula $R''R'C \begin{array}{c} \text{CH}_2 \cdot \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{O} \cdot \text{CO} \end{array}$ represents a γ -lactone, while

$R''R'C \begin{array}{c} \text{CH}_2 \cdot \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{O} \cdot \text{CO} \end{array} \text{CH}_2$ is a δ -lactone (Fittig, *A.* 200, 21; 203, 67; 216, 52).

Formation.—1. γ -Oxy-acids split up in the cold, and immediately on heating their aqueous solution into water and a γ -lactone.—2. Formed by boiling their carboxylic acids with dilute H_2SO_4 (Erdmann, *A.* 228, 176).—3. From ethers of γ -oxy-acids on distillation, alcohol being split off, e.g. oxy-iso-caproic ether (Bredt), oxy-valeric ether (Kissling).—4. From unsaturated acids (v. *A.* 227, 8, 26), e.g.:

Properties.—Volatile liquids, neutral to litmus. Volatile with steam.

Reactions.—1. γ -Lactones do not take up water to form an oxy-acid by mere boiling. On the other hand most δ -lactones in presence of water, cold or hot, are partially converted into acid, and tend to assume equilibrium with 65 p.c. of lactone to 35 p.c. of acid (Fittig & Wolff, *A.* 216, 137; Hantzsch, *A.* 222, 28).—2. All lactones are converted into salts of the corresponding oxy-acids by boiling with aqueous solutions of alkalis, alkaline earths, and sometimes even with $CaCO_3$ (Fittig, *A.* 208, 116).—3. All lactones form compounds with NH_3 , which easily split up into their components (Wolff, *A.* 229, 278). These compounds are probably acid amides.—4. No lactone at present known reacts with hydroxylamine, but a few aromatic lactones readily react with phenylhydrazine (e.g. phthalide). Hence the fact of an oxygen compound reacting with phenylhydrazine cannot be taken (as previously assumed) as a proof of its aldehydic or ketonic nature. This can only be proved by its behaviour towards hydroxylamine (V. Meyer & Münchmeyer, *B.* 19, 1766). The compound formed with phthalide appears to be $HO \cdot CH_2 \cdot C_6H_4 \cdot CO \cdot NH_2 \cdot HPh$ being formed by direct addition (Wislicenus, *B.* 20, 401).—5. Lactones (1 mol.) appear to react with oxalic ether (1 mol.) in presence of $NaOEt$

(1 mol.). Phthalide gives $C_{11}H_{12}O_5$ [122°] and valerolactone also gives a crystalline compound (Wislicenus, B. 20, 2061).

Lactones are for the most part described in this Dictionary under the oxy-acids of which they are the anhydrides.

LACTONIC ACID v. GALACTONIC ACID.

Lactonic acids. Acids which are at the same time lactones. When warmed with alkalis they give rise by assimilation of water to acids of higher basicity.

LACTONITRILE v. Nitrile of LACTIC ACID.

LACTO-PROTEIN v. MILK.

LACTOSE or *Milk sugar* v. SUGAR and MILK.
LACTOSIN $C_{36}H_{62}O_{31}$. Occurs in the roots of all the caryophyllaceae, being most conveniently obtained from *Silene vulgaris* (A. Meyer, B. 17, 685). White amorphous powder (anhydr.), $[\alpha]_D = +168$; or small glistening crystals $(+H_2O)$, $[\alpha]_D = +211.7$. It forms gummy solutions with water, but is sparingly soluble in alcohol. The aqueous solution of the crystallised lactosin gives no pps. with neutral or basic lead acetate, although a pp. is produced by lead acetate and NH_3 . Fehling's solution is not reduced on short boiling. By boiling with dilute H_2SO_4 it is inverted into lactose and a new sugar.

LACTUCARIUM. A brownish viscid substance obtained by evaporating juice which exudes from incisions in the leaves and stem of certain species of lettuce, especially *Lactuca virosa*. It has an odour resembling opium and acts as a narcotic. According to Ludwig (Ar. Ph. [2] 7, 129) it contains (50 p.c. of) 'lactucine' $C_{46}H_{86}O_{16}$, a crystalline substance [150°-160°] soluble in boiling alcohol, 'lactucic acid,' lactucin, a wax, and oxalic acid. According to Hesse (A. 234, 243) lactucarium contains the acetyl derivatives of (a)- and (β)-lactuceryl.

LACTUCERIN $C_{16}H_{31}O_5$ (L.) or $C_{16}H_{31}O_5$ (K.), or $C_{16}H_{31}O_5$ (H.). *Lactucine*. [210°]. Obtained by washing lactucarium with benzene and extracting the residue with boiling alcohol; the crystals obtained may be purified by shaking their ethereal solution with aqueous KOH, and ppg. by the addition of alcohol and water (Lenoir, A. 60, 83; Kassner, A. 238, 220). Lactucerin so prepared forms minute white needles [200°], but after sublimation in CO_2 it melts at 210°. On fusion with KOH it gives lactucol $C_{16}H_{32}O$, hydrogen, and acetic acid. It is dextrorotatory. According to Hesse, lactucerin consists of the mono-acetyl derivatives of (a)- and (β)-lactuceryl. From the milk juice of *Lactuca canadensis*, by crystallising from hot alcohol. Flowers (Ph. [3] 10, 44) obtained a 'lactucerin' [89°] crystallising in colourless needles.

Lactucine $C_{16}H_{31}O_5$ (?). [236°]. Microscopic needles. Insoluble in water, difficultly soluble in alcohol. Occurs in French lactucarium from *Lactuca albisima*, from which it is extracted with 90 p.c. alcohol. Acetic anhydride does not act upon it even at 200°. By distillation with P_2S_5 it gave a hydrocarbon of the constitution $C_{16}H_{32}$, boiling between 247°-252° (Franchimont, B. 13, 10).

Lactucol $C_{16}H_{32}O$. [162°]. Obtained by fusing lactucerin with KOH (Kassner, A. 238, 224). Needles. Dextrorotatory; $[\alpha]_D = +48$.

Acetyl derivative $C_{17}H_{33}AcO$. [200°].

Like lactucol and lactucerin its solutions in ether, chloroform, and CS_2 are dextrorotatory; $[\alpha]_D = +68$.

(a)-**LACTUCEROL** $C_{16}H_{32}O$. [166°-181°]. Obtained by exhausting lactucarium with ligroin and extracting the residue with alcohol. The crystals so obtained are saponified by alcoholic potash, and the product ppd. with water. The pp. is recrystallised from alcohol, from which (a)-lactuceryl separates first (Hesse, A. 234, 245; 244, 268).

Properties.—Crystallises from 90 p.c. alcohol in silky needles (containing 2aq). From chloroform or ether it separates in anhydrous crystals. Insol. water and alkalis. It melts at 162°, but after purification by conversion into its di-acetyl derivative and saponification of the product its melting-point is higher. Conc. H_2SO_4 colours its solution in chloroform red. It absorbs Br with evolution of HBr. It is dextrorotatory; in a 2.3 p.c. solution in chloroform $[\alpha]_D = -76.2$ at 15°. It may be distilled in a current of CO_2 .

Acetyl derivative $C_{16}H_{32}AcO$. [202°-207°]. Occurs in lactucarium, and is formed by heating (a)-lactuceryl for a short time with Ac_2O at 80°. Small plates, m. sol. cold alcohol, v. sol. ether. Dextrorotatory.

Di-acetyl derivative $C_{16}H_{32}Ac_2O$. [198°-200°]. From (a)-lactuceryl and Ac_2O by boiling for 2 hours. Satiny plates. In a 1 p.c. solution in chloroform $[\alpha]_D = +63.6$ at 15°.

Di-propionyl derivative $C_{16}H_{32}(C_2H_5O)_2$. [152°]. Minute needles (from alcohol), v. e. sol. $CHCl_3$ and ether.

Di-benzoyl derivative $C_{16}H_{32}Bz_2O_2$ [156°]. White crystals, insol. water, v. sol. ether and chloroform, sl. sol. alcohol. Saponified by alcoholic potash.

(β)-**Lactuceryl** $C_{16}H_{31}O_2$. $[\alpha]_D = -38$ at 15° in a 4 p.c. solution in chloroform. Occurs as a mono-acetyl derivative in lactucarium, and separated from its (a)-isomeride by crystallisation from alcohol. Long silvery needles (from ether or chloroform). Separates from alcohol as a gelatinous mass (containing 2aq). More soluble in alcohol, and less dextrorotatory than its isomeride.

Acetyl derivative $C_{16}H_{31}AcO$. [230°]. Plates (from alcohol). Less sol. alcohol and ligroin than its isomeride.

LACTUCIC ACID. Obtained from the juice of *Lactuca canadensis* after separating 'lactucerin,' adding water, ppg. with lead acetate, decomposing the lead salt with H_2S and evaporating (Flowers, Ph. [3] 10, 44). Brownish-green amorphous substance, with acid, bitter taste. Sol. alcohol, insol. petroleum spirit, ether, and chloroform. Ludwig (J. 1847, 824) and Wals (N. Jahr. Pharm. 15, 118) obtained a substance $(C_{16}H_{31}O_5?)$ called lactucic acid by triturating lactucarium (1 pt.) with dilute H_2SO_4 (1 pt.), adding alcohol (5 pts. of 84 p.c.), filtering, shaking the filtrate with slaked lime, decolourising with animal charcoal, evaporating, and crystallising the residue from boiling water. Light yellow amorphous mass, gradually becoming crystalline. Its solutions are coloured wine-red by alkalis, and reduce boiling Fehling's solution.

LACTUOLIN $C_{16}H_{31}O_5$, or $C_{16}H_{31}O_5$, or $C_{16}H_{31}O_5$. S. 1-25 in the cold. Occurs in the juice of common lettuce (*Lactuca sativa*) and of *Lactuca*

altissima (Aubergier, *B. J.* 24, 522; *A.* 44, 299; Walz, *A.* 82, 85; *N. Jahr. Pharm.* 15, 118; Ludwig a. Kromayer, *Ar. Ph.* [2] 111, 1; Kromayer, *Ar. Ph.* [2] 105, 9; Buchner, *Rep. Pharm.* 43, 1; Flowers, *Ph.* [3] 10, 44). Obtained by macerating the dried juice with hot water (1½ pt.) for four days, pressing the mass, boiling the residue with water, and ppg. the filtrate with lead subacetate, removing excess of lead from the filtrate by H_2S , and evaporating. Pearly scales (from alcohol). M. sol. alcohol and $HOAc$, sl. sol. ether. Conc. HNO_3 turns it brown. Its solutions are not ppd. by ordinary reagents.

LACTUCOPICRIN $C_{44}H_{84}O_{21}$. An amorphous very bitter substance which remains in the mother-liquor in the preparation of lactucin (Kromayer, *Die Bitterstoffe*, 1861; Flowers, *Ph.* [3] 10, 222). Sol. water and alcohol, its solutions not being ppd. by lead salts.

LACTURAMIC ACID v. URAMIDO-PROPIONIC ACID.

LACTYL CHLORIDE is the chloride of α -CHLORO-PROPIONIC ACID.

LACTYL-THIO-UREA

From thio-urea and α -chloro-propionic ether at 100° (Freitag, *J. pr.* [2] 20, 380). Crystalline.

LACTYL-UREA $C_4H_8N_2O_2$, i.e.

Methyl-hydantoïn. [140°] (H.); [145°] (Urech, *B.* 6, 1113). Formed by treating aldehyde-ammonia with crude KCN and hydrochloric acid $CH_3CH(OH)NH_2 + HCN + HClO = NH_2 + C_2H_5N_2O_2$ (Heintz, *A.* 169, 120). Formed also by heating uramido-propionic acid. Prisms, or cauliflower-like tufts (containing aq); v. sol. water and alcohol, nearly insol. ether. May be sublimed. Tastes bitter. Neutral in reaction. Boiling baryta water converts it into uramido-propionic acid. Heating with barium hydrate at 100° - 140° gives alanine. Pure HNO_3 gives a quantitative yield of a nitro-derivative, but no gas is evolved (Franchimont, *R. T. C.* 6, 217).— $AgO, H_2N_2O_2$, formed by treating lactyl-urea with moist Ag_2O . Insol. water, sol. NH_4Aq . Ppd. as a white powder by adding HNO_3 to its ammoniacal solution.

LÆVULAN $C_6H_{12}O_6$. [250°]. [α] $_D = -221^\circ$. Occurs in an impure condition in the residues obtained from desugaring molasses by Steffen's process (Lippmann, *B.* 14, 1509). White amorphous powder. Sol. hot water, the solution gelatinises on cooling. By long boiling it becomes much more soluble and loses its power of gelatinising. Insol. alcohol. It does not reduce Fehling's solution but produces a blue pp. By HNO_3 it is oxidised to mucic acid. Dilute H_2SO_4 at 120° converts it into levulose.

LÆVULIN $C_6H_{12}O_6$ (dried at 110°). A substance resembling dextrin, obtained in the juice of the tubers of the Jerusalem artichoke (*Helianthus tuberosus*) and of *Dahlia variabilis*, and in oak bark (Ville a. Joulie, *Bl.* [2] 7, 262; Popp, *A.* 156, 181; Dieck a. Tollens, *A.* 198, 228; *B.C.* 1879, 275; Etti, *B.* 14, 1826; Lefranc, *J. Ph.* [5] 2, 216; Reidemeister, *J. Th.* 1881, 68). Prepared by ppg. the juice of artichokes with lead acetate, filtering, removing excess of lead by

H_2S , neutralising with $MgCO_3$, filtering and evaporating. The residue is extracted with alcohol, until it is optically inactive. It is then extracted with absolute alcohol, which leaves inulin undissolved, and ppg. with ether.

Properties.—Amorphous deliquescent mass; optically inactive, but becomes levorotatory on boiling with dilute HCl , being split up into levulose and glucose. V. sol. water and dilute alcohol, sl. sol. absolute alcohol, insol. ether. Has an insipid taste. Turns brown at 140° forming caramel. Not ppd. by lead subacetate. Reduces Fehling's solution after long boiling. Dilute HNO_3 gives oxalic acid and saccharic acid. Alkalis do not turn it brown. First hydrolysed by yeast and then undergoes alcoholic fermentation. Levulin prevents the ppn. of ferric and cupric salts by alkalis. $AgNO_3$ gives a white pp. blackened on heating.— $K_2C_2H_3O_4$: ppd. by adding alcoholic KOH to its alcoholic solution.— Ba_2O_2, H_2O, aq : amorphous. $Pb_2C_2H_3O_4, aq$: amorphous; ppd. by adding an alcoholic solution of lead subacetate to an alcoholic solution of levulin.

LÆVULINIC ACID v. β -ACETYL-PROPIONIC ACID.

LÆVULOSE v. SUGAR.

LANTHANUM. Lat. At. w. 138.2. Mol. w. unknown. S.G. 6.163. Melts between M.P. of Sb (450°) and that of Ag (950°) (Hillebrand a. Norton, *P.* 156, 466). S.H. .04485 (H. a. N., *P.* 158, 71). S.V.S. 22.4. Chief lines in emission-spectrum 5183, 4921, 4920 in the green; 4824, 4655, 4558 in the blue; 4522, 4330, 4268 in the indigo; 4238, 4196, 4086, 4077 in the violet (Thalén). In 1803 Klaproth separated a new earth from a Swedish mineral; the earth was examined by Hisinger and Berzelius and called by them ceria (from the planet Ceres then recently discovered). In 1839 Mosander showed that ceria contained two oxides (*P.* 46, 648): the name ceria was retained for one, and the other was given the name lanthana (*λανθάνει* = to be concealed). In 1841 Mosander discovered that lanthana was a mixture of two oxides (v. *P.* 60, 297); one of these he called lanthana and the other didymia (*δίδυμος* = twofold).

Occurrence.—As silicate, with silicates of Ce and Di, in cerite, gadolinite, orthite, &c. (Rammelsberg, *P.* 107, 631). Lanthanite, from Bethlehem in Pennsylvania, U.S., is a carbonate of La and Di (Lawrence Smith, *Am. S.* [2] 18, 378). La-containing minerals occur in small quantities in a few localities.

Preparation.—The mixed oxides of Ce, La, and Di are separated from cerite by treatment with H_2SO_4 , &c., as described under CERITE (vol. i. p. 723); the oxides are dissolved in HNO_3Aq , the solution is evaporated to dryness the residue is heated to full redness until pale yellow, and then treated with boiling dilute HNO_3Aq in which nitrates of La and Di dissolve while basic Ce nitrate remains insoluble. There are various ways of separating La from Di in the nitric acid solution. The hydrated oxides may be obtained by ppn. with NH_4Aq ; the pp. is dissolved in H_2SO_4Aq , and the mixed sulphates are obtained by crystallisation; the sulphates are dried and powdered; 1 part is dissolved in small successive portions in 6 parts

water at 2° - 8° ; the solution is then heated to $c. 40^{\circ}$ when $\text{La}_2(\text{SO}_4)_3$ separates nearly free from $\text{Di}_2(\text{SO}_4)_3$. The $\text{La}_2(\text{SO}_4)_3$ may be purified by re-solution in ice-cold water and heating to 40° , the operations being repeated until the sulphate is perfectly white and shows no Di lines in the spectrum. Or the solution of $\text{La}_2(\text{SO}_4)_3$ may be pptd. by oxalic acid, the pp. strongly heated, dissolved in HNO_3Aq , and fractionally pptd. by NH_4Aq ; the ppn. must be effected from very dilute solutions by means of very dilute NH_4Aq ; the first third of the pp. contains most of the Di oxide; ppn. is continued so long as the pp. shows Di lines in the spectrum. This method gives good results when comparatively much La is present (Mosander, *L.c.*; Bunsen & Jögel, *P.* 155, 377), but it is slow and laborious. Marignac (*J. pr.* 43, 406) adds excess of HNO_3Aq to the solution of the nitrates of La and Di, heats, and adds oxalic acid; the pp. dissolves; when crystallisation begins the solution is allowed to cool, and is then poured off from the pp. which is rich in Di oxalate; these operations are repeated; a very acid solution of La salt is finally obtained from which NH_4Aq ppt. $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$. This method is recommended when much Di is present with little La.

The method of Von Welsbach (*Sitz. W.* 92 [2nd part], 817) was found very good by Robinson (*priv. comm.*). A large quantity of the mixed nitrates of Ce and La obtained from *cerite* after separating basic Ce nitrate (v. vol. i. p. 723) is mixed with the necessary quantity of NH_4NO_3 , about $\frac{1}{10}$ th part conc. HNO_3Aq is added, and the liquid is evaporated until small crystals appear on the surface, a little water is then added, and crystallisation is allowed to proceed for about 24 hours; the crystals are drained and washed with a little HNO_3Aq which is added to the mother-liquor; the mother-liquor is evaporated and crystallised; the liquor from this is again evaporated, and so on until 6-8 fractions are obtained. The first fraction contains almost all the La. By fractionating the middle fraction, placing the first fractional pp. in the former first fraction, and repeating this process a few times, pure $\text{La}(\text{NO}_3)_3$ is obtained. For other methods of separating La salts from salts of Ce and Di v. Hermann, *J. pr.* 82, 385; Erk, *Z.* [2] 7, 100; Cleve, *Bl.* [2] 21, 196, 246.

La_2Cl_6 is obtained by dissolving the pp. of $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ (obtained as described above) in HClAq , adding NH_4Cl , evaporating to dryness, and heating strongly in a covered crucible. By reducing La_2Cl_6 by heating with K and washing out KCl in alcohol, metallic La is obtained. Hillebrand & Norton obtained approximately pure La by electrolysis La_2Cl_6 covered with a fused mixture of KCl and NaCl, using a thick iron wire as negative electrode and a battery of 4 Bunsen's cells (*P.* 156, 466; cf. Bunsen, *P.* 155, 633).

Properties and Reactions.—White metal; fairly malleable and ductile; rather harder than Ce. Oxidises rapidly in dry air, but burns only at temperature considerably higher than that at which Ce burns. Decomposes cold water slowly, hot water rapidly. Easily dissolved by acids, including cold conc. HNO_3 , which scarcely acts on Ce.

The atomic weight of La has been deter-

mined (1) by converting the oxide into the sulphate and *vice versa* (Rammelsberg, *P.* 55, 65; Marignac, *A. Ch.* [3] 27, 228; [4] 80, 67; Holzmänn, *J. pr.* 75, 848; Czudnowicz, *J. pr.* 80, 33; Hermann, *J. pr.* 82, 895; Zachiescho, *J. pr.* 104, 174; Erk, *Z.* [2] 7, 106; Cleve, *Bl.* [2] 81, 198; Brauner, *C. J.* 41, 75; Crookes, *Pr.* 38, 414; (2) by analysing La iodate (Holzmänn, *J. pr.* 75, 349); (3) by estimating Cl in La chloride (Hermann, *J. pr.* 82, 395); (4) by converting La carbonate into oxide (Hermann, *L.c.*); (5) by determining S.H. of La (Hillebrand & Norton, *P.* 158, 71); (6) by considering the chemical relations of La with other elements in the light of the periodic law.

The at. w. of La was taken for many years as c. 92.2; the oxide was formulated LaO and the chloride LaCl_2 . Mendeleeff (*v. O. N.* 41, 49) proposed to multiply the usually accepted at. w. by 2, and to regard the oxide as LaO_2 ; by doing this he placed La in Group IV. along with Ce. As the properties of La salts were not much known when Mendeleeff's memoir was published, he did not strongly press the arguments in favour of the position assigned by him to La. Fuller investigation showed that the usually accepted at. w. of La should be increased by one half, that the oxide should be regarded as similar to the oxides of the earth-metals (M_2O_3), and that La should be placed in Group III. along with Al, Ga, Sc, &c. (*v. EARTH METALS OF THE*, vol. ii. p. 424).

La is distinctly metallic in its chemical relations; it forms the oxide La_2O_3 and there are indications of the existence of a higher oxide; the chloride is La_2Cl_6 or LaCl_3 . La forms several

salts of the form LaX_3 , $\text{X} = \text{NO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{8}$

&c.; a few double salts and one or two basic salts are known. The investigation of the La compounds shows that this metal is to be placed with the metals of the earths (Group III.); it is more closely related to the even-series members of the group (Sc, Y, and Yb) than to the odd series members (Al, Ga, In, Tl). The strongly basic character of La_2O_3 marks the connection of La with the alkaline earths and alkali metals. The examination of La compounds is yet far from complete (*cf. METALS, RARE*).

Detection and Estimation.—Most of the La salts are colourless; the soluble salts have an astringent, sweetish taste; solutions of La salts do not show any absorption-bands. Alkalis, NH_4HS , and KCN, form gelatinous pps. insoluble in excess of pptant. Alkali carbonates ppt. $\text{La}_2(\text{CO}_3)_3$; BaCO_3 forms a pp. without warming; $\text{H}_2\text{C}_2\text{O}_4$ forms a white pp. at first curdy, then crystalline, more soluble in acids than the oxalates of Ce and Di; $\text{Na}_2\text{S}_2\text{O}_3$ does not produce any pp. La salts do not colour beads of borax or microcosmic salt.

• La may be estimated as La_2O_3 or $\text{La}_2(\text{SO}_4)_3$. La_2O_3 is obtained (1) by ppg. with NH_4Aq , washing as rapidly as possible with water containing NH_3 (to prevent formation of La_2CO_3 and partial solution of La), solution in HNO_3Aq , re-ppn. by NH_4Aq , washing with NH_4Aq , and strongly heating; (2) by ppg. $\text{La}_2(\text{C}_2\text{O}_4)_3$ by addition of $\text{H}_2\text{C}_2\text{O}_4$ and standing, washing, and heating to white heat. $\text{La}_2(\text{SO}_4)_3$ is obtained by ppg. with

NH_4Aq , as above, dissolving in warm dilute $\text{H}_2\text{SO}_4\text{Aq}$, evaporating to dryness at 100° , and gradually heating to redness.

Lanthanum, arsenate of. $\text{La}_2(\text{HASO}_4)_3$; and arsenite of, $\text{La}_2(\text{HASO}_3)_3$; v. Smith, *A.* 191, 331.

Lanthanum, borate of ($?2\text{La}_2\text{O}_3 \cdot \text{B}_2\text{O}_3$); obtained, along with crystals of La_2O_3 , by dissolving La_2O_3 in molten borax (Nordenskjöld, *J. pr.* 85, 431).

Lanthanum, bromide of. $\text{La}_2\text{Br}_6 \cdot 14\text{H}_2\text{O}$, or $\text{LaBr}_3 \cdot 7\text{H}_2\text{O}$. Colourless crystals, e. sol. water or alcohol; obtained by dissolving $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HBrAq and evaporating (Cleve, *Bl.* [2] 39, 151; 43, 56). By the action of Br in vapour on La_2O_3 , the oxybromide LaOBr is obtained (Frerichs a. Smith, *A.* 191, 331). Double salts are described by Cleve (l.c.):— $\text{La}_2\text{Br}_6 \cdot 2\text{AuBr}_3 \cdot 18\text{H}_2\text{O}$; $\text{La}_2\text{Br}_6 \cdot 3\text{ZnI}_2 \cdot 27\text{H}_2\text{O}$; also by P. a. S. (l.c.); $\text{La}_2\text{Br}_6 \cdot 3\text{NiBr}_2 \cdot 18\text{H}_2\text{O}$; and $\text{La}_2\text{Br}_6 \cdot 3\text{ZnBr}_2 \cdot 39\text{H}_2\text{O}$.

Lanthanum, carbide of. A carbide of La is said to be produced by heating the oxalate or formate in absence of air; it is described as similar to, but more easily acted on by acids than, Ce carbide (Delafontaine, *C. N.* 11, 253).

Lanthanum, chloride of. La_2Cl_6 , or LaCl_3 . A white crystalline mass, e. sol. water or alcohol. Obtained by adding NH_4Cl to a solution of $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq , evaporating to dryness, and heating in a closed crucible until all NH_4Cl is volatilised (Hermann, *J. pr.* 82, 406; Hillebrand a. Norton, *P. M.* 23, 241). Mosander (*P. M.* 23, 241) says that LaCl_3 can be obtained by evaporating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq to dryness, and heating the residue in a stream of HCl gas.

By slowly evaporating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in HClAq , large colourless triclinic crystals of $\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$ are obtained. Double salts are described by Smith (*A.* 191, 331), and Cleve (*Bl.* [2] 21, 196; 34, 151):— $\text{M}_3\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$; $\text{M}_2\text{PtCl}_6 \cdot 26\text{H}_2\text{O}$; $\text{M}_3\text{AuCl}_6 \cdot 21\text{H}_2\text{O}$; $\text{M}_2\text{AuCl}_6 \cdot 20\text{H}_2\text{O}$ ($\text{M} = \text{La}, \text{Ce}$).

Oxychlorides are obtained by heating the hydrated chloride in air, and by the action of Cl on La_2O_3 (v. LANTHANUM, OXYCHLORIDES OF).

Lanthanum, chromate of. $\text{La}_2(\text{CrO}_4)_3 \cdot 8\text{H}_2\text{O}$; v. Smith, *A.* 191, 355.

Lanthanum, cyanide of. LaCy_3 ; v. vol. ii. p. 341.

Lanthanum, fluoride of. $\text{La}_2\text{F}_6 \cdot \text{H}_2\text{O}$. A gelatinous pp. by adding HFAq to solution of La acetate (Cleve, *Bl.* [2] 39, 151; 43, 56). From solution of La sulphate, Smith obtained a pp. of $\text{La}_2\text{F}_6 \cdot 8\text{HF}$ (*A.* 191, 331). According to Marignac, H_2SiF_6 ppts. La_2F_6 from La salts (*J. pr.* 43, 406).

Lanthanum, hydroxide of. $\text{La}_2\text{O}_3 \cdot \text{H}_2\text{O}$, or LaO_2H ; may also be regarded as hydrated oxide $\text{La}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$. A white gelatinous pp. by adding KOH or NaOH to solution of a La salt (NH_4Aq ppts. basic compounds). Also produced by action of warm water on La_2O_3 . $\text{La}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is a strongly basic hydroxide; it turns red litmus blue, decomposes NH_4ClAq on warming with evolution of NH_3 , absorbs CO_2 from the air; reacts with acids to form salts

LaX_3 ($\text{X} = \text{NO}_3, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$, &c.). Thomsen gives

the heat of neutralisation with $\text{H}_2\text{SO}_4\text{Aq}$ and HClAq as $[\text{La} \cdot \text{O} \cdot \text{H} \cdot 3\text{H} \cdot \text{SO} \cdot \text{Aq}] = 82,320$; $[\text{La} \cdot \text{O} \cdot \text{H} \cdot 6\text{HClAq}] = 74,970$ (*Th.* 1, 875). •

Lanthanum, haloid compounds of. LaF_3 , LaCl_3 , and LaBr_3 have been isolated; the formulae may be written La_2F_6 , &c., as none of these compounds has been gasified. All form hydrates, and all combine with haloid compounds of Au and some other heavy metals to form double salts. Oxychlorides and oxybromides, LaOX , are known.

Lanthanum, iodide of. LaI_3 has not been isolated, but the double salt $2\text{LaI}_3 \cdot 3\text{ZnI}_2 \cdot 27\text{H}_2\text{O}$ is described by Frerichs a. Smith (*A.* 191, 355).

Lanthanum, oxides of. Only one oxide, La_2O_3 , is known with certainty; there are indications of the existence of an oxide containing more O.

LANTHANUM SESQUIOXIDE, La_2O_3 . Obtained by strongly heating $\text{La}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, or the oxalate, or any La salt the acid of which is volatilisable. Forms a white, amorphous, infusible powder, S.G. 6.48–6.53 (Cleve, l.c.; Nilson a. Pettersson, *B.* 13, 1464). S.H. 5749 (N. a. P., l.c.; v. also *P.* 31, 46). Diamagnetic (N. a. P., l.c.). Combines with water to form $\text{La}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ (v. LANTHANUM, HYDROXIDE OF). Easily sol. in acids. Nordenskjöld (*J. pr.* 85, 431) obtained La_2O_3 in lustrous rhombic crystals, $a:b:c = 5658:1:6863$, S.G. 5.296, by dissolving the amorphous oxide in borax in a porcelain-oven; the crystals did not directly combine with water, but were easily sol. in acids. The great infusibility of La_2O_3 , and its power of emitting white light when strongly heated, render it useful as a light-giver; Von Welsbach has patented an arrangement whereby La_2O_3 is heated in the flame of a Bunsen lamp and emits a clear white light (English Patent, 15,286, July 1886).

LANTHANUM PEROXIDE. According to Mosander (*P. M.* 23, 241) a peroxide of La is ptd. by adding BaO_2 to a neutral La salt; on drying it loses O. Hermann (*J. pr.* 82, 397) says that a peroxide is obtained by heating oxalate, nitrate, or carbonate of La in the air; it dissolves in HClAq with evolution of Cl; heated in H it yields La_2O_3 . Zschiesche (*J. pr.* 104, 74) was unable to confirm Hermann's observations. Cleve (*Bl.* [2] 43, 56) by ppg. La salts by alkali and $\text{H}_2\text{O}_2\text{Aq}$ obtained an oxide to which he assigned the composition La_2O_6 .

Lanthanum, oxybromide of. LaOBr . Obtained by the action of Br vapour on heated La_2O_3 (Frerichs a. Smith, *A.* 191, 331).

Lanthanum, oxychlorides of. LaOCl and $\text{La}_2\text{O}_2\text{Cl}_2$ ($= 3\text{La}_2\text{O}_3 \cdot \text{La}_2\text{Cl}_6$). The former is a greyish mass, unchanged by water, obtained by heating La_2O_3 in Cl to 200° (Frerichs a. Smith, *A.* 191, 331; Cleve, *Bl.* [2] 39, 151; 43, 56). The latter is obtained by heating $\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$ and washing the residue with water (Hermann, *J. pr.* 82, 385).

Lanthanum, salts of. La forms one series of salts, LaX_3 , where $\text{X} = \text{NO}_3, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}$, &c. Most

of the La salts are colourless; those which are soluble have a sweetish astringent taste. The salts of volatilisable acids yield La_2O_3 when strongly heated. La_2SO_4 combines with the alkali sulphates, but the products are not alums. A good many double La salts are known; a few basic salts have been isolated. The following are the chief La salts: arsenate, arsenite, borate,

bromate, carbonate, chlorate, chromate, hypochlorite, iodate, molybdate, nitrate, perchlorate, periodate, phosphates, phosphite, selenate, selenite, silicate, sulphates, sulphites, thiosulphates, tungstate; v. CARBOATES, NITRATES, SULPHATES, &c.

Lanthanum, sulphide of. La_2S_3 . Red-yellow, microscopic crystals; obtained by the action of 8 parts Na polysulphide with 1 part La_2O_3 , and washing with water (Beringer, A. 42, 134). Mosander obtained a greyish powder by heating La_2O_3 in CO , laden with CS_2 (P. 60, 297); and by a similar reaction Frerichs & Smith (A. 191, 655) obtained La_2S_3 as a brownish-grey powder, soluble in acids with evolution of H_2S , decomposed by water to La_2O_3 and H_2S . Didier (C. R. 100, 1461) obtained a similar body by heating La_2O_3 in H_2S gas. M. M. P. M.

LANTHOPINE $\text{C}_{15}\text{H}_{21}\text{NO}_4$. [c. 200°]. A base homologous with papaverine, occurring in opium (Hesse, A. 153, 57; Suppl. 8, 271; C. C. 1870, 168).

Preparation.—The aqueous extract of opium is pptd. by Na_2CO_3 , the pp. dissolved in ether, the ethereal solution shaken with dilute HOAc , and the acid solution poured into aqueous NaOH . After 24 hours the ppd. thebaine and papaverine are filtered off, the filtrate neutralised with HCl , pptd. by NH_3 , and shaken with chloroform. The chloroform takes up codeine, lanthopine, and meconidine, and is then shaken with dilute HOAc , and the solution exactly neutralised by NaOH , when lanthopine is pptd.

Properties.—White powder composed of minute prisms (from CHCl_3). Insol. water, nearly insol. alcohol, v. sl. sol. ether and benzene, m. sol. chloroform. When pptd. from solutions by KOH or lime it dissolves in excess of the precipitant. NH_3 gives a pp. insol. excess. It does not give a blue colour with FeCl_3 . Conc. HNO_3 gives an orange-red colour. H_2SO_4 gives no colour in the cold, but a brownish-yellow colour at 150°.

Salts.—The sulphate forms extremely thin needles. B^+HClO_4 extremely thin needles, appearing like a jelly when in mass; v. sol. boiling water. $\text{B}^+\text{H}_2\text{PtCl}_6$ 2aq: lemon-yellow crystalline powder; insol. water, alcohol, and HClAq .

LANUGINIC ACID. C 41.6 p.c., H 7.3 p.c., N 16.3 p.c., S 3.4 p.c., O 31.4 p.c. An acid produced by the action of boiling baryta-water upon wool (Champion, C. R. 72, 330; Knecht & Appleyard, B. 22, 1120). The excess of baryta is removed by CO_2 , the acid pptd. by lead acetate, and the pp. decomposed by H_2S . Yellowish porous mass, v. sol. hot water, sl. sol. alcohol, insol. ether. Its aqueous solution ppts. colouring matters as lakes. It also ppts. tannin and most metallic oxides from their acetates. It reacts like a proteid with Millon's reagent and with phosphotungstic acid.

LAPACHIC ACID $\text{C}_{15}\text{H}_{11}\text{O}_5$, i.e. $\text{C}_{15}\text{H}_9\text{O}_5(\text{OH})(\text{OH})\text{CH}_2\text{CH}_2$. *Oxy-aminyl-naphthoquinone. Taiguic acid.* [138°].

Occurrence.—A yellow colouring matter present in the 'lapacho' wood of a genus of the Bignoniacae, several species of which are indigenous to the Argentine Republic and other parts of South America (Siewert, Report of Argentine Republic, cap. 15, Philadelphia). Oc-

curs also in Greenheart from Surinam (Stein, J. pr. 99, 8), and in Bethabarra wood (Greene & Hooker, Ann. 11, 267).

Preparation.—The wood (10 kilos.), in the form of saw-dust, is boiled with a moderately-concentrated solution of sodium carbonate (500 grms. crystallised salt in 80 litres water) the extraction is repeated several times. The solution is of a blood-red colour, and the addition of hydrochloric acid precipitates the crude acid together with a red-brown resin, from which it is best purified by frequent solution and recrystallisations from benzene (Paternò, G. 9, 505, 12, 337; Arnaudon, C. R. 46, 1152). Yield 5 p.c. of pure material.

Properties.—Monoclinic prisms; $a:b:c = .7206:1: .6492$; $n = 97.9$ (Pantebianco, G. 10, 80); v. sol. boiling alcohol, benzene, and ether. It dissolves readily in solutions of the alkalis and alkaline earths, forming red solutions containing salts of the acid. It decomposes carbonates on boiling.

Reactions.—1. Completely oxidised by chromic acid. —2. Alkaline KMnO_4 gives oxalic acid. —3. Boiling nitric acid (S.G. 1.38) yields phthalic acid. —4. Distillation with zinc-dust yields isobutylene, naphthalene, and possibly a homologue of naphthalene. —5. Boiling with HIAq and phosphorus forms amyl-naphthalene (305°) and a little di-(β)-naphthyl, both being perhaps derived from an intermediate naphthyl-amylenes. 6. Cold conc. HNO_3 (S.G. 1.49) or H_2SO_4 gives lapachone. —7. Zinc-dust and potash reduce it to an unstable crystalline hydride, re-oxidised by air to lapachic acid.

Salts.— NaA 5aq: scarlet radio-crystalline mass. S. (of NaA) 15.1 at 24°. Sol. alcohol. — KA . S. 33.3 at 24°. — NH_4A aq: large brick-red crystals. — CaA_2 aq: amorphous red pp. S. 224 at 24°. — BaA_2 7aq: long slender needles (from boiling water). S. 23 at 26°. — SrA_2 aq: — PbA_2 : amorphous red pp.; insol. water. — AgA : scarlet powder. —Aniline salt $\text{C}_6\text{H}_5\text{NH}_3\text{A}$: [122°]; orange prisms (from alcohol). —*o*-Toluidine salt $\text{C}_6\text{H}_4\text{MeNH}_3\text{A}$: [135°]; yellow laminæ. —*p*-Toluidine salt: [130°]; orange-yellow laminæ.

Acetyl derivative $\text{C}_{15}\text{H}_{11}\text{AcO}_5$. [89°]. Formed, together with a compound $\text{C}_{15}\text{H}_{11}\text{O}_5$ (?), by heating lapachic acid with NaOAc and Ac_2O (Paternò). Sulphur-yellow prisms; insol. water, sol. alcohol, ether, and benzene. Readily converted by potash into lapachic acid. Br in HOAc converts it into bromo-lapachone. HNO_3 (S.G. 1.48) at 0° forms a nitro-compound $\text{C}_{15}\text{H}_{11}(\text{NO}_2)\text{AcO}_5$ [170°]; crystallising in reddish plates. The compound $\text{C}_{15}\text{H}_{11}\text{O}_5$ forms small white acicular prisms [132°]; v. sl. sol. cold alcohol and ether. Boiling alcoholic KOH does not saponify it, but converts it into a compound $\text{C}_{26}\text{H}_{28}\text{O}_6$, which crystallises (from alcohol) in orange needles [141°]. Br does not convert the compound $\text{C}_{15}\text{H}_{11}\text{O}_5$ into bromo-lapachone.

Bromo-lapachone $\text{C}_{15}\text{H}_{11}\text{BrO}_5$, i.e.

$\text{C}_{15}\text{H}_9\text{O}_5 \begin{smallmatrix} \text{CHBr} \\ \text{CHBr} \end{smallmatrix} \text{CHPr} (?)$. [145°]. Formed by

warming lapachic acid with Br in HOAc (Paternò, G. 12, 353). Orange laminæ; v. sol. hot alcohol, sol. HOAc , and benzene, sl. sol. ether, insol. cold aqueous alkalis. HNO_3 oxidises it to phthalic acid.

Lapachone $C_{11}H_{10}O_2$, &c.

$C_{11}H_{10}O_2 < \begin{smallmatrix} OH \\ O \end{smallmatrix} > CHPr(?)$. [156°]. Formed by the action of H_2SO_4 or cold conc. HNO_3 (S.G. 1.49) on lapachic acid (Paternò, *G.* 12, 887; Hoeker & Greene, *B.* 22, 1723). Silky orange-red needles (from alcohol); insol. water, v. sol. hot alcohol and benzene. HNO_3 oxidises it to phthalic acid. Distillation over red-hot zinc dust gives naphthalene and isobutylene. Ac_2O has no action. Boiling with $NaOAc$ and Ac_2O forms a compound $C_{10}H_{12}O_4$, crystallising in brown tables with blue reflex; nearly insol. Ac_2O . $NaHSO_4$ forms a white crystalline compound. Combines readily with hydroxylamine and with NH_3 . Its molecular weight, found by Raoult's method, agrees with the formula $C_{11}H_{10}O_2$. Lapachone is converted by heating with alkalis into $C_{11}H_{10}O_2(OH).CH_2CH(OH)Pr$, which separates from cold alcohol or $HOAc$ in large crystals [125°]; v. sol. most solvents; readily converted into lapachone by dilute HCl , and forming the salts $BaA''aq$ and $Ag_2A''aq$, both crystallising in red needles.

LARCH FUNGUS. This fungus extracted with 95 p.c. alcohol yields a mixture of at least four different resins (Masing, *Ar. Ph.* [3] 6, 111).

(a) $C_{41}H_{72}O_8$. [125°]. S. (95 p.c. alcohol) 3 at 142°. Insol. chloroform.

(b) $C_{46}H_{80}O$. [90°]. S. (95 p.c. alcohol) 7. Sol. chloroform.

(c) $C_{10}H_{16}O_8$. Agaricic acid. [272°]. Needles; v. sl. sol. boiling alcohol, insol. chloroform (Jahns, *Ar. Ph.* 221, 269).

(d) A portion easily soluble in alcohol, and partly ppd. by water, leaving in solution a resin (O 61.9 p.c.; H 8.1 p.c.; O 30.0 p.c.) S. 17; S. (alcohol) 1.7. The resinous mixture is altered by boiling with milk of lime, the pp. then thrown down by HCl being separated by chloroform into two substances: $C_{20}H_{32}O_8$, insol. chloroform, S. (alcohol) 6, and $C_{33}H_{52}O_8$, sol. chloroform, S. (alcohol) 2.1.

LARDACEIN v. PROTEIDS.

LARD OIL. A nearly colourless fatty oil, obtained by pressing hog's lard. S.G. 20° 9122; n_D 1.4686 (Long, *Am.* 10, 892).

LARICIC ACID $C_{18}H_{26}O_2$. [153°]. S. 1.14 at 60°. Obtained from the small branches of larch trees (*Pinus larix*) from 20 to 30 years old (Stenhouse, *Pr.* 11, 406). The bark is exhausted with water at 80°, and the extract evaporated and distilled. The distillate is evaporated at 80° and the resulting crystals purified by sublimation. Long monoclinic crystals resembling benzoic acid, usually in twins. Sublimes at 93°. Volatile with steam. Has a bitter astringent taste and powerful odour. Reddens litmus slightly. M. sol. boiling water and alcohol, insol. ether. Nitric acid oxidises it to oxalic acid. Its aqueous solution is ppd. by baryta-water, but not by lead or silver salts. Ferric chloride gives a purple-red colour. The K salt forms flat reddish-brown crystals, decomposed by CO_2 .

LARREA RESIN. Occurs on branches of *Larrea mexicana* (Stillmann, *B.* 13, 756). 61.7 p.c. of it dissolves in alcohol, 26.3 in aqueous potash, and 1.4 p.c. consists of a colouring matter soluble in water.

LASERPITIN $C_{11}H_{12}O_2$ (Feldmann, *M.* 135, 186; *Bl.* 1866, i. 457) or $C_{11}H_{12}O_2$ (Küllz, *Ar. Ph.*

[8] 21, 161). [114°] (F.); [118°] (K.). A bitter principle contained in the root of *Laserpitium latifolium*. Extracted by 80 p.c. alcohol (F.) or by light petroleum (K.). Prisms. Insol. water, sol. benzene, chloroform, ether, and CS_2 . May be sublimed. Its alcoholic solution is ppd. by water, but not by alcoholic lead acetate (F.). Insol. dilute acids and alkalis. Conc. H_2SO_4 and conc. $HClAq$ form deep-red solutions (K.). When heated with conc. alcoholic KOH it is resolved into angelic acid and laserin $C_{11}H_{12}O_4$ (F.) or $C_{10}H_{10}O_4$ (K.), a crystalline resin, insol. acids, sol. ether, alcohol, chloroform, and $HOAc$. Potash-fusion gives methyl-crotonic acid and laserin (K.).

Laserpitin forms an acetate $C_{11}H_{12}O_2.HOAc$ crystallising from acetic acid in silky needles (K.).

Acetyl derivative $C_{11}H_{12}O_2.AcO$. [113°]. From laserpitin, Ac_2O , and dry $NaOAc$ (F.). Colourless needles, insol. water, sol. $HOAc$, alcohol, ether, and $CHCl_3$.

Bromo-derivative $C_{10}H_{10}BrO_4$. [90°]. Formed by the action of Br on a solution of laserpitin in $CHCl_3$ (K.). Needles, sol. alcohol, ether, $CHCl_3$, and $HOAc$.

Di-nitro-derivative $C_{11}H_{12}(NO_2)_2O_4$, aq. [115°]. From laserpitin and HNO_3 (K.). Amorphous mass, insol. water, sol. alcohol, ether, $CHCl_3$, and $HOAc$.

LAUDANINE $C_{20}H_{29}NO_3$ (Hesse, *A.* 153, 57; 176, 201; *Suppl.* 8, 272). [165°]. S.G. 1.256 (Schröder, *B.* 13, 1075). S. (ether) 165 at 18°. $[a]_D = -13.5$ in a 2 p.c. chloroform solution at 22.5°.

Preparation.—An aqueous extract of opium is ppd. by lime or Na_2CO_3 ; the filtrate is shaken with ether; the ethereal solution is shaken with dilute acetic acid; the acetic acid solution is neutralised exactly with NH_3 ; the ppd. lanthopine is removed by filtration; the filtrate is ppd. by excess of ammonia, and the pp. crystallised from ether. Laudanine separates first from the ethereal solution, and afterwards codamine. The laudanine is dissolved in acetic acid solution, and the solution mixed with excess of $NaOH$, which ppt. cryptopine. The alkaline filtrate is ppd. by ammonium chloride, and the pp. dissolved in aqueous $HOAc$; on adding KI laudanine hydro-iodide is ppd., and this is decomposed by ammonia and the free base crystallised from ammonia.

• **Properties.**—Stellate groups of small six-sided prisms (from alcohol). Cannot be sublimed. Tasteless. Levorotatory. In the crystalline state it is v. sol. benzene, $CHCl_3$, and boiling alcohol, sl. sol. cold alcohol, v. sl. sol. ether. In the amorphous state it is much more soluble. Its salts have a bitter taste. From their solutions caustic potash and ammonia ppt. the base in white amorphous flocks, which soon become crystalline, and dissolve in excess of the precipitant. Chloroform extracts the base from the ammoniacal but not from the potash solution. Conc. H_2SO_4 (containing ferric salt) gives an intense rose-red solution, which at 150° changes to dark violet. Conc. HNO_3 gives an orange-red solution. $FeCl_3$ gives an emerald-green colour. The base is poisonous, its hydrochloride acting physiologically like strychnine.

Salts.— $B_2.H_2SO_4$, 4 aq; concentric groups of

needles; v. s. sol. water, almost insol. dilute H_2SO_4 .—B'HCl 6aq: prisms; v. sol. water and alcohol, v. sl. sol. NaCl aq. Inactive to light.—B'HBz 2aq: nodules. S. 3-5 at 20°.—B'HI aq: crystalline powder. S. 2 at 15°, v. sol. boiling water, insol. KIAq.—B' H_2PtCl_6 2aq: yellow amorphous pp., v. sol. boiling water.—B' $H_2C_2O_4$ 6aq: concentric groups of delicate needles. [110°]. S. 2-2 at 10°.—B' $C_4H_4O_3$ 3aq: [100°]. S. 4-9 at 15°.

LAUDANOSINE $C_{21}H_{33}NO_4$. [89°]. S. (ether) 5-2 at 16°. $[a]_D^{25} = 105$ in a 2 p.c. alcoholic solution at 22-5°; $n_D^{25} = 56$ in a 2 p.c. chloroform solution at 22-5°.

Preparation.—Obtained from opium by ppg. the aqueous extract with Na_2CO_3 , dissolving the pp. in ether, shaking the ethereal solution with dilute HOAc, and pouring the acid solution into aqueous NaOH. The pp. contains a large number of bases, and is warmed with alcohol and dilute HOAc, and partially evaporated at 50°. Papaverine and narcotine are then ppd., and thebaine and tartrate is ppd. by adding tartaric acid to the filtrate. The filtrate is exactly neutralised with NH_3 , and $NaHCO_3$ added. After a week the pp. is collected and extracted with benzene. Cryptopine and protopine separate first from the benzene, and when the filtrate is shaken with $NaHCO_3$, laudanose separates (Hesse, A. Suppl. 8, 321). It is purified by dissolving in acetic acid; ppg. with KI; decomposing the resulting salt with NH_3 ; and recrystallising from benzene.

Properties.—Needles. More soluble in ether than thebaine and cryptopine, extremely sol. alcohol and chloroform, v. sol. boiling benzene and ligroin, insol. water and alkalis. Conc. H_2SO_4 (containing ferric salt) gives a brownish-red solution, which at 150° becomes green, and finally dark greenish-violet. $FeCl_3$ gives no colour. Tastes slightly bitter; its salts have an extremely bitter taste. Its alcoholic solution exhibits a strong alkaline reaction. Dextrorotatory. Its hydrochloride is also dextrorotatory, $[a]_D^{25} = 108$ in a 2 p.c. solution at 22-5°.

Salts.—B'HI aq: small prisms; v. sl. sol. cold water, v. sol. alcohol.—B' H_2PtCl_6 3aq: yellow amorphous pp., insol. cold water.—B' $H_2C_2O_4$ 3aq: prisms, v. o. sol. water.

LAUREL OILS. The essential oil from the leaves of the common cherry-laurel (*Cerasus laurocerasus*) consists of benzoic aldehyde, HCy, a volatile oil (possibly benzyl alcohol) convertible by oxidation into benzoic acid, and minute quantities of an odorless resin (Tilden, Ph. [3] 5, 761; cf. Leger, Ph. [3] 3, 971). The essential oil from the fruits of *Laurus nobilis* contains a levorotatory terpene $C_{15}H_{26}$ (164°) S.G. 15° 0.908, a levorotatory sesquiterpene $C_{15}H_{24}$ (250°) S.G. 15° 0.925, and lauric acid $C_{12}H_{24}O_2$ (Blas, A. 134, 1; Gladstone, C. J. 17, 1). The essential oil from the leaves of the Californian laurel (*Oreodaphne californica*) contains terpineol (168°) and umbellol $C_{12}H_{18}O$ (216°) (Stilbmann, B. 13, 629).

Laurel-nut oil is a fatty oil, S.G. 0.932, derived from *Calophyllum inophyllum* growing in the East (Hooper, Ph. [3] 19, 522).

LAURENE v. DI-METHYL-ETHYL-BENZENE.

LAURIC ACID $C_{12}H_{24}O_2$. *Dodecoic acid*. Mol. w. 200. [48-6°] (Heints). (225°) at 100 mm.

(Krafft, B. 13, 1415). S.G. 25° 0.883 (Görgey). H. C. 1759720 (Lougouine, A. Ch. [6] 11, 223). Occurs as glyceryl ether in the berries of the bay tree (*Laurus nobilis*) (Marsson, A. Ch. 41, 33; Blas, A. 134, 1), in the fat of picurim beans (Sthamer, A. 53, 393), in the volatile oil of these beans (Müller, J. pr. 58, 469), in small quantity in spermaceti (Heintz, A. 92, 394), in croton oil (Schlippe, A. 105, 14), in the fruit of *Cylocodaphne sebifera* (Gorkom, Tydschrift af neerl. Indie, 81, 410), in the so-called Dika bread, the fruit of *Mangifera gabonensis* (Oudemans, J. pr. 81, 356), in the age of the Mexicans, a fat obtained from *Coccus Axia* (Hoppe, J. pr. 80, 102), and in cocoa-nut oil (Görgey, A. 66, 303).

According to Schering (A. 96, 236) it is among the products of the distillation of cetyl alcohol with potash-lime, but Heintz (A. 97, 271) denies this. A dodecoic acid [35°], isomeric with lauric acid, may be obtained by treating the amide of myristic acid with Br and NaOH, and converting the resulting dodecylamine into the nitrile and thence into the amide [97°] of dodecoic acid, and boiling the amide with conc. HCl aq (Lutz, B. 19, 1433).

Preparation.—Lauric acid may be obtained from fats containing it by saponification followed by fractional precipitation of the acids by barium acetate (Heintz, A. 92, 294; J. pr. 429, 583; J. pr. 66, 1). It may also be obtained from the fat of bay-berries by saponifying, distilling the solid fatty acids under reduced pressure, and rectifying in vacuo (Krafft, B. 12, 1665).

Properties.—Silky needles united in tufts (from alcohol) or seamy crystalline mass (after fusion). Its alcoholic solution has a slight acid reaction. It is slightly volatile with steam. Insol. water, v. sol. alcohol and ether. Gives di-enyl ketone $(C_{11}H_{23})_2CO$ when its calcium salt is distilled.

Salts.—KA'. Amorphous. S. (alcohol) 4-5 at 15°; 38 at 78° (Oudemans, C. C. 1863, 737).—KHA'. Crystalline. S. (alcohol) 1-5 at 15°; 400 at 78°.—NaA'. White powder. S. (alcohol) 2-5 at 15°; 14-5 at 78°.—NaHA'. S. (alcohol) 2 at 15°.—NH₄A'. S. (alcohol) 6 at 15°.—BaA'. Crystalline spangles (from alcohol). S. 0.07 at 100°; 0.054 at 15° (Oudemans); 0.09 at 17°; 50 at 100° (Görgey). S. (alcohol) 0.187 at 15°; 1.009 at 78° (O.); 0.7 at the cold; 0.5 at 78° (G.).—CaA'. aq: S. 0.0039 at 15°; 0.547 at 100°. S. (alcohol) 0.0719 at 15°; 2.20 at 78° (O.).—SrA'. aq: S. 0.0272 at 15°; 0.36 at 100°. S. (alcohol) 0.06 at 15°; 0.36 at 78°.—MgA'. aq: S. 0.023 at 15°.—PbA'. [110°-120°] (Heintz). S. 0.0011 at 100°. S. (alcohol) 0.0047 at 15°; 0.235 at 100°.—CoA'. aq.—NiA'. aq.—NiA'. 3aq.—CuA'. S. 0.0023 at 15°; 0.029 at 100°.—AgA'. white powder, consisting of minute slender needles. S. 0.001 at 15°; 0.405 at 100°. S. (alcohol) 0.0323 at 15°; 0.324 at 78°.

Ethyl ether EtA'. [-10°]. (269°) at 760 mm. (Delfs, A. 92, 278). S.G. 25° 0.86 (Görgey). V.D. 8.4. (calc. 7.9). From the acid, alcohol, and HCl.

Glyceryl ether $C_3H_5(C_{12}H_{23}O_2)_3$ (Schiff, B. 7, 781). *Trilaurin*. *Laurostearin*. [45°]. H. C. 5707420° (Lougouine, A. Ch. [6] 11, 222). Obtained from bay berries by extracting with alco-

hol. Silky needles; al. sol. cold alcohol, v. sol. ether.

Phenyl ether $\text{C}_6\text{H}_5\text{O} \cdot \text{C}_{12}\text{H}_{25}$: $[24\frac{1}{2}^\circ]$; $(210^\circ \text{ at } 15 \text{ mm})$; pearly plates.

p-Tolyl ether $\text{C}_6\text{H}_4(\text{CH}_3)\text{O} \cdot \text{C}_{12}\text{H}_{25}$: $[28^\circ]$; $(220^\circ \text{ at } 15 \text{ mm})$ (Krafft a. Bürger, B. 17, 1378).

Amide $\text{C}_{11}\text{H}_{23}\text{NO} \cdot \text{NH}_2$: $[102^\circ]$ (Krafft a. Stauffer, B. 15, 1729). From the chloride and NH_3 .

Chloride $\text{C}_{11}\text{H}_{23}\text{CO} \cdot \text{Cl}$. $[-17^\circ]$. $(142\frac{1}{2}^\circ \text{ at } 15 \text{ mm})$. Colourless liquid (Krafft, B. 17, 1378).

Nitrile $\text{C}_{11}\text{H}_{21}\text{CN}$. $[4^\circ]$. $(198^\circ \text{ at } 100 \text{ mm})$. S.G. $\frac{4}{4} = .835$; $\frac{15}{15} = .827$; $\frac{100}{100} = .767$. Formed by distilling lauramide with P_2O_5 (Krafft a. Stauffer, B. 15, 1729). Colourless liquid of peculiar odour.

LAURIC ALDEHYDE $\text{C}_{11}\text{H}_{23}\text{CHO}$. $[45^\circ]$. $(143^\circ \text{ at } 22 \text{ mm})$. Prepared by the dry distillation of a mixture of calcium laurate and formate (Krafft, B. 13, 1414). White crystalline odourless solid.

LAURIN $\text{C}_{22}\text{H}_{44}\text{O}_4$. *Bay-berry camphor*. A substance discovered by Bonastre (J. Ph. 10, 32) in the berries of the bay-tree, and further examined by Marsson (A. 41, 329) and Delffs (A. 88, 854). It is prepared by boiling the skinned and pounded berries with alcohol of 85 to 90 p.c., filtering at the boiling heat, and leaving the liquid to itself for several days. Lauric acid is then first deposited; and on filtering again and leaving the liquid to evaporate, laurin is deposited in crystals contaminated with a viscid oil, from which they may be freed by pressure between paper and recrystallisation. Dimetric crystals, destitute of taste and smell, insol. water, v. sol. alcohol, even in the cold, sol. ether. The solutions are neutral to test-papers. Laurin does not dissolve in alkalis. Laurin cannot be distilled without decomposition. Its alcoholic solution is not precipitated by acetate of lead or nitrate of silver.

LAUROCERASIN. A name given by Lehmann (N. R. P. 23, 440) to amygdalin when extracted from the leaves of the cherry laurel (*Cerasus laurocerasus*) or the bark of the berry-bearing alder (*Rhamnus Frangula*), v. AMYGDALIN.

LAURONE $\text{C}_{23}\text{H}_{46}\text{O}$ i.e. $(\text{C}_{11}\text{H}_{23})_2\text{CO}$. *Dimethyl ketone*. $[69^\circ]$. S.G. $\frac{70}{70} = .802$; $\frac{100}{100} = .788$. Formed by distilling barium laurate with lime. Shining plates (from alcohol). On reduction it gives tricosane (Overbeck, P. 86, 591; A. 84, 259; Krafft, B. 15, 1712).

LAURONIC ACID $\text{C}_{11}\text{H}_{21}\text{O}_2$ i.e. $\text{C}_6\text{H}_5\text{CO}_2\text{H}$. Formed by distilling camphoric acid, or by heating its barium salt with water at 200° ; campholactone is formed at the same time (Woringer, A. 227, 7).

Properties.—Oil. Sol. water and ether. Volatile with steam. In presence of HCl some of it changes into the isomeric campholactone. When distilled with water, a great part changes to the campholactone.

Salts.— CaA , BaA . Forms dendritic crystals on the surface of an evaporating solution.— AgA .

LAUROSTEARIN v. *Glyceryl ether of LAURIC ACID*.

LAUROXYLIC ACID v. *DI-METHYL-BENZOID ACID*.

LAUTH'S VIOLET v. AMIDO-IMIDO-IMIDO-IMIDO-PHENYL SULPHIDE.

LAVEREND OIL. A volatile oil obtained by distilling the flowers of *Lavendula officinalis* with steam. S.G. 15-875. It contains a levorotatory terpene $\text{C}_{10}\text{H}_{18}$ (162°) which forms a crystalline hydrochloride and various oxygenated bodies which yield camphor on further oxidation (Dumas, A. Ch. 13, 275; Lallemant, A. 114, 198; Barth, Z. 1867, 509; Bruylants, J. Ph. [4] 30, 39). English oil of lavender submitted to fractional distillation yields 30 p.c. of the terpene (176° - 186°), and 30 p.c. of oxygenated products (200° - 207°) (Shenstone, Ph. [2] 13, 207).

LEAD. Pb. At.w. 206.4. Mol. w. not known with certainty, but probably same as at. w. (v. p. 124). $[330^\circ$ - $335^\circ]$ (Brigel, B. 6, 191; Pictet, P. M. [5] 7, 446); $[326^\circ]$ (Riemsdyk, C. N. 20, 32; Person, J. 1849). (Between 1450° and 1600°) (Carnelley a. Williams, C. J. 85, 565). S.G. 11-335 at 0° (Quinke, P. 97, 856); 11-37 at 0° (Reich, J. pr. 78, 328); 11-345 to 11-368 at 4° , 11-352 to 11-366 at 23° (Schwepitzer, Am. Ch. 7, 174). S.G. molten 10-37-10-65 (Roberts a. Wrightson, A. Ch. [5] 30, 181). For other values for S.G. v. Clarke's Table of Spec. Gravities [1888], pp. 5-6. S.H. -73° to 11° -03065 (Regnault, A. Ch. [3] 26, 286); S.H. 19° to 48° -0315 (Kopp, Tr. 1865, 71); S.H. molten 340° to 450° -0402 (Person, A. Ch. [3] 24, 129). C.E. 0° to 100° -00002799 (Matthiessen, Pr. 15, 220). T.C. (Ag = 100) 8.5 (Wiedemann a. Franz, P. M. [4] 7, 33). Heat of fusion 5858 (Rudberg, P. 19, 125); 5369 (Person, A. Ch. [3] 24, 129). E.C. (Hg at $0^\circ = 1$) 4.8 at 0° , 3.363 at 100° (Lorenz, W. 13, 422, 582). Crystallises in regular octahedra. For emission-spectrum of lead v. Werther, J. pr. 88, 180; Cornu, C. R. 73, 332; L. de Boisbaudran, C. R. 77, 1152; Hartley a. Adeney, Tr. 1884, 63.

Occurrence.—Lead occurs native in small quantities (e.g. v. Chapman, P. M. [4] 81, 176; Koksharov, J. M. 1875, 873; Igelström, J. M. 1889 (il.) 32). *Galena* (PbS) is very widely distributed; the other most important ores of lead are *cerussite* (carbonate), *anglesite* (sulphate), *pyromorphite* (phosphate), and *minersite* (arsenate). Small quantities of oxychloride, chromate, molybdate, tungstate, vanadate, &c., of Pb also occur. Lead has been known and used from very early times.

Formation.—1. PbS is roasted in a reverberatory furnace until a portion is oxidised partly to PbO and partly to PbSO_4 ; the doors are then closed, and the PbS , PbO , and PbSO_4 react to produce SO_2 and Pb ; $\text{PbS} + 2\text{PbO} = 3\text{Pb} + \text{SO}_2$; $\text{PbS} + \text{PbSO}_4 = 2\text{Pb} + 2\text{SO}_2$.—2. PbS is roasted in a reverberatory furnace, the temperature being gradually increased until a considerable quantity of PbSO_4 and a little PbO are produced; the doors are then closed, and the temperature is raised until the mass softens but does not melt. When the PbS and PbSO_4 react to produce Pb and SO_2 , the residue is again roasted, whereby more PbSO_4 is formed, and on raising the temperature with closed doors the PbSO_4 and PbS react as before. After a time the quantity of PbSO_4 relatively to PbS becomes so great that the chief product of their reaction is PbO ($\text{PbS} + 3\text{PbSO}_4 = 4\text{PbO} + 4\text{SO}_2$); coal and wood are then thrown into the furnace, and heating is

continued, when the PbO is reduced to $Pb(PbO + C = Pb + CO)$; at the same time some of the $PbSO_4$ is partly reduced to PbS , which, reacting with the remaining $PbSO_4$, produces Pb and SO_2 ($2PbSO_4 + 2C = PbSO_4 + PbS + 2CO_2$).—3. PbS is melted with scrap Fe ; $PbS + Fe = FeS + Pb$.—4. $PbCO_3$ is strongly heated with C ; $PbCO_3 + 2C = Pb + 3CO$.—5. PbO is reduced by heating in H or CO , or with C , KCN , or Na .—6. Zinc is suspended in an acidulated solution of a Pb salt, when Pb is pptd. on the zinc.—7. $PbCl_2$ is mixed with Na_2CO_3 , and heated with KCN or C .

Preparation.—1. By melting Pb prepared by one of the foregoing methods, exposing the molten mass to a gentle current of air, blowing water-vapour through the mass, and running off the metal from beneath the film of oxides of Cu , Sb , Fe , &c., nearly pure Pb is obtained.—2. Pb oxalate is strongly heated in a carbon crucible, or is mixed with powdered C and heated.—3. Stas prepared pure lead by the following process (*Chem. Propert.* 324). Commercial Pb acetate was dissolved in water, and digested at 40° to 50° in a leaden vessel with sheets of Pb until all Cu and Ag were pptd.; the filtered liquid was run into almost boiling water, strongly acidulated with H_2SO_4 ; the pptd. $PbSO_4$ was very thoroughly washed, and then suspended in a solution of NH_4 sesquicarbonate and NH_3 , until transformed into $PbCO_3$; the $PbCO_3$ was thoroughly washed, a part of it was decomposed to PbO by heating in a Pt dish, and the rest was almost, but not quite, entirely dissolved in dilute HNO_3 Aq; the solution of $Pb(NO_3)_2$ was heated to boiling, and the PbO was added little by little; the last traces of Fe were thus pptd. as oxide; the boiling liquid was filtered and poured into solution of NH_4 sesquicarbonate. In this way pure $PbCO_3$ was obtained. The $PbCO_3$ was dried, and added little by little to pure molten KCN contained in an unglazed porcelain crucible placed within a larger crucible, the space between being filled with powdered Al_2O_3 , previously heated and mixed with 5 p.c. melted and powdered borax. The Pb thus obtained was again placed in pure molten KCN , and kept there until the upper surface of the Pb appeared convex and lustrous like pure Hg ; after partial cooling the Pb was run off into a mould of polished steel. If a trace of PbO or PbS is present in the molten Pb the surface does not become convex.

Properties.—Almost white, lustrous metal. Ordinary lead is blue-gray; it contains traces of Ag , Cu , Sb , and sometimes Fe and Mn . Very malleable and ductile, but the properties are greatly affected by small quantities of impurities, notably by PbO , which is somewhat soluble in molten Pb . Tenacity very low. Somewhat sonorous. Leaves a mark on paper. Lead is so soft that it can be cut by a knife or scratched by the nail; traces of foreign metals, or of As or S , increase the hardness of Pb . By slowly cooling molten Pb , piercing a hole in the crust by an iron rod, and pouring off the still molten portion, the metal is obtained in regular octahedra often aggregated together similarly to crystals of NH_4Cl (Marx, *S.* 57, 193; Stolba, *D. P. J.* 164, 373). Crystals of Pb are also obtained by hanging a rod of zinc in a slightly acidulated solution of a Pb salt, or by passing an electric current through

such a solution. Pb vaporises at high temperatures (1400° – 1600°); the vapour is very poisonous. The lustrous surface of Pb quickly tarnishes in ordinary air from formation of a film of oxide (probably PbO). Very finely divided Pb is quickly changed to the suboxide Pb_2O ; such finely divided Pb may be obtained by covering a Zn plate with a little $PbSO_4$, made into a paste with water, laying another Zn plate on the top, and placing the whole in $NaCl$ Aq for 9 or 10 days (*v. Bolley, Ph. C.* 1850. 59). Pb is readily changed to PbO on the surface by melting in air. Pb is not changed in dry air, nor when kept under pure water from which all air has been removed; in contact with water and the atmosphere it becomes gradually covered with a white deposit of $2PbCO_3$, $PbO.H_2O$, and small quantities of a soluble Pb salt are also formed (*v. Reactions*, No. 2). Pb is soluble in HNO_3 Aq, and is slowly changed to $PbCl_2$ by the action of HCl Aq in the air; hot conc. H_2SO_4 forms $PbSO_4$; Pb is oxidised by heating with KNO_3 or $KHSO_4$. Combines with the halogens, also with S , Se , P , and As ; forms alloys with many metals.

The atomic weight of Pb has been determined (1) by finding V.D. of $PbCl_2$ (Roscoe, *Pr.* 27, 420), and analyses of this compound (Marignac, *Ar. Sc.* 1, 59, 209; Dumas, *A. Ch.* [8] 55, 196); (2) by syntheses of $Pb(NO_3)_2$ and $PbSO_4$ (Stas, *Rech.* 101; *Chem. Propert.* 329); (3) by converting Pb , PbO , and PbS into $PbSO_4$, and by analysing $PbCO_3$ (Berzelius, *P.* 8, 15; *G. A.* 37, 259, 265; Turner, *A.* 13, 17); (4) by determining S.H. of Pb (Regnault, *A. Ch.* [3] 26, 286).

Lead is metallic in its chemical behaviour. The oxide PbO is strongly basic; it is slightly soluble in water, and the solution turns red litmus blue and absorbs CO_2 from the air; it decomposes hot solutions of NH_4 salts with evolution of NH_3 , and it reacts with acids to form salts PbX_2 ($X = NO_3, SO_4$, &c.), $PbCO_3$ is isomorphous with the carbonates of the alkaline earths; on the other hand, PbO dissolves in fairly conc. KOH Aq, probably forming a salt $PbO.K$, and compounds of PbO with CaO and Ag_2O are known. PbO_2 reacts with strong bases, e.g. KOH , to form unstable salts, e.g. K_2PbO_3 ; on the other hand, treatment of PbO_2 with conc. H_3PO_4 Aq or $H_2C_2O_4$ Aq produces solutions which react as if they contained salts of PbO_2 . The greater number of the lead salts correspond with the oxide PbO ; $Pb(CH_3)_2$, however, is stable as a gas.

Lead is placed in Series II. of Group IV.; the other odd series members of this group are Si , Ge , and Sn . Pb more nearly resembles Sn than any other member of Group IV.; it is more distinctly metallic than the other elements of the group; the other elements of this group form several compounds MX_2 , whereas most of the Pb compounds belong to the form MX_4 . Pb forms many basic and several double salts (*cf. CARBON GROUP OF ELEMENTS*, vol. i. p. 684; also *TIN GROUP OF ELEMENTS*, in vol. iv.). In its physical properties Pb resembles Tl ; one series of Tl salts, however, is similar to those of the alkali metals, and the other series resembles those of the earth metals (*v. EARTH METALS OF THE*, vol. ii. p. 424). The atom of Pb is divalent in the gaseous molecule $PbCl_2$, and tetravalent in the gaseous molecule $Pb(CH_3)_4$.

Ramsay (*C. J.* 55, 521) has determined the lowering of vapour-pressure of Hg produced by dissolving Pb in Hg; the results obtained make it probable that the molecular weight of lead is the same as the atomic weight; this result assumes the accuracy of Van't Hoff's law, that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also regards the molecular weight of liquid Hg as the same as the atomic weight.

Reactions.—1. Unchanged in dry air; superficially oxidised (probably to Pb_2O) in moist air; oxidised to PbO by heating in air or oxygen.—2. Water quite free from air has no action on Pb at ordinary temperatures (Stalman, *D. P. J.* 180, 366; Böttger, *J.* 1866, 232; but v. Müller, *J. pr.* [2] 36, 317). Water and air together dissolve a little Pb, and at the same time a deposit of $2PbCO_3 \cdot Pb(OH)_2$ is formed. Water charged with CO_2 under a pressure of a few atmospheres dissolves considerable quantities of Pb (perhaps in the form of an acid carbonate). The presence of small quantities of nitrates, especially NH_4NO_3 , of soluble alkaline chlorides, and of some other salts, e.g. $(NH_4)_2SO_4$, increases the solvent action of water on Pb; the amount of Pb in solution is greater after a few days' action than after many days' exposure to the air. In these reactions the soluble salt of Pb is probably slowly acted on by the CO_2 of the air with formation and ppn. of insoluble $2PbCO_3 \cdot Pb(OH)_2$. The presence of alkaline carbonates or of a little Ca silicate in water almost wholly stops the solvent action on Pb; probably the insoluble hydrocarbonate is formed as quickly as Pb is dissolved. The action of water on lead has been examined by Graham, Miller a. Hofmann, Noad (*C. J.* 4, 20), Yorke (*P. M.* [3] 5, 82), Dumas (*C. R.* 77, 1054), Berthelot (*C. R.* 77, 1063), Pattison Muir (*C. N.* 25, 294; *J.* 102, 125, 145; 34, 223, 234; 35, 82, 110; *C. J.* 31, 660), Müller (*J. pr.* [2] 36, 317), Carnelley a. Frew (*S. C. I.* 7, 15, 78), and others. Granulated lead slowly decomposes boiling water, evolving H (Stolba, *J. pr.* 94, 113).—3. Lead is dissolved by several acids; slowly by hot conc. $HClAq$ in contact with air; also slowly by conc. H_2SO_4 (Calvert a. Johnson, *C. J.* 16, 66); rapidly by HNO_3Aq . For account of gaseous products of reaction with HNO_3Aq v. Ackworth a. Armstrong, *C. J.* 82, 54.

Technical applications of lead.—Lead is largely used for vessels and apparatus in which different chemical processes are conducted, e.g. for sulphuric acid chambers; water-pipes are usually made of lead. Alloys of lead with tin, form solder and pewter; an alloy with As is used for making shot; an alloy with Sb is used as type-metal, and emery wheels and grinding tools used by lapidaries are made of an alloy of Pb and Sb; alloys of Pb with Sn and Bi have low melting-points. Lead oxide, chromate, acetate, and carbonate are all largely used in manufactures.

Detection and Estimation.— $HClAq$ ppt. white $PbCl_2$ from solutions of Pb salts; sl. sol. cold water, fairly sol. hot water, nearly insol. dilute $HClAq$. Dilute H_2SO_4 , or a soluble sulphate, ppt. white $PbSO_4$, almost insol. dilute H_2SO_4Aq , quite insol. alcohol. K_2CrO_4Aq ppts.

yellow $PbCrO_4$, insol. water. $KIAq$ ppts. yellow PbI_2 , sol. boiling water, but reppd. in yellow crystalline spangles on cooling. H_2S ppts. brownish-black PbS , insol. dilute acids, alkalis, or alkaline sulphides; presence of much HCl prevents ppn. from rather dilute solutions of salts of lead; in presence of a little HCl pp. is sometimes red or yellow-red, and consists of $\alpha PbS \cdot \gamma PbCl_2$ (v. Lead, sulphochloride of). The H_2S test is said to detect 1 pt. of lead in 100,000 pts. of water; the H_2SO_4 test 1 pt. in 20,000; and the K_2CrO_4 test 1 pt. in 70,000. Pb may be estimated as $PbSO_4$ by ppn. with dilute H_2SO_4Aq adding about 2 vols. of alcohol, washing with alcohol, drying and calcining.

Supposed allotropic form of lead.

When lead is deposited on the negative electrode by passing a current through a neutral or acid solution of a lead salt, and the current is continued for some hours, the lead becomes the colour of copper (Wöhler, *A. Suppl.* 2, 135). After washing the red leaflets thus obtained with water and alcohol, they retain their colour on exposure to the air, and are not acted on by dilute $HClAq$ or cold dilute HNO_3Aq , or alkalis, but are readily dissolved by hot HNO_3Aq ; heated in H they melt above 200° and become ordinary lead. Wöhler regarded the red substance either as an allotropic form of lead, α as a hydride of lead; Stolba (*J. pr.* 94, 113) suggested that the red colour was due to a film of oxide on the surface of the lead (v. also Schützenberger, *C. R.* 86, 1265).

Lead, alloys of. Lead alloys with many metals; the alloys are produced by fusing together the constituent metals; some of them are definite compounds, in these cases either of the constituents is generally soluble in the compound.

Alloys with bismuth, and with bismuth and other metals. Pb and Bi may be alloyed in all proportions; malleability is diminished by adding more than an equal weight of Bi. By fusing together 70 p.c. Pb, 15 p.c. Bi, and 15 p.c. Sb an alloy is obtained which expands on cooling. An amalgam of Pb (4 pts.) Bi (2 pts.), and Hg (1 pt.) may be melted by rubbing pieces of it together. Alloys of Pb with Bi and Sn are known as fusible alloy; the M.P. varies from c. 90° to c. 170° ; all these alloys are said to solidify at 98° . (For M.P. and solidification-points of these alloys v. Dallo, *C. C.* 1865, 831; for expansion and S.H. v. Spring, *A. Ch.* [5] 7, 178, also Wiedemann, *W.* 3, 237; for thermal conductivity v. Wiedemann a. Franz, *P.* 89, 514; 108, 399; cf. also vol. i. p. 511.)

Britannia metal is composed of equal parts of brass, Sn, Sb, and Bi; *Queen's metal* of 1 pt. Pb, 1 pt. Bi, 1 pt. Sb, and 9 pts. Sn. Alloys of Pb with Bi, Sn, and Ag are very fusible, melting as low as 45° ; the alloy often used for tinning the inside of glass globes, tubes, &c. is made by fusing together 1 pt. Pb, 1 pt. Sn, 2 pts. Bi, and adding 10 pts. Ag.

Alloys with copper v. vol. ii. p. 254.

Alloys with mercury. Pb easily amalgamates with Hg, by rubbing together Pb filings with Hg or by adding Hg to molten Pb. An amalgam containing 83 p.c. Pb is liquid; an amalgam of equal parts Pb and Hg can be crystallised. Contraction occurs during the amalgamation.

Alloy with potassium and sodium. Prepared either by directly heating the metals together or by fusing PbO with an alkaline flux, e.g. with cream of tartar. When distilled with Et₃MeI, &c., compounds of Pb with Et, Me, &c. are obtained.

Alloys with tin. These metals may be alloyed in all proportions; the S.G. of the alloy is always a little less than that calculated from the S.G. of the constituents. There are no indications of the formation of definite compounds (v. Laurie, *C. J.* 55, 677). These alloys are very easily ignited and burnt. The two commonest alloys of Pb and Sn are *solder* and *pewter*. *Fine solder* contains 1 pt. Pb and 2 pts. Sn; *common solder*, equal pts. Pb and Sn; *coarse solder*, 2 pts. Pb and 1 pt. Sn. The M.P. varies from c. 340° for 1 pt. Pb and 2 pts. Sn, to 370° for equal parts Pb and Sn, and 440° for 2 pts. Pb and 1 pt. Sn; by increasing the relative quantity of Pb the M.P. rises until the alloy of 25 pts. Pb to 1 pt. Sn melts at c. 560°; by increasing the relative quantity of Sn, above 2 pts. to 1 of Pb, the M.P. also slightly rises until the alloy of 6 pts. Sn to 1 pt. Pb melts at c. 380°. *Pewter* is an alloy of c. 80 pts. Pb with 20 pts. Sn. According to Rudberg (*P.* 18, 240) when Pb and Sn are melted together and allowed to cool, the thermometer always shows a stationary point at 187°; he thinks that a compound PbSn₂ is always formed, that this alloy has a fixed solidification-point lower than that of Pb (326°) or Sn (228°), and that the heat produced by the solidification of this alloy acting on the excess of Pb or Sn causes fluctuations in the final solidification-point of the whole mixture (v. also Pohl, *W.A.B.* 1850, 402; Riche, *C.R.* 55, 143; Wertheim, *P. Ergänzbd.*, 2, 75; Matthiessen, *P.* 130, 62). It seems that the amount of Pb in pewter vessels for domestic use should not exceed 18 p.c., else Pb may be dissolved out by the action of dilute acids, e.g. vinegar.

Alloys with tin and copper. *Bell-metal* is an alloy of 4.3 p.c. Pb, 80 p.c. Cu, 10.1 p.c. Sn, and 5.6 p.c. Zn. A little Pb is sometimes added to Cu and Sn in making *bronze*.

Alloys with palladium. A crystalline, greyish-white, brittle alloy is obtained by fusing granulated Pb with rather more than its own weight of Pd foil, and removing excess of Pb by the action of acetic acid and CO₂. The alloy has the composition Pd₂Pb; S.G. 11.225 (Bauer, *B.* 3, 691; 4, 449).

Alloys with platinum. An alloy having the composition PtPb is formed by fusing 3 pts. Pb with 1 pt. Pt, and exposing the product to the prolonged action of CO₂, O, and acetic acid vapour (Bauer, *B.* 3, 691; 4, 449). Steel-grey, crystalline; fairly fusible; S.G. 15.736. Bauer (*loc.*) also describes an alloy PtPb₂.

Alloys with zinc. Pb and Zn alloy in all proportions; all the Zn is removed by heating very strongly. Alloying Pb with Zn increases the hardness of the Pb. Alloys of Pb, Zn, and Sn solidify at 168°; when the ratio is 2Pb:Zn:9Sn the alloy solidifies at 168° only, but other alloys show also two higher points.

Lead also alloys with *chromium* and *manganese*.

Lead, antimonate of; v. vol. i. p. 286.

Lead, antimonides of. Pb and Sb may be melted together in all proportions; the alloys are crystalline; most of them are formed with expansion. Ordinary *type metal* consists of 88 pts. Pb and 17 pts. Sb (v. Riche, *C. R.* 55, 143; Matthiessen, *P.* 110, 28; Calvert & Johnson, *P. M.* [4] 18, 354; H. v. d. Planitz, *B.* 7, 1664; Rollmann, *P.* 84, 277).

Lead, arsenates of; v. vol. i. p. 308.

Lead, arsenides of. Pb melted with As takes up c. 16 p.c. of the latter; the alloys are brittle and very fusible; some, but not all, of the As is expelled by heating. *Shot-metal* is an alloy of Pb with not more than 3 p.c. As.

Lead, arsenites of; v. vol. i. p. 306.

Lead, borates of; v. vol. i. p. 530.

Lead, borofluoride of. Pb(BF₃)₂ (= PbF₂.2BF₃). Prismatic crystals; obtained by dissolving PbO in excess of HBF₃Aq and evaporating to a syrup. Crystallises with difficulty; partially decomposed by water or alcohol (Berzelius, *P.* 2, 118; cf. *BOROFUORIDES*, vol. i. p. 526).

Lead, bromide of. PbBr₂. Mol. w. not certain; but from analogy of PbCl₂ is probably 365.9 (= PbBr₂). Melts at c. 499° (Carnelley, *C. J.* 33, 278); boils at c. 861° (Carnelley & Williams, *C. J.* 33, 283). S.G. ppd. PbBr₂ 6.572 at 19.2° (Clarke's *Table of Specific Gravities* [1888] 32). H.F. [PbBr₂] = 64,450; [PbBr₂Aq] = 54,410 (T_h 3, 337). Obtained by digesting PbO or PbCO₃ with HBrAq, or by ppg. the solution of a Pb salt by HBrAq or a soluble bromide. Obtained in well-formed, colourless, rhombic needles by slowly evaporating a solution of Pb in alcohol containing Br (Hjortdahl, *Z. K.* 3, 302). Sl. sol. cold, more sol. hot, water; more sol. acids. From the solution in hot conc. HBrAq (72 p.c. HBr), Ditts says that white lustrous needles, PbBr₂.3H₂O, crystallise (*C. R.* 92, 718); and that the compound 5PbBr₂.2HBr.10H₂O is obtained by passing HBr into the solution of PbBr₂ in HBrAq. After melting, PbBr₂ solidifies to a yellow, horn-like mass. Heated in air, a yellow mass remains containing the *oxybromide* Pb₂OBr₂ (= PbBr₂.PbO); the same oxybromide is obtained by digesting PbBr₂ with Pb(C₂H₃O₂)₂Aq. A compound of PbBr₂ with PbCl₂ has been obtained, also compounds of PbBr₂ with PbI₂ and with Pb(CNS)₂ (v. *Lead, bromochloride of*; *Lead, iodobromides of*; and *Lead, bromosulphocyanides of*). André (*A. Ch.* [6] 3, 104) describes several *double compounds* of PbBr₂ with NH₄Br.

Lead, brom-iodides of; v. *Lead, iodobromides of*.

Lead, bromochloride of. PbBr₂.PbCl₂ (= PbBrCl). White needles, observed by lies in a blast furnace where lead carbonate ores had been reduced (*C. N.* 43, 216); crystallisable from water; S.G. 5.741.

Lead, bromosulphocyanides of.

PbBr₂.Pb(CNS)₂; brownish crystals, by digesting the constituents together, and then crystallising from boiling water. By acidifying with HBrAq, the salt 8PbBr₂.Pb(CNS)₂ is produced (Grissom & Thorp, *Am.* 10, 229).

Lead, chlorides of. Only one chloride of lead, PbCl₂, has been isolated; but there is strong proof of the existence of the tetrachloride, PbCl₄, in solutions of PbO₂ in HClAq.

LEAD CHLORIDE, PbCl₂. (Lead dichloride

Plumbous chloride. Horn-lead. Mol. w. 277.14. S.G. 5.805 at 15° (Stolba, *J. pr.* 97, 503); 5.88 (Brügelmann, *B.* 17, 2359). V.D. 137.1 at c. 1080° (mean of 4) (Roscoe, *Pr.* 27, 426). Melts at 498°, and boils between 861° and 954° (Carnelley, *C. J.* 33, 278; and C. a. Williams, *C. J.* 85, 564). Crystallises in rhombic system; *a:b:c* = 5943:1:5949 (Schabus, *W. A. B.* 1850, 456). H.F. [Pb, Cl²] = 82,770; [Pb, Cl², Aq] = 75,970 (*Th.* 8, 337).

Occurrence.—As *cotunnite*; found in the crater of Vesuvius after the eruption of 1822, mixed with NaCl and CuSO₄.

Formation.—1. By heating Pb in a stream of Cl; combination occurs slowly.—2. By dissolving Pb in hot HClAq in contact with air; PbCl₂ separates on cooling.—3. By adding solution of a chloride, e.g. NaClAq, to a conc. solution of a Pb salt.—4. By dissolving PbS in hot HClAq and crystallising.

Preparation.—PbO or PbCO₃ is boiled with dilute HClAq, and HClAq is added little by little until all is dissolved; the liquid is allowed to cool, and the PbCl₂ which separates is repeatedly crystallised from boiling water.

Properties.—Large, white, rhombic crystals (*v. supra*), which melt at 498° and boil between 861° and 954° (*v. supra*). V.D. at c. 1080° agrees with the formula PbCl₂. Sl. sol. cold water, *S.* = .95 at 16.5°, solution contains .9414 p.c. PbCl₂ (Bell, *C. N.* 16, 69); addition of 1 p.c. HCl diminishes *S.* to .347, and with 14 p.c. HCl, *S.* = .09. If more than 14 p.c. HCl is present *S.* increases; *S.* in HClAq S.G. 1.162 = 2.9 (Bell, *l. c.*). According to Field (*C. J.* [2] 11, 575) PbCl₂ is less soluble in NaClAq containing 5 p.c. NaCl than in water (*S.* = .23); but the values of *S.* for water and conc. NaClAq are about the same. The considerably greater solubility of PbCl₂ in conc. than in dilute HClAq is supposed by Ditte to be due to the formation of a compound of PbCl₂ and HCl which is decomposed by water (*C. R.* 92, 718). Ditte gives the following table:—

HCl in 100 pts. H ₂ O	PbCl ₂ dissolved in 1000 pts. of the liquid in col. 1				
	at 0°	20°	40°	55°	80°
0	8	11.8	17	21	31
5.6	2.8	3	4.6	6.5	12.4
10	1.2	1.4	3.2	5.5	12
18	2.4	4.8	7.2	9.6	19.8
21.9	4.7	6.2	10.4	12.9	23.8
31.5	11.0	14.1	19	24	38
46	29.8	30 (at 17°)	—	—	—

PbCl₂ is readily dissolved by boiling water, but almost all crystallises out on cooling. Insol. alcohol 94 p.c.; somewhat sol. in more dilute. Fairly sol. NaC₂H₃O₂Aq, Na₂S₂O₃Aq, and some other salt solutions. After melting and cooling, PbCl₂ appears as a horn-like mass (hence the name *horn-lead* formerly used).

Reactions.—1. Heated in the air until white fumes cease to come off, a light-yellow oxychloride Pb₂OCl₂ (= PbCl₂.PbO) is formed (*v. Lead, oxychlorides of*).—2. Recently ppd. PbCl₂ when digested with cold neutral lead acetate produces an oxychloride 2Pb₂OCl₂.H₂O (Braudes, *A.* 10, 273).—3. The oxychloride

Pb₂OCl₂.H₂O is obtained by partially ppd. PbCl₂Aq by *lime water*.—4. By adding caustic potash to PbCl₂ suspended in water, the oxychloride PbCl₂.2PbO is said to be formed (Ditte, *C. R.* 94, 1180).—5. According to Berzelius, the product of the action of ammonia on PbCl₂ is PbCl₂.8PbO.4H₂O.—6. Heated in carbon monoxide, COCl₂, and Pb are produced.—7. Heated, not too strongly, in phosphoretted hydrogen, HCl, F, and Pb are formed.—8. Oxidised by alkaline hypochlorites to PbO₂.—9. Long-continued passage of Cl into PbCl₂ suspended in water most probably produces PbCl₂, PbO, being simultaneously ppd. (*v. Fisher, C. J.* 35, 284).

Combinations.—1. PbCl₂ absorbs ammonia gas, forming 2PbCl₂.3NH₃, according to H. Rose. All the NH₃ is readily given off on warming.—2. Combines with lead monoxide, when the two are heated together, to form oxychlorides xPbCl₂.yPbO (*v. Lead, oxychlorides of*).—4. With lead carbonate forms PbCl₂.PbCO₃; obtained by boiling together the two salts; or by the action of CO₂ on PbCl₂ under pressure (Miller, *C. J.* [2] 8, 37).—5. With lead acetate to form PbCl₂.Pb(C₂H₃O₂)₂; obtained by mixing freshly ppd. PbCl₂ with Pb(C₂H₃O₂)₂ and enough glacial acetic acid to form a viscid mass, which soon solidifies, and removing excess of acid by pressure (Carius, *A.* 127, 87).—6. With lead phosphate, forms PbCl₂.Pb₃(PO₄)₂.H₂O and PbCl₂.2Pb₃(PO₄)₂, or according to Gerhardt (*A. Ch.* [3] 22, 505) PbCl₂.Pb₃H₂(PO₄)₂. The former is produced by pouring boiling PbCl₂Aq into excess of boiling Na₂HPO₄Aq; the latter by pouring the Na phosphate into the PbCl₂ solution (Heintz, *P.* 73, 122). *Pyromorphite* PbCl₂.3Pb₃(PO₄)₂ occurs native.—7. Combines with lead bromide to form PbCl₂.PbBr₂, with lead iodide to form PbCl₂.PbI₂, with lead fluoride to form PbCl₂.PbF₂, and with lead sulphocyanide to form PbCl₂.Pb(CNS)₂ (*v. Lead bromochloride, Lead iodobromides, Lead chlorofluoride and Lead chlorosulphocyanide*).—8. Probably combines with chlorine to form PbCl₄, when Cl is passed into PbCl₂ dissolved in considerable excess of HClAq, or when Cl is passed into PbCl₂Aq mixed with CaCl₂ (*v. Lead tetrachloride*).—9. André (*A. Ch.* [6] 3, 104) describes various double compounds of PbCl₂ with NH₄Cl.

LEAD TETRACHLORIDE. (Plumbic chloride.) No other chloride of lead except PbCl₂ has been isolated, but there is considerable evidence in favour of the existence in HCl solution of tetrachloride PbCl₄.

If a considerable quantity of HClAq is added to PbCl₂, and Cl is passed in, the PbCl₂ dissolves to a reddish-brown liquid; on warming Cl is evolved; addition of water causes ppn. of PbO₂.

A mixture of PbCl₂Aq with CaCl₂Aq absorbs much Cl and forms a deep-yellow liquid, which may be preserved unchanged in a closed vessel, but is decomposed in an open vessel giving PbCl₂ and Cl; a few drops of this liquid added to a large quantity of water gives a pp. of PbCl₂ and PbO₂; alkalis and alkaline carbonates ppt. PbO₂; MnCl₂Aq ppts. MnO₂ and PbCl₂; Fe, Cu, Zn, gold leaf, and finely divided Pt, are soluble in the liquid with separation of PbCl₂; it rapidly oxidises many organic bodies, PbCl₂ being ppd.

(Sobrero & Salmi, *A. Ch.* [8] 29, 165; Nicklès, *A. Ch.* [4] 10, 828).

PbO_2 dissolves in cold fairly conc. $HClAq$. From this yellow solution, alkalis, alkaline carbonates, oxides and carbonates of Ba, Mg, Zn, &c., and alkaline borates and acetates, ppt. PbO_2 . The solution smells of Cl, and is decomposed by heat with evolution of Cl and ppt. of $PbCl_2$. If the $HClAq$ is saturated with PbO_2 , the addition of water ppt. PbO_2 . Fisher (*C. J.* 55, 282) determined the ratio of Pb ppt. from this solution by water as PbO_2 to Cl given off by decomposing the solution with ppt. of $PbCl_2$. The ratio was almost exactly $Pb:2Cl$; now this is the ratio required on the hypothesis that the decomposition by water proceeds as shown in equation (1), and the decomposition to $PbCl_2$ and Cl proceeds as shown in equation (2) —

Fisher proved that the whole of the Pb in solution is thrown down by water as PbO_2 . A yellow liquid with properties the same as those of the liquid just described is obtained by treating Pb_2O_3 with a considerable quantity of $HClAq$ (Fisher, *l.c.*).

By the method described above, Sobrero & Salmi (*l.c.*) obtained a double salt $PbCl_2 \cdot 9NaCl$, and Nicklès (*l.c.*) obtained $PbCl_2 \cdot 16CaCl_2$. Evaporation *in vacuo*, over conc. $KOHAq$, of a solution of PbO_2 in $HClAq$ produces crystals of $PbCl_2$ containing some $PbCl_4$, according to Bendant & Daguin (*Ann. M.* [5] 4, 239; v. also Nikolukine, *J. R.* 1885, 207, abstract in *C. J.* 50, 123).

Lead, chlorobromide of; v. *Lead, bromochloride of*.

Lead, chlorocarbonate of; v. *Lead chloride, Combinations No. 4*.

Lead, chlorocyanide of; v. *Lead cyanochloride of*.

Lead, chlorofluoride of. $PbCl_2 \cdot PbF_2$ (= $PbFCl$). Obtained by ppg. boiling $PbCl_2Aq$ by $KFAq$, or $Pb(C_2H_3O_2)_2Aq$ by a solution of 2 parts NaF with 3 parts $NaCl$ (Berzelius). A white powder, slightly soluble in water without decomposition.

Lead, chloriodides of; v. *Lead, iodochlorides of*.

Lead, chlorophosphate of; v. *Lead chloride, Combinations No. 6*.

Lead, chlorosulphide of; v. *Lead, sulphochloride of*.

Lead, chlorosulphocyanide of, $PbCl_2 \cdot Pb(CNS)_2$, by digesting the constituents together, and crystallising from boiling water; slowly changed to PbO_2H_2 by NH_3Aq (Grisson & Thorp, *Am.* 10, 229).

Lead, chromates of; v. vol. ii. pp. 155 and 157.

Lead, cyanides of. None has been isolated, but an *oxycyanide*, and also *ferri-* and *ferrocyanides*, are known; v. vol. ii. pp. 341, 389, and 385.

Lead, cyanochloride of. $PbCl_2 \cdot 2PbCy_2$; by digesting $PbCl_2$ with $KCyAq$ (Grisson & Thorp, *Am.* 10, 229).

Lead, ferriocyanide of; v. vol. ii. p. 389.

Lead, ferrocyanide of; v. vol. ii. p. 385.

Lead, fluochloride of; v. *Lead, chlorofluoride of*.

Lead, fluoride of. PbF_2 . Pb is not acted on by $HFAq$, PbO_2H_2 , or $PbCO_3$, dissolves in $HFAq$, and on evaporating, and heating to remove HF , PbF_2 remains. PbF_2 is also ppt. on adding $Pb(C_2H_3O_2)_2Aq$ to $HFAq$. A white powder; slightly soluble in water; sol. in HNO_3Aq (Berzelius). Gunz (*A. Ch.* [6] 3, 5) gives H.F. of PbF_2 as $[PbO^2H^2 \cdot 2HF] = 24.800$.

Lead, hydroxides of; v. *Lead, oxides and hydrated oxides of*.

Lead, iodide of. PbI_2 . Mol. w. not certainly known, but from analogy of $PbCl_2$, probably 459.46 (= PbI_2). S.G. 6.12; 5-6247 molten at 383° (Rodwell, *T.* 1882, 1144). Melts c. 383° , and boils between 861° and 954° (Carnelley, *C. J.* 33, 277; C. a. Williams, *C. J.* 37, 126). For expansion of PbI_2 , v. Rodwell, *Pr.* 32, 23. H.F. $[Pb, I] = 89,800$ (*Th.* 3, 337).

Preparation. — Solution of $Pb(NO_3)_2$ is added to solution of FeI_2 ; the pp. is washed with cold water and dried. KI or CaI_2 may be used instead of FeI_2 . If $Pb(C_2H_3O_2)_2Aq$ is added to $KIAq$ oxyiodides are formed when excess of Pb salt is added, and soluble double iodides are formed if excess of KI is present; to prevent both results the solution of $Pb(C_2H_3O_2)_2$ should be acidified either with HNO_3 or $C_2H_3O_2$.

Properties and Reactions. — Golden-yellow crystals; hexagonal, $ac = 1:1.3018$ (Norden-skjöld). Melts when heated to a brown-red liquid, and solidifies to a yellow mass. Heated in the air I is evolved, and oxyiodides (*q.v.*) are formed. S. cold water .03; boiling water .515. Decomposed by Cl_2 . Zn or Fe boiled with PbI_2 under water forms ZnI_2 or FeI_2 , and ppts. Pb. $Na_2S_2O_3$, in excess forms Pb sulphite and NaI (Michaelis & Koethe, *B.* 6, 999). NH_3Aq added to boiling PbI_2Aq ppts. $3PbO \cdot PbI_2 \cdot 2H_2O$. Dry PbI_2 is unchanged by light; when moist and exposed to direct sunshine, in contact with the air, it is slowly changed to $PbCO_3$ and PbO_2 , with separation of I ; this change is hastened by all substances which absorb I (Schmid, *P.* 127, 493). PbI_2 is somewhat soluble in conc. solution of alkali iodides, but is ppt. on dilution.

Combinations. — 1. Absorbs ammonia, forming a white compound $PbI_2 \cdot 2NH_3$. — 2. With *lead monoxide* forms various oxyiodides $xPbI_2 \cdot yPbO$ (v. *Lead, oxyiodides of*). — 3. By dissolving PbI_2 in warm *iodhydric acid* solution, and allowing to cool, white lustrous needles of $PbI_2 \cdot 2HI = H_2PbI_4$ separate. This compound may be called *iodo-plumbhydric acid* or *iodo-plumbic acid*; it is decomposed by water; gives off HI *in vacuo*; according to Berthelot, the crystals contain $10H_2O$ (*C. R.* 91, 1024). — 4. PbI_2 combines with *potassium iodide* to form various double salts, one of which, $PbI_2 \cdot 2KI$, seems best regarded as the K salt of H_2PbI_4 . Yellow, lustrous leaflets of $PbI_2 \cdot KI$ are obtained by dissolving the constituent salts in the ratio $PbI_2:KI$ in boiling water, and allowing to cool; by dissolving this salt in warm $KIAq$ and cooling, the salt $PbI_2 \cdot 4KI$ is said to be obtained in white needles (Boullay, *A. Ch.* [2] 34, 366). Remsen (*Am.* 11, No. 5) asserts that the process described by Boullay does not result in production of $PbI_2 \cdot 4KI$, and that the salt formed with most ease when PbI_2 and KI react under different conditions is $PbI_2 \cdot KI \cdot H_2O$ (*cf.* Ditte, *C. R.* 22, 1841). — 5. By mixing a boiling solution of KI

and NH_4Cl with $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$, taking care that no permanent pp. was formed, and cooling, Völkel obtained clear yellow lustrous needles of $\text{PbI}_2 \cdot 2\text{NH}_4\text{Cl}$ (P. 62, 252); decomposed by water with separation of PbI_2 . By saturating hot NH_4ClAq with PbI_2 , cooling, pouring off from $\text{PbI}_2 \cdot 2\text{PbCl}_2$, which separates, and evaporating, Poggiale (C. R. 20, 1180) obtained $\text{PbI}_2 \cdot 4\text{NH}_4\text{Cl} \cdot 2\text{H}_2\text{O}$, decomposed by water with separation of PbI_2 .—6. PbI_2 combines with silver iodide. For properties of the $\text{PbI}_2 \cdot \text{AgI}$ produced v. Rodwell (Pr. 32, 540); Bellati a. Romanese (P. 34, 104).—7. Compounds with lead bromide are formed by crystallising PbI_2 from HBrAq (v. Lead, iodobromides of).—8. Compounds with lead chloride, $\text{PbI}_2 \cdot \text{PbCl}_2$ (= PbICl) and $\text{PbI}_2 \cdot 2\text{PbCl}_2$, are known (v. Lead, iodochlorides of).—9. By boiling PbCO_3 , repeatedly with PbI_2Aq , Poggiale (C. R. 20, 1184) obtained $\text{PbI}_2 \cdot \text{PbCO}_3$.—10. $\text{PbI}_2 \cdot \text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ was obtained by Carius (A. 127, 87) similarly to the PbCl_2 compound (v. Lead chloride, Combinations No. 5).

Lead, iodobromides of. By crystallising PbI_2Aq from HBrAq , Grisson a. Thorp obtained the compounds (1) $\text{PbBr} \cdot \text{PbI}_2$, (2) $3\text{PbBr} \cdot \text{PbI}_2$, (3) $6\text{PbBr} \cdot \text{PbI}_2$ (Am. 10, 229).

Lead, iodicarbonate of; v. Lead, iodide of, Combinations No. 9.

Lead, iodochlorides of. The compound PbClI (= $\text{PbCl}_2 \cdot \text{PbI}_2$) is obtained, in sulphur-yellow prisms, by cooling a solution of PbI_2 in boiling HClAq (Labouret, J. Ph. [3] 4, 328). According to Engelhardt the compound contains more PbI_2 than required by the above formula (J. pr. 67, 293). By saturating hot NH_4ClAq with PbI_2 , and allowing to cool, Poggiale obtained yellow needles of $\text{PbI}_2 \cdot 2\text{PbCl}_2$ (C. R. 20, 1180).

Lead, iodosulphocyanide of, $\text{PbI}_2 \cdot 3\text{Pb}(\text{CNS})_2$; formed with some difficulty by digesting the constituents and crystallising from hot water (Grisson a. Thorp, Am. 10, 229).

Lead, oxides and hydroxides (or hydrated oxides) of. Five oxides of lead have been isolated, viz., Pb_2O , PbO , Pb_2O_3 , Pb_3O_4 , and PbO_2 ; one or more oxides intermediate between Pb_2O and PbO , perhaps exist. Two hydrates of PbO , viz. $2\text{PbO} \cdot \text{H}_2\text{O}$ and $3\text{PbO} \cdot \text{H}_2\text{O}$ are known; the hydrates $\text{Pb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ and $\text{PbO}_2 \cdot \text{H}_2\text{O}$ have also been isolated. The most stable oxide is PbO ; Pb_2O is easily oxidised to PbO by heating in air, and Pb_2O_3 , Pb_3O_4 , and PbO_2 are reduced to PbO when strongly heated. PbO reacts with acids as a basic oxide, forming salts PbX_2 , $\text{X} = \text{NO}_3$, Cl , SO_4 , PO_4 , &c.; it decomposes NH_3 salts, evolving NH_3 , and combines with CO_2 to form PbCO_3 . PbO also reacts with strongly basic oxides as an acidic oxide forming unstable *plumbites*, e.g. K_2PbO_3 . PbO_2 reacts as an acidic peroxide; with KOH and NaOH it forms fairly stable *plumbates*, M_2PbO_4 ; with most acids it forms salts of PbO , but it appears capable of dissolving without reduction in glacial acetic and phosphoric acids. The reactions of Pb_2O_3 and Pb_3O_4 indicate that these oxides are compounds of the form $x\text{PbO} \cdot y\text{PbO}_2$. As none of the oxides of Pb has been gasified the molecular weight of none is known with certainty.

Lead suboxide, Pb_2O . The grey pellicle which forms on the surface of lead exposed to the air consists of Pb_2O , according to Berzelius.

Pb_2O is prepared by heating PbCl_2 in a retort to near 800° as long as any gas is given off; $2\text{PbCl}_2 = \text{Pb}_2\text{O} + \text{CO} + \text{Cl}_2$; the residue is allowed to cool in the retort (Dulong, S. 17, 229; Pelouze, J. pr. 25, 486). Pb_2O is a black powder; S.G. 9.772 (Playfair a. Jodle, C. S. Mem. 3, 88); heated in air it burns to PbO ; heated out of contact with air, PbO and Pb are produced. Moist Pb_2O rapidly absorbs O from the air, forming white $\text{PbO} \cdot x\text{H}_2\text{O}$. Dilute acids resolve Pb_2O into PbO , which dissolves, and Pb; saturated $\text{Pb}_2\text{NO}_3\text{Aq}$ produces a similar resolution, but Pb_2O is wholly soluble in dilute $\text{Pb}_2\text{NO}_3\text{Aq}$. This oxide was at one time supposed to be a mixture of PbO and Pb; but this is disproved by the facts that when the oxide is rubbed with Hg, either dry or under water, no Pb is removed, and that PbO is not removed from it by boiling with Pb acetate solution.

LEAD PROTOXIDE PbO . (Plumbous oxide. Litharge. Massicot.) Mol. w., unknown, as oxide has not been gasified. S.G. 9.277 at 17.5° (Herapath, P. M. 64, 321); 9.25 (Playfair a. Joule, C. S. Mem. 3, 84); 9.15 to 9.88 (Ditte, C. R. 94, 1310); 8.74 to 9.29 (Geuther, A. 219, 60). H.F. [PbO] = 50,300; heats of neutralisation [$\text{PbO} \cdot 2\text{HClAq}$] = 56,830; [$\text{PbO} \cdot \text{HNO}_3\text{Aq}$] = 24,250 to form basic nitrate (Th. 3, 337). Crystallises in rhombic forms $a:b:c = 666:1:971$ (Nordenskjöld, P. 114, 619; v. also Mitscherlich, P. 49, 403; J. pr. 19, 451; Grailich, W. A. B. 28, 282; Marx, J. pr. 3, 217). PbO is dimorphous according to Ditte (C. R. 94, 1310).

Occurrence.—As *lead-ochre*, in small quantities in Mexico, Baden, Virginia, and a few other localities.

Formation.—1. By heating Pb to low redness in presence of air; if the temperature is kept below the melting-point of the PbO , the oxide is obtained as a yellowish powder, known commercially as *massicot*; if the PbO is melted during the preparation, the oxide solidifies to a scaly reddish solid known as *litharge*.—2. By heating Pb with KNO_3 .—3. By strongly heating red lead in air.—4. By strongly heating 'white lead' on an iron plate.—5. By adding boiling Pb acetate solution to boiling KOH Aq ; pp. is crystalline (Winkelblech, A. 21, 21; J. pr. 10, 227).—6. By slowly pouring Pb acetate solution into CaOAq at 80° until a crystalline crust appears, then adding a little more, and allowing to cool (Brondecke, R. P. 55, 318).—7. By adding PbSO_4 , made into a paste with water, to boiling NaOHAq (Wichmann, C. C. 1860, 334). For modifications of these processes v. Payel, J. pr. 13, 485; Böhrens, B. J. 24, 134.—8. According to Yorke (P. M. [3] 5, 82), crystals of PbO are produced by placing Pb in a vessel of water exposed to the air. The reaction of steam with Pb at white heat produces PbO .

Preparation.—1. Basic Pb nitrate is heated in a Pt crucible until completely decomposed (the neutral salt melts before decomposition is complete). Berzelius recommends the following procedure. Equal weights of PbO and Pb_2NO_3 are kept in boiling water until the PbO is wholly transformed into basic nitrate; the basic salt is dissolved in boiling water, the solution is filtered hot and allowed to cool; the basic nitrate which separates is subjected to the action of the boiling solution as long as any solid separates on cooling.

A small quantity of the basic nitrate is made into a paste with water, the inside of a Pt crucible is covered with this paste, and the crucible is dried; the rest of the salt is strongly pressed while moist, then dried, and broken into smaller pieces, which are placed in the crucible, which is then heated until the decomposition is completed. The PbO formed from the pieces of basic nitrate in the middle of the crucible is pure; the outer layers of PbO contain a little Pt.—2. PbO is prepared in crystalline form by dissolving PbO, prepared as in 1, in hot KOHAq or NaOHAq and allowing to cool. The colour and S.G. of the crystals vary with the conditions. Ditte (*C. R.* 94, 1810) obtained a greenish crystalline mass (S.G. 9.1699) by heating KOHAq c. 13 p.c. with $\text{PbO} \cdot x\text{H}_2\text{O}$; using 25 p.c. KOHAq he obtained sulphur-yellow lustrous crystals (S.G. 9.2089); brownish needles (S.G. 9.8835) were obtained by using 30 p.c. KOHAq and allowing to cool; KOHAq 18.5 p.c., saturated with $\text{PbO} \cdot x\text{H}_2\text{O}$ when hot, gave deep green, almost black, crystals on cooling (S.G. 9.5605); saturated KOHAq boiled with $\text{PbO} \cdot x\text{H}_2\text{O}$ gave deep rose-coloured crystals of PbO (S.G. 9.4223), differing in form from the usual crystals, and becoming yellow when strongly heated (*cf.* Mitscherlich, *J. pr.* 19, 454; Calvert, *B. J.* 24, 135; Bequerel, *A. Ch.* [3] 51, 105).

Properties.—PbO is a yellow to reddish-yellow crystalline solid; the colour and S.G. of the oxide when well crystallised seem to vary with the conditions of formation, *v. Preparation*, No. 2. Melts between 585° and 630° to a clear dark-red liquid. According to Leblanc (*B. J.* 26, 193) molten PbO absorbs O, which it gives off on solidifying. PbO is sl. sol. water; 1 part dissolves in c. 7000 water; the solubility is affected by the state of aggregation of the PbO (*cf.* Bineau, *C. C.* 1855, 877); if the solution is exposed to the air CO_2 is absorbed, and the Pb ppd. as basic carbonate; the PbO is also removed by filtration through paper (Yorke, *P. M.* [3] 5, 82). Heated to between 300° and 450° in air, PbO is oxidised to Pb_2O_3 , but at higher temperatures Pb_2O_3 is deoxidised to PbO. PbO is soluble in warm conc. KOHAq or NaOHAq. Geuther (*A. J.* 29, 56) says that two varieties of PbO exist, one yellow and the other red; the yellow crystallises in rhombic, the red in hexagonal, forms.

Reactions.—1. Heated in air Pb_2O_3 is formed at c. 800°–450°; at a somewhat higher temperature PbO is re-formed.—2. Heated in hydrogen, or carbon monoxide, reduction to Pb occurs at a little above 100°; PbO is also reduced to Pb by heating with C, Na, or KCN.—3. Reacts with most acids to form salts PbX_2 , $\text{X} = \text{NO}_3, \text{Cl}, \text{SO}_4$, &c.; absorbs CO_2 from the air forming PbCO_3 .—4. Decomposes alkali salts with separation of the alkali.—5. Dissolves in warm fairly conc. potash or soda solution, probably with formation of plumbites $\text{K}_2(\text{Na})_2\text{PbO}_2$.—6. Dissolves in molten potash forming K_2PbO_2 , which, on long-continued heating in air, is oxidised to K_2PbO_3 (Carnegie, *O. N.* 60, 113) (*v. PLUMBATES* under LEAD PEROXIDE, p. 132).—7. Dissolves also by boiling with milk of lime on evaporating in absence of air a compound separates in needles, probably CaPbO_2 .—8. Molten PbO dissolves silica, easily forming glass-like silicates; these

silicates readily dissolve CaO , Al_2O_3 , &c.—9. Heated in chlorine, bromine, or iodine vapour, the compound PbCl_2 , PbBr_2 , or PbI_2 is formed; heated with Cl and air, Br and air, or I and air, the product is $\text{Pb}_2\text{Cl}_2\text{O}$, $\text{Pb}_2\text{Br}_2\text{O}$, or $\text{Pb}_2\text{I}_2\text{O}$ (Cross a. Sigiura, *C. J.* 83, 405).—10. By boiling excess of PbO with conc. calcium chloride solution, filtering, and washing with alcohol the pp. that forms on cooling, André (*C. R.* 104, 359) obtained $2\text{PbO} \cdot \text{CaO} \cdot \text{CaCl}_2 \cdot 4\text{H}_2\text{O}$; by using strontium chloride he obtained $2\text{PbO} \cdot \text{SrCl}_2 \cdot 5\text{H}_2\text{O}$.—11. PbO does not react with phosphorus trichloride at 160°, but when heated together over a flame, PbO and PCl_3 react violently forming PbCl_2 , $\text{Pb}(\text{H}_2\text{PO}_3)_2$, and P (Michaelis, *J. pr.* [2] 4, 449).—12. Dissolves in magnesium chloride solution; on filtering and evaporating, the oxychloride $3\text{PbO} \cdot \text{PbCl}_2 \cdot \text{H}_2\text{O}$ separates (Voigt, *Chem. Zeitung*, 13, 695).

HYDRATES OF LEAD MONOXIDE.—1. $3\text{PbO} \cdot \text{H}_2\text{O}$; obtained by adding c. 400 grms KOH to 1000 cc. water containing freshly ppd. PbO in suspension (Ditte, *C. R.* 94, 1810); also by adding basic Pb acetate solution to NH_4Aq at 20°–25°, and digesting the pp. under the liquid for some time (Payen, *A. Ch.* [4] 8, 302; Behrens, *B. J.* 24, 134). This hydrate forms lustrous octahedral crystals; S.G. 7.592 at 0° (Ditte, *C. R.* 94, 1810); loses some H_2O at 130°, and is entirely dehydrated at 145°; a. sol. caustic alkali solutions.—2. $2\text{PbO} \cdot \text{H}_2\text{O}$. By pp. $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Aq}$ by KOHAq or NaOHAq, and digesting with excess of pptant; if $\text{Pb}(\text{NO}_3)_2$ is used some basic nitrate is always formed (Schaffner, *A.* 51, 175). The hydrates of PbO readily absorb CO_2 from the air; they also combine with NH_3 to form $\text{PbO} \cdot \text{H}_2\text{O} \cdot 2\text{NH}_3$ and $8\text{PbO} \cdot 2\text{NH}_3 \cdot \text{H}_2\text{O}$ (Calvert, *C. R.* 23, 480).

Plumbites. Although PbO is a markedly basic oxide, it nevertheless dissolves in alkali solutions to form unstable salts of the form M^+PbO_2 ; these salts, plumbites, have not been much investigated; according to Carnegie (*C.N.* 60, 113) K plumbite is formed by dissolving PbO in molten KOH, and on long-continued heating in air it is oxidised to plumbate K_2PbO_3 . The Ag salt is produced by adding NaOHAq to a mixture of a Pb and a Ag salt; Wöhler gives the formula $\text{Ag}_2\text{O} \cdot 2\text{PbO}$. Krutwig (*B.* 15, 1264) obtained a yellow salt, $\text{Ag}_2\text{PbO}_3 \cdot 2\text{H}_2\text{O}$, by adding $\text{AgNO}_3 \cdot \text{Aq}$ to alkaline $\text{Pb}(\text{NO}_3)_2 \cdot \text{Aq}$, and washing with hot KOHAq and then with hot water; the salt soon became black in the air.

LEAD SESQUIOXIDE. Pb_2O_3 . (*Plumbo-plumbic oxide*.) Mol. w. unknown, as oxide has not been gasified. A reddish-yellow powder resembling PbO ; Debray describes Pb_2O_3 as greenish-brown (*C. R.* 86, 518). Debray (*l.c.*) prepares this oxide by heating PbO to 350°, or by heating PbO or better PbCO_3 to the same temperature in a stream of air or O; Carnelley a. Walker (*C. J.* 53, 85) say that PbO is changed to Pb_2O_3 at 280°–200°, and that Pb_2O_3 gives off O at c. 870°. According to Jacquelin (*J. pr.* 53, 158) Pb_2O_3 may be obtained by pouring a solution of red lead, Pb_3O_4 , in glacial acetic acid into very dilute NH_4Aq , separating the pp. quickly, washing it with hot water containing a very little acetic acid, and drying at 100°. Winkelblech (*A.* 21, 21) obtained this oxide by pouring NaOHAq into $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Aq}$ until the pp. dissolved, and then

adding cold NaClO_4aq , taking care to avoid excess which would produce PbO_2 . Debray asserts that this method yields only a mixture of PbO and PbO_2 . Pb_2O_3 is not decomposed by heat until $c. 860^\circ$, but a little above this temperature it gives off O , leaving Pb_2O_3 ; heated to $c. 530^\circ$, PbO is produced (Carnelleya, Walker, *C.J.* 53, 85). Pb_2O_3 is resolved by acids into PbO , and a salt of PbO ; Winkelblech's statement that Pb_2O_3 is dissolved unchanged by HClAq , from which solution it may be pptd. again by alkalis, is denied by Hausmann (*A.* 91, 235). Pb_2O_3 is reduced to PbO by $\text{H}_2\text{C}_2\text{O}_4\text{aq}$ or $\text{H}_2\text{CO}_3\text{aq}$.

HYDRATE OF LEAD SESQUIOXIDE. $\text{Pb}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. Obtained by adding PbO to conc. $\text{K}_2\text{PbO}_4\text{aq}$, as a red curdy pp. (Seidel, *J. pr.* [2] 20, 200). The solution of K_2PbO_4 is obtained by dissolving pure PbO in molten KOH with a very little water, and then dissolving the fused mass in a small quantity of water.

RED OXIDE OF LEAD. Pb_2O_3 . (*Diplumboplumbic oxide. Red lead. Minium.*) Mol. w. unknown, as oxide has not been gasified. S.G. 9.096 at 15° (Herapath, *P. M.* 64, 321).

Occurrence.—*Minium* is found mixed with other lead ores in Yorkshire, Anglesey, Virginia, the Eifel, &c.

Formation.—By heating PbO in air to low redness (not above 450°) for some time, and cooling slowly.—2. By adding PbO in KOHaq to $\text{K}_2\text{PbO}_4\text{aq}$, washing the pp. with hot water, and heating it.—3. Finely divided ppd. Pb exposed to air in presence of water and a little NH_4aq is slowly changed to Pb_2O_3 , mixed with Pb carbonate (Schönbein, *J. pr.* 74, 323).

Preparation.—1. A mixture of 1 pt. KClO_4 , 4 pts. PbO (prepared by heating PbCO_3), and 8 pts. KNO_3 is heated; the mass melts, and PbO_2 is formed and on continued heating is changed to Pb_2O_3 ; the fused mass is treated with water and the residue is boiled with dilute KOHaq , to dissolve unchanged PbO , washed and dried (Levol, *J. pr.* 22, 38).—2. 5 to 6 pts. $\text{Pb(NO}_3)_2$ are dissolved in water, and KOH is added until the pp. which forms is dissolved, to this liquid is added 1 pt. PbO_2 and the whole is boiled for some time; unchanged PbO_2 is decomposed by digesting with $\text{H}_2\text{C}_2\text{O}_4\text{aq}$, and the Pb_2O_3 formed is dissolved in KOHaq ; the residue is washed and dried (Levol, *loc. cit.*).—3. Commercial red lead usually contains some PbO ; this may be removed by digestion with dilute acetic acid, or better with lead acetate solution. Löwe (*D.F.J.* 271, 472) recommends to digest 1 pt. commercial red lead with 10–15 pts. of a 10 p.c. solution of $\text{Pb(NO}_3)_2$, for some time at a gentle heat, then to boil, and finally wash well.

Properties.—A scarlet crystalline-granular powder; when heated it becomes brighter red and then violet; at $c. 500^\circ$ – 530° decomposition to PbO and O occurs. S.G. according to different observers varies from 8.94 to 9.1 (v. Clarke's *Specific Gravity Tables* (2nd ed.), p. 47). Insol. water; reacts with dilute acids to form salts of PbO , and PbO_2 , which remains undissolved; with conc. H_2SO_4 or HClAq , gives salts of PbO and O or Cl . Dissolves completely in glacial acetic acid forming a liquid which acts as an energetic oxidiser (v. *Reactions*, No. 6). Pb_2O_3 is readily reduced to PbO , e.g. by SO_2aq or HNO_2aq .

Reactions.—1. Heated to $c. 500^\circ$ – 530° , gives

PbO and O .—2. Reduced to PbO by easily oxidised bodies, e.g. SO_2aq , HNO_2aq , solution of sugar.—3. With stannous chloride gives PbCl_2 and SnCl_4 .—4. Dissolves in considerable quantity of conc. cold *hydrochloric acid* to form a yellow liquid from which alkalis, alkaline carbonates, borates, and acetates, and oxides and carbonates of Ba , Mg , Zn , &c. ppt. PbO_2 ; on heating, the solution decomposes to PbCl_2 and Cl ; this solution almost certainly contains PbCl_4 , on warming Cl is evolved and PbCl_2 pptd. (Fisher, *C. J.* 35, 282; v. *Lead tetrachloride*, p. 126). Dilute HClAq forms PbCl_2 , H_2O , and PbO_2 . Warm HClAq in excess evolves Cl and ppts. PbCl_2 .—5. Dilute sulphuric, nitric, or acetic acid, and other dilute acids ppt. PbO , and form sulphate, &c. of PbO . Hot conc. H_2SO_4 forms PbSO_4 and O .—6. Pb_2O_3 dissolves in glacial acetic acid; this solution is strongly oxidising, e.g. it converts SO_2aq to SO_4aq , $\text{As}_2\text{O}_3\text{aq}$ to $\text{As}_2\text{O}_5\text{aq}$, PbS to PbSO_4 , Pb , Hg , and Cu to oxides, separates I from KI (Schönbein, *J. pr.* 74, 315); when dropped into dilute NH_4aq a pp. of PbO_2 is produced (Jacquelin, *J. pr.* 53, 153; v. *Lead sesquioxide*, p. 129). According to Jacquelin (*loc. cit.*) a solution of Pb_2O_3 in glacial acetic acid at 40° gives crystals of $\text{PbO}_2(\text{C}_2\text{H}_3\text{O}_2)_4$, [$\text{O}=8$, $\text{Q}=6$] (old notation); these crystals may be kept under acetic acid but give PbO_2 and $\text{H}_2\text{C}_2\text{O}_4$ on warming, or with water. Schönbein (*J. pr.* 74, 315) says that conc. acetic acid dissolves about 9 p.c. of Pb_2O_3 , when shaken for 15 mins. with excess of the finely powdered oxide; the solution is easily decomposed by heat or dilution, but is stable at $c. -18^\circ$; by careful addition of H_2SO_4 , PbSO_4 is pptd. and an acetate corresponding to PbO_2 remains in solution; this solution deposits PbO_2 slowly at ordinary temperatures, quickly when heated; addition of KOHaq does not ppt. Pb_2O_3 , but a mixture of PbO and PbO_2 .—7. Pb_2O_3 dissolves in conc. phosphoric acid; the solution reacts similarly to that of PbO_2 in acetic acid. By using a mixture of phosphoric and sulphuric acids, a solution is obtained containing only the phosphate corresponding to PbO_2 , and free from PbO (Jacquelin, *J. pr.* 53, 152; v. *Lead peroxide*, p. 131).—8. Conc. solutions of arsenic and tartaric acids dissolve Pb_2O_3 ; the solutions resemble those in acetic and phosphoric acids, but are more easily decomposed.

Composition and constitution of red lead.—

When PbO is heated in air, O is slowly and continuously absorbed; when $c. 1.76$ p.c. O has been absorbed this product is red, but absorption of O continues, and some specimens of red lead contain 2.67 p.c. O in excess of that contained in the PbO (Jacquelin, *J. pr.* 53, 151). An absorption by PbO of 1.79 p.c. O corresponds with the formation of Pb_2O_3 ; the formation of Pb_2O_3 requires 2.89 p.c. Older analyses of red lead led to the supposition that it was Pb_2O_3 (Dumas, *B. J.* 13, 113). Careful syntheses and analyses have, however, shown that a definite red-coloured oxide exists having the composition Pb_2O_3 . At the same time the analyses of commercial red leads made by Mulder (*J. pr.* 50, 488) and Jacquelin (*J. pr.* 53, 151) show that the percentage of O above that required to form PbO varies from 1.16 to 2.67. Several samples of red lead agreed in composition with the formula Pb_2O_3 .

others approached Pb_3O_2 (cf. Löwe, *D. P. J.* 271, 472). It is still doubtful whether a series of oxides exists of the form $xPbO \cdot yPbO_2$, x varying from 1 to 3 or 4 and y from 1 to 2 or 3, or whether only two such oxides are definite bodies, viz. $PbO \cdot PbO_2 (= Pb_2O_3)$ and $2PbO \cdot PbO_2 (= Pb_3O_4)$.

Red lead, Pb_3O_4 , may be regarded either as $2PbO \cdot PbO_2$ or as $PbO \cdot Pb_2O_3$; the reaction of Pb_3O_4 with acids, the synthesis of Pb_3O_4 by the action of PbO in KOHAq on $K_2PbO_3 (= K_2O \cdot PbO_2)$, and the fact that PbO_2 is acidic towards some oxides, point to the constitution $2PbO \cdot PbO_2$, rather than $PbO \cdot Pb_2O_3$.

LEAD PEROXIDE. PbO_2 . (*Brown oxide of lead. Puce oxide of lead. Lead dioxide.*) Mol. w. unknown, as oxide has not been gasified. S.G. 8.902 at 16.5° (Herapath, *P. M.* 64, 321); 8.756 to 8.897 (Playfair & Joule, *C. S. Mem.* 3, 84); 9.045 (Wernicke, *P.* 141, 109).

Occurrence.—As *plattnerite*, at Leadhills, in hexagonal prisms.

Formation.—1. By boiling a Pb salt with a filtered solution of bleaching powder.—2. By digesting red lead with dilute HNO_3 Aq, and washing the residue.—3. By mixing solutions of Pb acetate (4 pts.) with soda crystals (3 pts.), and passing Cl into the mixture: 2 pts. PbO_2 are obtained; $PbCl_2$ is not formed (Vöhler, *J. pr.* 90, 383; cf. Geuther, *A.* 96, 382).—4. By heating PbO with $KClO_3$ to less than red heat and washing the mass with water.—5. By boiling $PbO \cdot xH_2O$ with K_2FeCy_6 Aq in presence of KOH ($2K_2FeCy_6$ Aq + $2KOH$ Aq + $PbO = 2K_2FeCy_6$ Aq + $PbO_2 + H_2O$; Overbeck, *Ar. Ph.* [2] 85, 5).—6. By fusing PbO with KOH for some time (Bequerel, *A.Ch.* 51, 504). Carnegie (*C. N.* 60, 113) obtained $PbO_2 \cdot H_2O$ by long-continued fusion of PbO in KOH solution in water, and careful neutralisation by dilute H_2SO_4 Aq (*v. Hydrates of lead peroxide, infra*).—7. By oxidising PbO by an alkaline solution of $KMnO_4$ (Reynoso, *C. R.* 32, 646).—8. By electrolysis strongly alkaline solutions of Pb salts, the hydrate $PbO_2 \cdot H_2O$ (*q.v.*) is deposited on the positive electrode (Bequerel, *A.Ch.* [3] 8, 405). By slowly electrolysis a solution of 1 pt. $Pb(NO_3)_2$ in 8 pts. water, Wernicke obtained PbO_2 (*P.* 141, 109).—9. PbO_2 is obtained, mixed with PbO , by shaking basic Pb acetate with H_2O_2 Aq (Schönbein, *J. pr.* 75, 88).

Preparation.—1. Very finely powdered Pb acetate is boiled with a filtered solution of bleaching powder, the liquid being poured off, and fresh solution added from time to time, until no Pb is found in solution; the residue is washed with very dilute HNO_3 Aq, and then with hot water, and dried at a low temperature (Böttger, *J. pr.* 73, 493).—2. Fehrmann (*B.* 15, 1882) recommends to add a filtered solution of bleaching powder to conc. $PbCl_2$ Aq at 50° to 60°, until a few drops of the supernatant liquid cease to show a brown colour when filtered, and to wash the pp. out of contact with air.

Properties.—A dark puce-brown powder; black according to Fehrmann (*B.* 15, 1882). The native compound forms metal-like, lustrous iron-black, hexagonal crystals; S.G. 9.892 to 9.448 (Breithaupt, *J. pr.* 10, 508). When heated, PbO_2 gives Pb_2O_3 and O, and at a higher temperature it is resolved into PbO and O. Readily

parts with O to oxidisable bodies, e.g. rubbed with P or S vivid combustion occurs; sugar and gallic acid &c. are ignited by saturation with PbO_2 . Acids generally react with PbO_2 to form salts of PbO ; cold conc. HCl Aq seems to produce $PbCl_2$, and solutions of Pb_2O_3 in glacial acetic and phosphoric acids probably contain salts corresponding with PbO_2 (*v. Reactions*, No. 9). PbO_2 reacts with strongly basic oxides as an acidic oxide to form plumbates $M_2 \cdot PbO_3$ (*v. infra, Plumbates*). On account of its readiness to part with O, PbO_2 is largely used for forming a surface on which to strike 'safety' matches.

Reactions.—1. Heated, easily goes to Pb_2O_3 and O, and at a higher temperature to PbO and O.—2. Readily gives up $\frac{1}{2}$ of its O to easily oxidised bodies, either at the ordinary temperature or by slightly heating; e.g. when PbO_2 is rubbed with an equal weight of $H_2C_2O_4$, H_2O , CO_2 , and $PbCO_3$ are formed; PbO_2 rubbed with $\frac{1}{2}$ pt. sugar or $\frac{1}{4}$ pt. tartaric acid oxidises these rapidly, causing ignition; P is oxidised and ignited when rubbed with PbO_2 (*v. Böttger, A.* 34, 94).—3. Sulphur dioxide is rapidly absorbed by PbO_2 with rise of temperature and production of SO_2 .—4. Potassium iodide is decomposed with liberation of I.—5. PbO_2 reacts with a dilute solution of potassium ferrocyanide to form K_2FeCy_6 , provided the KOH produced in the reaction is neutralised by CO_2 ; with conc. potassium ferricyanide solution in presence of KOH, K_2FeCy_6 is formed.—6. By digesting PbO_2 with ammonia solution, PbO , H_2O , and NH_4NO_3 are produced.—7. Not acted on by cold nitric or sulphuric acid; with hot conc. H_2SO_4 gives $PbSO_4$ and O.—8. Cold conc. hydrochloric acid in excess dissolves PbO_2 , producing a yellow liquid which evolves Cl on heating and gives a pp. of $PbCl_2$; alkalis, alkaline carbonates, and alkaline earth oxides and carbonates ppt. PbO_2 from this solution; the solution almost certainly contains $PbCl_2$ (*v. Lead tetrachloride, p.* 126). Hot HCl Aq evolves Cl and forms $PbCl_2$.—9. A basic acetate derived from PbO_2 is said by Jacquelin (*J. pr.* 53, 152) to be obtained by dissolving red lead in glacial acetic acid at 40° and cooling; J. gives the formula $PbO_2(C_2H_3O_2)_2$, [O = 8, C = 6] [old notation] to the crystals which form. These crystals are unchanged in acetic acid; on drying between paper, or on adding water, they are resolved into PbO and acetic acid. Similar salts derived from PbO_2 are obtained by dissolving red lead in very conc. phosphoric and arsenic acids, but the salts are very unstable (*J. l.c.*; cf. *Red oxide of lead, Reactions*, No. 6, p. 130).—10. Heated with phosphorus trichloride, $PbCl_3$, $POCl_3$, and $Pb(H_2PO_3)_2$ are formed (Michaëlis, *J. pr.* [2] 4, 449).—11. Heated in chlorine, bromine, and iodine, the compounds $Pb_2Cl_2O_2$, $Pb_2Br_2O_2$, and $Pb_2I_2O_2$, respectively, are obtained; heated in chlorine and air, bromine and air, and iodine and air, the products are $Pb_2Cl_2O_2$, $Pb_2Br_2O_2$, and $Pb_2I_2O_2$, respectively (Cross & Sigura, *C. J.* 33, 405).—12. PbO_2 reacts with alkalis to form compounds in which PbO_2 forms the negative radicle; e.g. the salt K_2PbO_4 may be obtained from a solution in conc. hot KOHAq (*v. infra, Plumbates*).

HYDRATES OF LEAD PEROXIDE. (1) $PbO_2 \cdot H_2O$. This hydrate is formed, as a brown pp., by dis

solving PbO in molten KOH, heating in air for a considerable time, dissolving the K_2PbO_2 produced in cold water, and *exactly neutralising* by dilute H_2SO_4 (Carnegie, *C. N.* 60, 118). It is also probably obtained at the positive electrode, by the electrolysis of strongly alkaline solutions of Pb salts (Becquerel, *A. Ch.* [3] 8, 405). By electrolysis of an alkaline solution of Pb-Na tartrate, Wernicke (*P.* 141, 109) obtained a lustrous blue-black film, which had the composition $PbO_2 \cdot H_2O$, S.G. 6.267. (2) According to Carnelle and Walker (*C. J.* 53, 85), ppd. PbO_2 after drying in the air for 10 days has very nearly the composition $3PbO_2 \cdot H_2O$; at 230° this hydrate is changed to PbO_2 .

Plumbites.— PbO_2 reacts with acids as a basic peroxide forming salts corresponding with PbO_2 ; in some cases unstable salts derived from PbO_2 appear to be produced (*v. supra*, *Lead peroxide*, *Reactions* 8 and 9). PbO_2 also reacts with alkalis as an acidic oxide to form salts $M'PbO_3$ known as *plumbites*. Fremy (*C. R.* 15, 1109) obtained colourless crystals of $K_2PbO_3 \cdot 3H_2O$ by dissolving PbO_2 in boiling very conc. KOH, adding a little water, and placing over H_2SO_4 . Seidel (*J. pr.* [2] 20, 200) obtained the salt by adding PbO_2 to molten KOH containing a little water, dissolving the fused mass in water, and evaporating over H_2SO_4 *in vacuo*. The crystals form quadratic octahedra, *a:c* = 1:1.2216; they are decomposed by water with separation of PbO_2 . A corresponding Na salt is known. Solutions of these salts are said to yield pps. of plumbites when added to solutions of various metallic salts. K_2PbO_3 is also produced by dissolving PbO in molten KOH and heating in air (Becquerel, *A. Ch.* 51, 504; Carnegie, *C. N.* 60, 113). Crum obtained a plumbite of Ca by digesting $Pb(NO_3)_2$ with CaO and bleaching powder (*A.* 55, 213). For PLUMBATES *v.* Kassner (*Ar. Ph.* 232, 375 [1894]).

Lead, oxybromides of. Several oxybromides of Pb are known. The compound $PbO \cdot PbBr_2$ is formed by heating $PbBr_2$ in air so long as white fumes are evolved; also by digesting $PbBr_2$ with solution of Pb acetate. By heating PbO in Br vapour, Cross and Sigiura obtained $Pb_3Br_4O_5$; and by heating the same oxide in a mixture of Br and air they obtained $Pb_3Br_4O_5$ (*C. J.* 33, 405); from PbO_2 they obtained $Pb_3Br_4O_5$ by heating in Br.

Lead, oxychlorides of. $PbCl_2$ and PbO very readily combine when heated together to form oxychlorides from which HNO_3 dissolves out PbO .

$PbCl_2 \cdot PbO$: occurs native as *matlockite*, S.G. 7.21 (Greg, *P. M.* [4] 2, 120; Ramsdell, *P.* 75, 141); formed by heating $PbCl_2$ in air until fumes are no longer evolved; also by digesting freshly ppd. $PbCl_2$ with cold Pb acetate solution (the oxychloride thus formed is $(PbCl_2 \cdot PbO) \cdot H_2O$ according to Brandes, *A.* 10, 273); also (with H_2O) by partial ppn. of $PbCl_2$ by CaO , thus prepared it is used as a pigment (*Pattinson's white lead*).

$PbCl_2 \cdot 2PbO$: occurs native as *mendipite*, in yellow-white trimetric prisms, S.G. 7 to 7.1; formed, according to Ditte (*C. R.* 94, 1180), by gradually adding KOH to $PbCl_2$ suspended in water, or by adding $KClO_4$ to $PbO \cdot 2H_2O$.

$PbCl_2 \cdot 3PbO$: the hydrate with $4H_2O$ is

formed by adding NH_3 to $PbCl_2$ (Berzelius); also by mixing NaCl with PbO, making into a paste with water, and allowing to stand; the product of this reaction, when washed and heated, gives a yellow powder, known as *Turner's yellow*, which is probably $PbCl_2 \cdot 3PbO$. The hydrate $PbCl_2 \cdot 3PbO \cdot H_2O$ was obtained by Voigt (*Chem. Zeitung*, 18, 695) by dissolving PbO in $MgCl_2$, filtering, and evaporating.

$PbCl_2 \cdot 7PbO$: a lustrous, golden-yellow, crystalline mass, obtained by melting together 1 pt. pure NH_4Cl and 10 pts. pure PbO, pouring off from a little Pb (formed by the reducing action of NH_3 set free by the PbO acting on NH_4Cl), and allowing to cool; known as *Cassel yellow*.

By heating PbO in a mixture of Cl and air, Cross and Sigiura obtained $Pb_3Cl_4O_5$ (*C. J.* 33, 405), by heating PbO_2 in Cl the product was $Pb_3Cl_4O_5$, and by heating PbO_2 in a mixture of Cl and air the compound $Pb_3Cl_4O_5$ was obtained.

According to André (*A. Ch.* [6] 3, 104) $PbCl_2 \cdot PbO$, $PbCl_2 \cdot 2PbO$, and $PbCl_2 \cdot 3PbO$ are obtained by ppg. $PbCl_2$ by KOH.

Lead, oxycyanide of; *v.* vol. ii. p. 341.

Lead, oxyiodides of. Several oxyiodides of lead are known. $PbI_2 \cdot PbO \cdot H_2O$ is formed by adding KI to excess of Pb acetate solution and digesting the pp. in the liquid; it is a yellowish-white powder, insol. water (Brandes, *A.* 10, 269; cf. Ditte, *C. R.* 92, 145). Other oxyiodides, described by Kühn (*Ph. C.* 1847, 593) and Denot (*J. Ph.* 20, 1) are $PbI_2 \cdot 2PbO \cdot H_2O$, $PbI_2 \cdot 3PbO \cdot 2H_2O$, and $PbI_2 \cdot 5PbO$. Cross and Sigiura (*C. J.* 33, 405) describe the oxyiodides $Pb_3I_4O_5$, $Pb_3I_4O_5$, $Pb_3I_4O_5$, and $Pb_3I_4O_5$, obtained by heating PbO_2 and PbO , in I and air, and in I only.

Lead, phosphide of. No phosphide of Pb has been isolated with certainty. Pelletier (*A. Ch.* [2] 13, 114) said that Pb takes up c. 15 p.c. P when P is thrown on to melted Pb, or when Pb filings are strongly heated with glacial phosphoric acid, or $PbCl_2$ with P; but the experiments of Cloud (in Percy's laboratory) make it doubtful whether Pb and P combine. According to H. Rose (*P.* 24, 326) a brown pp., consisting of a phosphide of Pb, is obtained by passing PH_3 into Pb acetate solution.

Lead, salts of. *Compounds formed by replacing the H of acids by Pb.* Pb forms one series of well-marked salts, PbX_n , where $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{2}CO_3, \frac{1}{2}PO_4, \frac{1}{2}AsO_4$, &c. $PbCl_2$ very probably exists in a solution of PbO_2 or Pb_2O_3 in cold conc. HCl ; and $PbO(C_2H_3O_2)_2$ is said to have been isolated; these two salts belong to the series PbX_n , corresponding with the oxide PbO_2 . Very many basic salts of Pb are known, and a considerable number of double salts. The formulae of the Pb salts are determined from analyses, comparison with the salts and compounds of Sn, Ge, and Si, and from the vapour densities of $PbCl_2$ and $PbMe_4$. The following are the chief salts of lead (*v.* CARBONATES, NITRATES, SULPHATES, &c.): *Antimonate, arsenate and -ite, borate, bromate, carbonates, chlorate and -ite, chromates, dithionate, hypophosphite, iodate, molybdate, nitrates and -ites, pentathionate, perchlorate, periodates, phosphates and -ites, sulphates and -ites, selenite and -ite, silicates, thiosulphate, trithionate, tungstates, uranate, vanadates.*

Lead, selenide of, $PbSe$. Occurs native as *clausenthalite* in the Hartz, &c., the Pb being sometimes partly replaced by Co, Cu, Hg, Ag, &c.; S.G. 7 to 8.8 (H. Mose, P. 2, 416; 3, 281; Stromeyer, P. 2, 408; Kersten, P. 46, 265). $PbSe$ is produced by heating the constituents in the ratio $Pb:Se$; it forms a porous, grey, soft mass (Berzelius); melted under borax small regular crystals are obtained, S.G. 8.154 (Little, A. 112, 212). Heated in air Se is vaporised, then a little $PbSe$, and a residue of basic selenite of Pb is left; cold HNO_3 dissolves Pb , leaving Se .

Lead, selenocyanide of, $Pb(SeCy)_2$; v. vol. ii. p. 348.

Lead, silicofluoride of, $Pb(BF_4)_2$. Long prismatic crystals; by dissolving PbO in HBF_4 and evaporating to a syrup; partially decomposed by water or alcohol (Berzelius, P. 2, 113).

Lead, sulphides of. Besides PbS , which is a well-marked compound, two subsulphides, Pb_2S and Pb_3S , probably exist; there are also indications of the formation of a persulphide.

LEAD SULPHIDE. (Lead monosulphide. *Plumbous sulphide*.) PbS .

Occurrence.—Native as *galena*; crystallised in monometris octahedra, and cubic and rhombic dodecahedra; S.G. 7.25 to 7.7 (v. Neumann, P. 23, 1).

Preparation.—1. By mixing S with molten Pb .—2. By heating PbO with excess of S .—3. By the action of H_2S or an alkaline sulphide on Pb salts.—4. By passing CS_2 over Pb heated a little above redness, crystals of PbS are formed (Pb thiocarbonate seems to be also produced) (Gautier a. Hallopeau, C. R. 108, 111).—5. Well-formed crystals of PbS are obtained by passing H_2S into a solution of c. 3 grams $Pb(NO_3)_2$ in 250 c.c. 10 p.c. HNO_3 at c. 15°; if only c. 1 p.c. HNO_3 is present the pp. is amorphous (Muck, Z. [2] 4, 241).—6. Crystalline PbS is produced by the action of PbO on thio-urea (Reynolds, C. J. 45, 162). Addition of H_2S to a Pb salt in presence of $HClAq$ sometimes produces a red pp. of $3PbS.PbCl_2$; on warming and passing in more H_2S , PbS is formed.—7. Winssinger (Bl. [2] 49, 452) obtained an aqueous solution of colloidal PbS by ppg. by H_2S a very dilute solution of a Pb salt, and dialysing; the solution was reddish-brown.

Properties.—Lead-grey crystalline solid, as prepared by fusion of Pb and S ; S.G. 7.505 (Kersten, S. 65, 894). A brown-black powder, as prepared by ppg. by H_2S ; S.G. 6.924 at 4° (Playfair a. Joule, C. J. 1, 137), 6.77 (Schneider, J. pr. [2] 2, 91). Melts at full red-heat out of contact with air, and is said to sublime unchanged. Insol. in dilute acids, caustic alkalis, and alkaline sulphide solutions.

Reactions.—1. Heated in air evolves SO_2 and forms Pb and $PbSO_4$, and some PbO (Descottils, A. Ch. [2] 55, 441).—2. Heated with *lead monoxide* forms Pb and SO_2 ; Pb and SO_2 are also produced by heating with *lead sulphide*; if little PbS is heated with much $PbSO_4$, the chief products are PbO and SO_2 (v. LEAD; Formation, Nos. 1 and 2, p. 122).—3. Melted with scrap iron FeS and Pb are formed.—4. Heated in steam gives H_2S , and at first PbO and afterwards Pb .—5. Heated with alkaline carbonates half the Pb of

the PbS is separated.—6. Boiled with dilute nitric acid $Pb(NO_3)_2$, S , and NO are produced; fuming nitric acid forms $PbSO_4$ and S , and sometimes $Pb(NO_3)_2$.—7. Conc. hydrochloric acid forms $PbCl_2$ and H_2S .—8. *Aqua regia* forms $PbCl_2$ and $PbSO_4$.—9. Slowly reacts with *chlorine* to form $PbCl_2$ and S_2Cl_2 .—10. By long fusion with *potash* and *nitre* Pb_2O_3 is produced (Carnegie, C. N. 60, 113).—11. Heated with lead, subsulphides (q. v.) Pb_2S and Pb_3S are formed.

Combinations.—With *lead chloride* to form the sulphochloride (q. v.) $3PbS.PbCl_2$.

LEAD SUBSULPHIDES. Pb_2S and Pb_3S . Said to be formed by heating together PbS and Pb in the proper proportions (v. Bredberg, P. 17, 274). Pb_2S is also formed, according to Berthier (A. Ch. [2] 22, 240), by heating $PbSO_4$ in a crucible lined with charcoal.

LEAD PERSULPHIDE. Addition of K persulphide to solution of a Pb salt gives a blood-red pp. which is quickly changed, even in the liquid in which it is produced, into PbS and S . Berzelius gives the formula PbS_3 to the persulphide.

Lead, sulphochloride of. $3PbS.PbCl_2$. Obtained as a red pp. by passing a little H_2S into a dilute Pb solution acidified by HCl ; Renisch (J. pr. 13, 130) obtained the compound by passing H_2S into a solution of 1 part Pb acetate in 200 parts water to which 20 parts $HClAq$, S.G. 1.168, were added. Also produced as a yellowish-red solid by digesting freshly-ppd. PbS with $PbCl_2Aq$. Decomposed by H_2S with formation of PbS . Boiling water partly dissolves out $PbCl_2$.

Lead, thiocyanide of. $Pb(SCy)_2$; v. vol. ii. p. 350. Combines with $PbBr_2$ and $PbCl_2$; v. *Lead bromosulphocyanide*, and *Lead chlorosulphocyanide*, pp. 125, 127.

Lead, thiocarbonate of. $PbCS_2$. Formed by adding solution of an alkali thiocarbonate to a Pb salt (cf. THIOCARBONATES, vol. i. p. 703).

M. M. P. M.

LEAD, WHITE. White lead is a hydrocarbonate of Pb varying in composition; v. vol. i. p. 699.

LEAD ORGANIC DERIVATIVES.

Lead trimethyl salts. *Chloride* $PbMe_3Cl$. Formed by the action of boiling aqueous HCl on $PbMe_4$ (Cahours, A. Ch. [3] 62, 257; A. 122, 48). Long needles resembling $PbCl_2$. May be sublimed. M. sol. boiling water and alcohol. Converted into $PbCl_2$ by long boiling with $HClAq$.

Bromide $PbMe_3Br$. More soluble than the chloride.

Iodide $PbMe_3I$. Obtained by adding iodine to $PbMe_4$, till the odour becomes permanent. White mass, crystallising from water in long colourless needles which may be sublimed. Sol. water, v. sol. alcohol. On distillation with solid KOH it yields $PbMe_3OH$, a strong basic oil smelling like oil of mustard solidifying in prisms.

Lead tetra-methyl, $PbMe_4$. (110°) (B.). V.D. 9.52 (calc. 9.25). S.G. 2.034. From MeI and an alloy of lead (5 pts.) and sodium (1 pt.), or, better, from $PbCl_2$ and $ZnMe_2$ (Cahours). Colourless liquid, having a camphor-like odour, insol. water, sol. alcohol and ether (Cahours). According to Butlerow it smells like strawberries or mould. It does not unite directly with chlorine or iodine, but is decomposed thereby. *v. s.*

$\text{PbMe}_2 + \text{I}_2 = \text{PbMe}_2\text{I} + \text{MeI}$. Acids convert it into CH_3 and a salt of PbMe_2 .

Di-plumbic hexa-ethide, Pb_2Et_6 . *Lead triethyl*. S.G. 1.471. Formed by adding sodium (1 pt.) to molten lead (3 pts.) and mixing the cooled and powdered alloy with EtI in flasks provided with inverted condensers. When the first violent action has ceased the product is freed from KI by distilling at 100° , and the residue extracted with ether (Klippel, *J. pr.* 81, 287; cf. Löwig, *J. pr.* 60, 304; A. 88, 318).

Properties.—Yellowish mobile oil, insol. water, v. sol. alcohol and ether. Decomposed on distillation. By exposure to light, or by prolonged boiling with water, it decomposes with separation of metallic lead. When exposed to the air in ethereal solution it absorbs O and CO_2 with formation of $(\text{PbEt}_2)_2\text{O}$ and $(\text{PbEt}_2)_2\text{CO}_2$. It combines with iodine forming PbEt_2I .

Lead triethyl salts. *Chloride* PbEt_2Cl . Obtained by adding BaCl_2 to a solution of $(\text{PbEt}_2)_2\text{SO}_4$ in alcohol, or by treating $(\text{PbEt}_2)_2\text{O}$, $(\text{PbEt}_2)_2\text{CO}_2$, or PbEt_2 with HCl . Beautiful long needles, giving off a pungent odour when heated, presently decomposing with separation of PbCl_2 and metallic lead.— $\text{PbEt}_2\text{HgCl}_2$: white nacreous scales (from hot alcohol).— $(\text{PbEt}_2\text{Cl})_2\text{PbCl}_2$: copper-red crystals, sl. sol. water, m. sol. alcohol and ether.

Bromide PbEt_2Br . Long needles (from ether).

Iodide PbEt_2I . From Pb_2Et_6 and iodine, or from $(\text{PbEt}_2)_2\text{SO}_4$ and KI . Sol. ether and very unstable, the ethereal solution quickly depositing PbI_2 .

Cyanide PbEt_2Cy . From PbEt_2Cl and KCy in alcoholic solution at 100° . Prisms (from ether).

Hydroxide $\text{PbEt}_2(\text{OH})$. From the chloride by treatment with moist Ag_2O or by distillation with KOH . Needles, sl. sol. water, v. sol. alcohol and ether. Has strong alkaline reaction and caustic taste. Saponifies fats; ppts. ferric, cupric, and argentic oxides from their salts. Ppts. alumina and zinc oxide, the pp. dissolving in excess of the precipitant. Expels NH_3 from its salts. Absorbs atmospheric CO_2 . Fumes with HCl . When heated it gives off white vapours which powerfully excite sneezing.

Carbonate $(\text{PbEt}_2)_2\text{CO}_2$. Small hard crystals, nearly insol. water, sl. sol. alcohol and ether. Has a burning taste.

Nitrate PbEt_2NO_3 : unctuous crystalline mass, decomposed by heat with slight detonation. V. sol. alcohol and ether.— $(\text{PbEt}_2)_2\text{SO}_4$: from the oxide and H_2SO_4 . White crystalline pp., nearly insol. water, alcohol, and ether, v. sol. alcohol mixed with H_2SO_4 or HCl , from which solution it separates in octahedra.

Phosphate $(\text{PbEt}_2)_2\text{PO}_4$: stellate groups of crystals, v. sol. water, alcohol, and ether.

Sulphocyanide PbEt_2SCy : crystals, sol. water, alcohol, and ether.

The formate PbEt_2CHO , acetate $\text{PbEt}_2\text{C}_2\text{H}_3\text{O}_2$, butyrate $\text{PbEt}_2\text{C}_4\text{H}_7\text{O}_2$, oxalate $(\text{PbEt}_2)_2\text{C}_2\text{O}_4$, tartarate $\text{PbEt}_2\text{C}_4\text{H}_4\text{O}_6$ (dried at 100°), and benzoate are crystalline.

Lead tetrethide, PbEt_4 . Mol. w. 323 (c. 200°); (152° at 190 mm.) (B.). S.G. 1.62.

Preparation.— PbCl_2 is added to ZnEt_2 , as long as reaction occurs. The PbEt_2 is distilled

with steam. $2\text{ZnEt}_2 + 2\text{PbCl}_2 = 2\text{ZnCl}_2 + 2\text{PbEt}_2$, and then $2\text{PbEt}_2 = \text{Pb} + \text{PbEt}_2$ (Buckton, P. M. [4] 18, 212; 17, 282; A. 109, 218; 112, 220; Frankland & Lawrance, C. J. 35, 244).

Properties.—Oil, not decomposed by water or by gaseous NH_3 , CO_2 , CO , C_2N_2 , NO , O , or H_2S . Partially decomposes at 200° .

Reactions.—1. Gaseous SO_2 reacts forming diethyl sulphone and lead ethyl sulphinate: $\text{PbEt}_2 + 3\text{SO}_2 = \text{Et}_2\text{SO} + (\text{EtSO})_2\text{Pb}$.—2. Iodine forms PbEt_2I and EtI .—3. Conc. HCl forms PbEt_2Cl and ethane.

Di-plumbic hexa-isoamylide, $\text{Pb}_2(\text{C}_5\text{H}_{11})_6$. Prepared like the corresponding Pb_2Et_6 , using isoamyl iodide (Klippel). Oil, with irritating vapour. Detonates with HNO_3 .

Lead tri-isoamyl salts. *Chloride* $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{Cl}$: from the oxide and HCl . White needles.

Iodide $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{I}$: from $\text{Pb}_2(\text{C}_5\text{H}_{11})_6$ in ether by adding iodine. [100°]. Needles, insol. water.— $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{HgI}_2$: golden laminae, insol. water, sl. sol. alcohol and ether.—*Hydroxide* $\text{Pb}(\text{C}_5\text{H}_{11})_3\text{OH}$: viscid mass, insol. water, sol. alcohol and ether. Feebly alkaline, ppts. ferric, but not cupric and silver salts.

Lead tetra-phenyl $\text{Pb}(\text{C}_6\text{H}_5)_4$. [225°]. S.G. 2.1530. Prepared by heating 500 g. of an 8 p.c. alloy of sodium and lead with 500 g. of bromobenzene and 20 c.c. of acetic ether for sixty hours (Polis, B. 20, 716, 3331. Small needles or dimetric prisms; $\alpha_D = 1:381$. Decomposes at 270° . V. sl. sol. alcohol, ether, and HOAc , m. sol. benzene, CHCl_3 , and CS_2 . Heated with HClAq at 230° it yields PbCl_2 , benzene, and chlorobenzene.

Lead diphenyl salts. *Chloride* PbPh_2Cl_2 . Formed by passing chlorine into a solution of lead tetra-phenyl in CS_2 , or by ppg. $\text{PbPh}_2(\text{NO}_3)_2$ with KCl . White powder, insol. alcohol and ether; v. sl. sol. benzene.

Bromide PbPh_2Br_2 . From lead di-phenyl nitrate and KBr . White powder, which decomposes before fusion.

Iodide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{I}_2$. [c. 103°]. Formed by adding iodine to a solution of lead tetraphenyl in chloroform (Polis). Golden plates, sol. chloroform, benzene, and alcohol.

Nitrate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{NO}_3)_2 \cdot 2\text{aq}$. Obtained by gradually adding lead tetra-phenyl to boiling HNO_3 (S.G. 1.4). Small lustrous plates (from water). V. sol. hot water and alcohol. Detonates when heated. Boiling its aqueous solution produces a pp. of the basic salt $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{NO}_3)(\text{OH})$ as a white powder which detonates when heated.

Oxide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{O}$. Obtained by boiling the nitrate with aqueous NaOH (Polis, B. 20, 3832). White powder, insol. alcohol, ether, and benzene.

Oxy-cyanide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{Cy}(\text{OH})$. From the nitrate in aqueous solution and KCy . White powder, insol. water, alcohol, and ether.

Sulphocyanide $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{SCy})_2$. Formed by adding ammonium sulphocyanide to an aqueous solution of the acetate. White powder insol. water and ordinary solvents.

Phosphate $(\text{PbPh}_2)_2(\text{PO}_4)_3$. Formed by adding sodium phosphate to an aqueous solution of the nitrate. White pp., insol. usual solvents.

Oxy-carbonate $(\text{PbPh}_2\text{OH})_2\text{CO}_2$. Ppd. in

a white insoluble powder by adding Na_2CO_3 to solutions of salts of lead diphenyl.

Chromate $\text{Pb}(\text{C}_6\text{H}_5)_2\text{CrO}_4$. From the nitrate and $\text{K}_2\text{Cr}_2\text{O}_7$. Yellow pp., insol. water.

Sulphide $\text{Pb}(\text{C}_6\text{H}_5)_2\text{S}$. From the acetate and H_2S . Yellow prisms, sl. sol. alcohol; v. sol. benzene. Decomposes between 80° and 90° .

Formate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{CHO})_2$, aq. From lead tetra-phenyl and concentrated formic acid. Needles. Melts above 200° , with decomposition.

Acetate $\text{Pb}(\text{C}_6\text{H}_5)_2(\text{C}_2\text{H}_3\text{O}_2)_2$, 2aq. From lead tetra-phenyl and glacial HOAc (Polis, B. 20, 3833). Prisms, v. sol. water containing acetic acid. Melts at 193° when anhydrous.

Lead tetra-p-tolyl $\text{Pb}(\text{C}_6\text{H}_4)_4$. [240°]. S.G. 2.9 1.433. Prepared by heating a mixture of 8 p.c. sodium lead alloy (300 g.), p-bromo-toluene (120 g.), toluene (40 g.), and acetic ether (4 c.c.) for thirty hours in an oil-bath. Repeated crystallisation of the product from benzene and alcohol yields lead tetra-tolyl and di-p-tolyl (A. Polis, B. 21, 3424). Small needles. Decomposes at 254° . More sol. benzene, CS_2 and CHCl_3 than lead tetra-phenyl. When heated with HCl at 200° it gives PbCl_2 and chloro-toluene. Cold conc. HNO_3 causes decomposition with blackening, but on adding lead tetra-tolyl to boiling nitric acid (S.G. 1.4) the products are lead di-tolyl nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{NO}_3)_2$ and nitro-toluene.

Lead di-p-tolyl salts.

Chloride $\text{Pb}(\text{C}_6\text{H}_4)_2\text{Cl}_2$. Formed by passing Cl into a solution of lead tetra-tolyl in CS_2 . White powder, insol. alcohol and ether, sl. sol. CHCl_3 , benzene, and CS_2 . Decomposed when heated. Converted into the corresponding nitrate by AgNO_3 in alcoholic solution.

Bromide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{Br}_2$. From $\text{Pb}(\text{C}_6\text{H}_4)_4$ in CS_2 and bromine. Resembles the chloride.

Iodide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{I}_2$. From $\text{Pb}(\text{C}_6\text{H}_4)_4$ and iodine, both dissolved in CS_2 . Yellow powder, more sol. chloroform and CS_2 than the chloride or bromide.

Nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{NO}_3)_2$, 2aq. Prepared as above. White powder composed of very slender needles; sol. water, containing HNO_3 , sl. sol. alcohol. Detonates when heated.

Oxy-nitrate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{OH})(\text{NO}_3)$. Formed by heating the nitrate with water, or by adding ammonia to a solution of the nitrate in dilute HNO_3 . White amorphous powder.

Chromate $\text{Pb}(\text{C}_6\text{H}_4)_2\text{CrO}_4$. Insol. yellow powder, ppd. by adding $\text{K}_2\text{Cr}_2\text{O}_7$ to a solution of the acetate.

Sulphide $\text{Pb}(\text{C}_6\text{H}_4)_2\text{S}$. Formed by passing H_2S into a solution of the acetate. Transparent yellow plates (from alcohol-benzene), sl. sol. alcohol and ether, v. sol. benzene, CS_2 and CHCl_3 . Begins to turn brown at 90° and melts at 98° . It is decomposed by light.

Formate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{CHO})_2$. Formed from $\text{Pb}(\text{C}_6\text{H}_4)_4$ and formic acid. Beautiful white needles, which at 233° blacken, and decompose.

Acetate $\text{Pb}(\text{C}_6\text{H}_4)_2(\text{C}_2\text{H}_3\text{O}_2)_2$, 2aq. [183.5°]. Formed by adding $\text{Pb}(\text{C}_6\text{H}_4)_4$ to boiling HOAc . Small white needles, more sol. dilute HOAc than the corresponding phenyl compound.

LECANORIC ACID $\text{C}_{12}\text{H}_{18}\text{O}_7$. (a)-*Orsellic acid*. *Diorcellic acid*. [153° cor.]. S. .04 at

100° (Schunck). S. (80 p.c. alcohol) .7 at 15° (Schunck), S. (ether) .4 at 20° (Hesse); 1.25 at 15° (Schunck). Discovered by Schunck in 1842 and extracted from several lichens of the genera *Lecanora*, *Variolaria*, and *Roccella* (Schunck, A. 41, 157; 54, 261; 61, 72; Roehleder, A. Heldt, A. 43, 1; Stenhouse, A. 68, 61; 70, 218; Strecker, A. 68, 108; Laurent a. Gerhardt, A. Ch. [3] 24, 315; Robiquet, A. Ch. 42, 236; Hesse, A. 139, 22). Obtained by exhausting the lichens with ether, dissolving the greenish-white crystalline residue left on evaporation in milk of lime, pp. the filtrate with H_2SO_4 , washing the pp. with water, and recrystallising it from hot alcohol (Hesse). Stellate needles (containing aq.). Almost insol. cold water. Decomposed by heat with evolution of CO_2 . A solution of barium lecanorate is not decomposed by CO_2 . FeCl_3 colours its alcoholic solution dark purple-red. An ammoniacal solution of lecanoric acid forms white pps. with lead subacetate and with AgNO_3 , but the silver salt is quickly reduced. An alcoholic solution gives no pp. with alcoholic solutions of lead acetate, HgCl_2 , or AgNO_3 , but with cupric acetate it gives an apple-green pp. When a solution of lecanoric acid is boiled it gives orsellic acid $\text{C}_{12}\text{H}_{14}\text{O}_7 + \text{H}_2\text{O} = 2\text{C}_6\text{H}_8\text{O}_7$. A solution of barium lecanorate yields, on boiling, first barium orsellate, and finally orcin $\text{C}_8\text{H}_8\text{O}_4$ and BaCO_3 . An alcoholic solution yields, on boiling, orsellic ether. An ammoniacal solution acquires, on exposure to air, a splendid purple colour, through formation of orcein. Bleaching-powder gives a red tint, quickly changing to brown.

Salt.—*BAA*: small stellate needles.

Di-bromo-lecanoric acid $\text{C}_{12}\text{H}_{12}\text{Br}_2\text{O}_7$. [179°]. From lecanoric acid and Br in ether (Hesse). White crystals (from alcohol), insol. water. FeCl_3 colours its alcoholic solution violet. Gives off CO_2 on fusion.

Tetra-bromo-lecanoric acid $\text{C}_{12}\text{H}_8\text{Br}_4\text{O}_7$. [157°]. From lecanoric acid and excess of Br in ether. Pale yellow prisms (from alcohol), v. sol. alcohol, ether, and alkalis. FeCl_3 colours its alcoholic solution purple. Boiling baryta-water decomposes it.

LECITHIN $\text{C}_{44}\text{H}_{88}\text{O}_8\text{PN}$ (Von Lippmann, B. 20, 3201; $\text{C}_{41}\text{H}_{80}\text{O}_8\text{PN}$ (Diaconoff). *Protagon*. Occurs in the eggs and milt or soft roe of the carp and herring, the yolk of poultry eggs, the brain of man, sheep, and domestic fowl, bile of pigs, men, and oxen, retina of oxen, blood, yeast, milk, butter, radicles of sprouting lupin seeds, maize, peas, wheat, beet-root, &c. (Gobley, J. Ph. [3] 9, 1, 83, 161; 11, 409; 12, 5; 17, 401; 18, 107; 19, 406; 21, 241; 80, 241; 83, 161; Strecker, A. 123, 356; Z. [2] 4, 437; Kodweiss, A. 59, 261; Diaconoff, Z. [2] 4, 154; Liebreich, A. 134, 29; Cahn, H. 5, 215; Hoppe-Seyler, Z. 2, 427; 3, 378; J. 1866, 698, 744; Hermann, Z. 1866, 250; Schmidt-Mülheim, J. Th. 1883, 166; Schulze a. Barbieri, J. p. [2] 27, 858; H. 13, 865; Hækel a. Schlagdenhauffen, C. R. 103, 388; Copeman a. Winston, J. Physiol. 10, 213).

Preparation.—1. Yolk of egg is extracted with alcohol-ether, and an alcoholic solution of platonic chloride is added. A compound of lecithin and platonic chloride is ppd., and this is agitated with Ag_2O , the filtrate freed from silver by H_2S and evaporated (Strecker).—2. Brain is

exhausted with ether, and the residue extracted with absolute alcohol at 40°. The alcoholic extract is cooled at 0° and filtered, and the pp. of lecithin and cerebrin collected, washed with alcohol, and treated with ether. The ethereal solution of lecithin is evaporated (Diaconoff).—8. Beet-root is extracted with ether-alcohol, the ether evaporated and the residue dissolved in alcohol and ppd. by platinic chloride. The pp. is decomposed by H_2S (Lippmann).

Properties.—Hygroscopic wax-like substance, which swells up in water and is v. sol. alcohol, ether, chloroform, and oils. Boiling with baryta-water produces glycerol-phosphoric acid, neurine, and a fatty acid (stearic, oleic, or palmitic). According to Diaconoff lecithin from brain may be separated by dissolving in alcohol and cooling to -10° , into a stearo-lecithin which separates and an oleo-lecithin which remains in solution. According to Strecker the decomposition by baryta may be represented thus:—

or
 $C_{2n+3}H_{10+18}O_2NP + 3H_2O = \\ 2C_nH_{2n}O_2 + C_3H_7PO_4 + C_3H_7NO;$
 thus stearo-lecithin would be $C_{44}H_{86}O_2NP$, while oleo-lecithin would be $C_{44}H_{86}O_2NP$ and might be written

$(C_{18}H_{34}O_2)_2C_2H_5O.PO(OH).O.C_3H_7.N(CH_3)_3.OH$. The particular lecithin examined by Strecker appeared, however, to be $C_{42}H_{82}O_2NP$ or to contain one oleyl and one palmityl radicle in place of the two oleyls in the above formula. That the neurine is not present as a base appears from the observation that lecithin is hardly attacked by dilute (10 p.c.) sulphuric acid (Gilson, *H.* 12, 585). The neurine salt of di-stearyl-glycerol-phosphoric acid appears therefore not to be a true lecithin (v. GLYCERIN). According to Lippmann the base obtained by boiling beet-root lecithin with baryta is sometimes neurine and sometimes betaine. The presence of lecithin enables a solution of glucose to absorb oxygen from the air in the same way as an alkaline solution of that sugar (Nencki a. Sieber, *J. pr.* [2] 26, 17).

Salts.—The hydrochloride is a waxy mass. $(C_{44}H_{86}O_2PN)_2PtCl_4$: yellow flocculent pp. v. sol. ether, chloroform, and benzene, but ppd. from these solutions by alcohol (Strecker).— $CdCl_2$ gives a pp. in a solution of lecithin in ether-alcohol.

LEDITANNIC ACID $C_{11}H_{20}O_8$. Occurs in the leaves of the marsh wild rosemary (*Ledum palustre*) (Willigk, *A.* 74, 363; Roehleder a. Schwartz, *A.* 74, 366; *Z.* 1866, 382; Thal, *J.* 1893, 1401). Prepared by ppg. the alcoholic decoction of the leaves with water, and the filtrate with lead acetate. The pp. is dissolved in dilute HOAc, filtered, heated to boiling, and ppd. with lead subacetate. The pp. is suspended in water and decomposed by H_2S , and the filtrate evaporated in a current of CO_2 . Reddish powder, v. sol. water and alcohol. $FeCl_3$ colours its aqueous solution dark green. Lead acetate and $SnCl_4$ give yellow pps. Boiling dilute H_2SO_4 forms ledixanthin but no sugar.

Ledixanthin $C_8H_{16}O_4$ is a reddish-yellow powder, v. sol. alkalis. Its alcoholic solution

gives a reddish-brown pp. with lead acetate. On dry distillation it yields pyrocatechin.

LEDUM OIL. An oil obtained by steam distillation from the leaves of *ledum palustre*. According to Willigk (*Sitz. W.* 9, 302) it consists of a terpene and of an oxygenated oil $C_{20}H_{34}O_2$. Grassmann (*Rep. Pharm.* 88, 53) obtained a volatile oil (1 pt.) and ledum-camphor (2 pts.). Fröhde (*J. pr.* 82, 181) found the oil to be acid and to contain a terpene (160°) and an oxygenated oil (241°). According to Trapp (*Russ. Zeit. Pharm.* 1874, 289) the oil when recently prepared is yellowish, viscid, lighter than water, and possesses a pungent odour; when exposed to air the greater part solidifies to a crystalline mass soluble in alcohol. The solution of this solidified oil (ledum camphor) in H_2SO_4 is turned violet by HNO_3 . Ivanoff (*Russ. Zeit. Pharm.* 1876, 577) found ledum oil to consist of a white crystalline mass saturated with oil. By repeated crystallisation from alcohol white prisms of $C_{15}H_{26}O_2$ were obtained. These were insol. water, v. sol. alcohol, ether, chloroform, and benzene, melted at 101° , boiled at 174° , and were dextrorotatory in alcoholic solution. According to Hjelt a. Collan (*B.* 15, 2500) ledum camphor melts at 101° , and has a vapour density 12.33 corresponding with the formula $C_{20}H_{34}O_2$ (calc., 13.02), and sublimes in long white needles. Rizza (*J. R.* 19, 319) gives the following properties for ledum camphor, $C_{15}H_{26}O$ [101°]; (292° i. v.); V.D. 8.10; and states that Ac_2O at 160° converts it into a sesquiterpene $C_{15}H_{24}$ (264°), S.G. 2.935.

LEGUMIN v. PROTEIDS.

LEKENE C_2H_4 . [79°]. S.G. = .939. Forms the chief constituent of ozokerit or mineral wax, from which it is isolated by distilling the wax *in vacuo*, dissolving the distillate in benzene, and precipitating with absolute alcohol (Beilstein a. Wiegand, *B.* 16, 1547). White glistening crystals. S. (90 p.c. alcohol at 16°) = .0105; S. (benzene at 15°) = .8; sparingly sol. in most other cold solvents, e. sol. hot benzene and chloroform, insol. acetone. It decomposes on distillation under ordinary pressure, but can be distilled *in vacuo*. It is very stable towards oxidising agents.

LEMON OIL. Obtained by pressure from the peel of the fruit of *citrus medica*. Contains a terpene $C_{10}H_{16}$ (166°) (Blanchet a. Sell, *A.* 6, 281; Soubeiran a. Capitaine, *A.* 34, 317) or (175°) (Regnault, *J.* 1863, 70; *A.* 52, 171). S.G. .85 at 15° – 22° . The terpene is dextrorotatory, $[\alpha]_D = 109^\circ$ (Kanonnikoff, *Bn.* 3, 299). According to Wallach (*A.* 227, 296) oil of lemon contains pinene and hesperidene (cf. Deville, *A.* 71, 348; Oppenheim, *B.* 5, 628). In examining the essential oil obtained by steam distillation from lemon peel, Tilden (*Ph.* [3] 9, 664) found the S.G. to be .853 at 20° , and the rotation + 59° in a column 100 mm. long. In this oil he found terbenzene $C_{10}H_{16}$, citrene $C_{10}H_{16}$ (constituting 70 p.c. of the whole), gymene (6 p.c.), a dextrorotatory body $C_{10}H_{16}O$ resembling terpineol (over 200°), a compound ether $C_{10}H_{16}O$ decomposed by heat into HOAc and C_9H_{14} , and $C_9H_{14}O$ [116°] Tilden a. Dick, *C. J.* 57, 32). The citrene (178°) forms a terpene hydrate when treated with HNO_3 . $CoCl_2.H_2SO_4$ converts it into an inactive hydrocarbon (178°). Bouchardat a. Lafont (*C. R.* 101, 883) find in essence of lemon a terpene $C_{10}H_{16}$ (178°) with a rotatory power + 105° which yields

(*v. supra*). Sodium amalgam, acting on the acetic acid solution, reduces it to hydro-oxylepiden $C_{22}H_{22}O_2$ (Zinin). When heated with benzoin it is reduced to lepiden, whilst the benzoin yields benzil (Limpricht & Schwanert, B. 4, 338). Alcoholic ammonia at 200° converts it into a mixture of two imides of the formula $C_{22}H_{21}NO$ —one derived from 'acicular,' the other from 'tabular,' oxylepiden—whilst with methylamine it yields a methylimide $C_{22}H_{22}NO$ [161°] (Klingemann & Laycock, *private communication*). Heating with phosphorus pentachloride converts it into dichlorolepiden.

C. S. Pr. 1889, 137). By heating 'acicular oxylepiden' to 340° and recrystallising the product, first from ether and afterwards from alcohol. Tabular crystals are deposited first, then microscopic octahedral of the third modification (Zinin, J. R. 5, 10). Tabular crystals [136°], insol. water, sol. 14.5 pts. boiling alcohol (95 p.c.), and in its own weight of boiling glacial acetic acid. Dissolves readily in hot alcoholic potash solution (distinction from 'octahedral oxylepiden'), forming a salt of oxylepidenic acid $C_{22}H_{21}O_2$ (*infra*). Zinc and acetic acid are without action on it; but sodium and boiling amyl alcohol reduce it to tetraphenylbutyrolactone $C_{22}H_{22}O_2$. Alcoholic ammonia at 200° converts it into an imide $C_{22}H_{21}NO$; with alcoholic methylamine at 150° it yields the methylimide of oxylepidenic acid $C_{22}H_{22}O_2(NHCH_3)$. When heated with phosphorus pentachloride at 200° it forms chloroxylepiden $C_{22}H_{21}ClO_2$.

3. 'Octahedral oxylepiden.' Only 2 p.c. of this compound is formed when 'acicular oxylepiden' is heated to 340° . Most readily obtained by boiling 'acicular oxylepiden' with an alcoholic solution of caustic potash or caustic soda. Four parts of 'acicular oxylepiden' are boiled for 12–15 hours with 60 parts of alcohol (95 p.c.) and 3 parts of caustic soda, employing a reflux condenser. The product is washed successively with alcohol, water, and ether, and is finally recrystallised from boiling acetic acid (Zinin, J. R. 7, 186; J. 1875, 409).—Yellowish, microscopic octahedra [232°]. Sol. 76 parts boiling glacial acetic acid, almost insol. alcohol. When heated to incipient boiling it is totally converted into 'tabular oxylepiden.' Boiling the acetic acid solution with zinc reduces it to hydro-oxylepiden, part of which loses water, yielding lepiden. A solution of chromic anhydride in acetic acid oxidises it to isodioxyepiden $C_{22}H_{20}O_2$. Alcoholic potash is without action on it.

As regards the constitution of 'octahedral oxylepiden,' it is probable that this compound is a stereometric isomeride of 'acicular oxylepiden,' the latter representing the *maleoid*, the former the *fumaroid* form of dibenzoyl-stilbene:

(Japp & Klingemann, C. S. Pr. 1889, 138). Both yield on reduction the same hydro-oxylepiden (bidesyl)

which may be converted by dehydration into lepiden.

The three oxylepidens yield by destructive distillation the same so-called *isolepiden* $C_{22}H_{20}O$ (*infra*).

Chloroxylepiden $C_{22}H_{21}ClO_2$. By heating 'tabular oxylepiden' with a mixture of phosphorus pentachloride (1 part) and phosphorus trichloride ($\frac{1}{2}$ part) at 180° – 200° (Zinin, J. R. 5, 21.—Crystals [185°]; sol. 22.8 parts boiling glacial acetic acid.

Dichloroxylepiden $C_{22}H_{21}Cl_2O_2$. 'Acicular dichloroxylepiden' is obtained by heating lepiden with four times its weight of phosphorus pentachloride and treating the product with water (Zinin, J. R. 5, 23). By the oxidation of dichlorolepiden [169°] (Zinin, J. R. 7, 332; J. 1876, 426).—Needles [202°]; sol. 146 parts cold, 13.7 parts boiling acetic acid, 90 parts boiling ether. When boiled with zinc and acetic acid it yields a mixture of hydrodichloroxylepiden and isodichlorolepiden [166°].

When the foregoing 'acicular dichloroxylepiden' is heated to near its boiling-point it is converted into a mixture of two new isomeric dichloroxylepidens, which may be separated by the difference in their solubility in ether. 'Readily soluble dichloroxylepiden,' which forms the chief product, is very soluble in alcohol, ether, and acetic acid, and is deposited from these solutions as a soft resin. Alcoholic caustic potash converts it into a salt of dichloroxylepidenic acid $C_{22}H_{20}Cl_2O_2$. The other isomeride, 'sparingly soluble dichloroxylepiden,' is best prepared by boiling 4 parts of 'acicular dichloroxylepiden' with three parts of caustic soda and 40 parts of alcohol for from 20 to 24 hours. It forms a granular powder consisting of microscopic prisms [230°]; almost insol. alcohol and ether, sol. 36 parts boiling glacial acetic acid. Boiling with acetic acid and zinc converts it into isodichlorolepiden [166°] (Zinin, J. R. 7, 191).

These three compounds, as their mode of formation and reactions denote, are to be regarded as dichloro-substitution products of 'acicular,' 'tabular,' and 'octahedral' oxylepiden respectively.

• A fourth *dichloroxylepiden* has been obtained by Dorn (A. 153, 353) by treating *dichlorophenyl* $C_{22}H_{21}Cl_2$ with hydrochloric acid and potassium chlorate.—Small needles [178°]; readily sol. alcohol, benzene, and glacial acetic acid. Not attacked by alcoholic potash at 150° . Zinc and acetic acid convert it into a dichlorolepiden [166°] (*v. supra*); whilst with hydriodic acid at 100° it yields dichlorolepiden, lepiden, and oxylepiden (?).

• Dibromoxylepiden $C_{22}H_{21}Br_2O_2$. Three dibromoxylepidens, corresponding with the first three of the foregoing dichloroxylepidens, have also been described by Zinin (J. R. 7, 329; J. 1876, 425). In their modes of preparation, properties, and reactions, they resemble the chlorine compounds. 'Acicular dibromoxylepiden' is obtained either by brominating 'acicular oxylepi-

den' or by oxidising dibromoxylepiden in acetic acid solution with nitric acid. Needles [222°]; sol. 40 parts boiling acetic acid. Heated above its melting-point it yields two isomeric dibromoxylepidens—'readily soluble dibromoxylepiden,' which is resinous, v. sol. alcohol, ether, and acetic acid, and is converted by alcoholic caustic potash into a salt of dibromoxylepidenic acid $C_{28}H_{20}Br_2O_2$, and 'sparingly soluble dibromoxylepiden.' This latter is more easily obtained by boiling the acicular modification with a quantity of alcoholic potash insufficient to dissolve it. Crystallises from alcohol in lemon-yellow rhombic tables [239°]; almost insol. ether, sol. 66 parts boiling acetic acid and 1,000 parts boiling alcohol (95 p.c.). Heated above its melting-point it is converted into 'readily soluble dibromoxylepiden' (Zinin, *J. R.* 7, 329; *J.* 1876, 425).

Both 'acicular' and 'sparingly soluble' dibromoxylepiden, when reduced with zinc and acetic acid, yield the same hydrodibromoxylepiden (dibromobidesyl), part of which undergoes dehydration, forming dibromolepiden [190°].

Hydro-oxylepiden (*Bidesyl*)

Formed, along with lepiden, by the action of zinc and acetic acid on 'octahedral oxylepiden,' or of sodium amalgam on 'acicular oxylepiden.' The product of the reaction is pptd. with water and treated with ether, which dissolves only the lepiden (Zinin, *J. R.* 7, 188; *J.* 1875, 409). By the action of desyl bromide, $C_6H_5 \cdot CHBr \cdot CO \cdot C_6H_5$, on sodium-deoxybenzoin, or of iodine on sodium-deoxybenzoin:

(Knövenagel, *B.* 21, 1358).—Long flat needles (from acetic acid); [251°] (Zinin); [254°-255°] (Knövenagel; also Magnanini a. Angeli). Almost insol. cold alcohol and ether, sol. 112 pts. boiling acetic acid, sol. hot benzene. Heated with hydrochloric acid at 130°-140° it parts with water, yielding lepiden (Magnanini a. Angeli, *B.* 22, 855).

Tetraphenylbutyrolactone

By treating a solution of 'tabular oxylepidene' (tetraphenylbutyrolactone) in boiling amyl alcohol with sodium (Klingemann a. Laycock, *private communication*).—Microscopic, white needles [221°], sol. boiling, sl. sol. cold, alcohol.

Hydrodichloroxylepiden $C_{28}H_{20}Cl_2O_2$. Formed, along with dichlorolepiden, when 'sparingly soluble dichloroxylepiden' is boiled for a long time with zinc and acetic acid, or, more readily, by boiling an alcoholic solution of 'acicular dichloroxylepiden' with sodium amalgam, keeping the liquid acid with acetic acid (Zinin, *J. R.* 7, 195; *J.* 1875, 413).—Flat needles (from acetic acid) [261°], insol. alcohol and ether, sol. 205 pts. boiling acetic acid.

Hydrodibromoxylepiden $C_{28}H_{20}Br_2O_2$. By the action of zinc and acetic acid on 'acicular' or 'sparingly soluble' dibromoxylepiden (Zinin,

J. R. 7, 830; *J.* 1876, 425).—Slender needles, v. sl. sol. alcohol and ether, sol. 172 pts. boiling acetic acid.

Dioxylepiden $C_{28}H_{20}O_2$. By warming 25 pts. of 'acicular oxylepiden' suspended in 20 pts. of acetic acid, with a solution of 12-15 pts. of chromic anhydride dissolved in 150 pts. of acetic acid (Zinin, *Z.* 1871, 483).—Rhombic tables [157°], sol. 24 pts. boiling alcohol (95°). Reducing agents are without action on it. By further action of chromic anhydride it yields benzil and benzoic acid. Alcoholic potash hydrolyses it into deoxybenzoin and benzoic acid:

Isodioxylepiden $C_{28}H_{20}O_2$. By boiling 'octahedral oxylepiden' with a solution of chromic anhydride in acetic acid (Zinin, *J. R.* 7, 190; *J.* 1875, 410).—Laminae [164°], sol. 10 pts. boiling alcohol, less sol. ether, sol. 4 pts. boiling acetic acid. Boiling alcoholic potash is without action on it (distinction from foregoing isomeric).

Oxylepidenimide $C_{28}H_{21}NO$. By heating 'acicular oxylepiden' with alcoholic ammonia for 5 hours at 200°; it yields a mixture of oxylepidenimide and the isomeric tetraphenylpyrrholone. The oxylepidenimide is separated by means of its greater solubility in alcohol (Klingemann a. Laycock, *private communication*).—Yellow prisms (from benzene) [180°-182°]. Heated to 310° it changes into tetraphenylpyrrholone (*v. infra*).

Oxylepiden-methylimide $C_{28}H_{29}O(N \cdot CH_3)$. By heating 'acicular oxylepiden' with an alcoholic solution of methylamine for 2 hours at 200° (K. a. L.).—Small pale-yellow plates [161°] from alcohol; well-shaped crystals from carbon bisulphide. V. sol. benzene, readily sol. carbon bisulphide, moderately sol. boiling alcohol.

Oxylepidenic acid (*Benzoyl-triphenyl-pro-*

(Japp a. Klingemann, *C. S. Pr.* 1889, 135). The potassium salt is formed when 'tabular oxylepiden' is dissolved in hot alcoholic potash (Zinin, *J. R.* 5, 18).—The acid crystallises in laminae, v. sol. ether, sol. 3.5 pts. boiling alcohol (95 p.c.), insol. water. Melts at 196°, breaking up into 'tabular oxylepiden' and water:

The so-called *isoxylepidenic acid* described by Zinin (*J.* 1877, 397) is identical with the foregoing (Japp a. Klingemann, *C. S. Pr.* 1889, 139).

Tetraphenylpyrrholone

with the isomeric oxylepidenimide, when 'acicular oxylepiden' is heated with alcoholic ammonia at 200°. By heating oxylepidenimide to 310°. As sole product when 'tabular oxylepiden' is heated with alcoholic ammonia at 200° (Klingemann a. Laycock).—Small pale-yellow plates [208°], sparingly sol. alcohol.

formed appears to be isomeric, not identical, with oxy-lepiden-methylimide (K. a. L.).

Dichloroxy-lepidenic acid $C_{22}H_{29}Cl_2O_2$. By dissolving 'readily soluble dichloroxy-lepiden' in boiling alcoholic potash (Zinin, *J. R.* 7, 191; *J.* 1875, 411).—Rhombic laminae [182°], from acetic acid. Sol. 16 pts. boiling acetic acid. Heated to 200° it parts with 1 mol. water, and is reconverted into 'readily soluble dichloroxy-lepiden.'

Dibromoxy-lepidenic acid $C_{22}H_{29}Br_2O_2$. By dissolving 'readily soluble dibromoxy-lepiden' in boiling alcoholic potash (Zinin, *J. R.* 7, 330; *J.* 1876, 425).—Six-sided laminae from acetic acid.

So-called isolepiden and its derivatives.

Under the name of *isolepiden*, Zinin (*J. R.* 5, 20) has described a compound which he obtained by the destructive distillation of oxy-lepiden, and which he regarded as isomeric with lepiden. Japp a. Klingemann have, however, shown (*C. S. Pr.* 1889, 139) that this compound has the formula $C_{27}H_{35}O$, instead of $C_{22}H_{29}O$, and that it is formed from oxy-lepiden with elimination of carbonic oxide according to the equation $C_{22}H_{29}O_2 = C_{27}H_{35}O + CO$.

The name 'isolepiden' is consequently inappropriate, but will be retained here, as the constitution of the compound is unknown, and a systematic name cannot be given. The formulae of the various hydro- 'isolepidens' and oxy- 'isolepidens' described by Zinin must also be written with 27 instead of with 28 atoms of carbon, although these compounds have not yet been re-investigated.

Isolepiden $C_{27}H_{35}O$ (Japp a. Klingemann, *l.c.*). By the destructive distillation of oxy-lepiden (Zinin, *J. R.* 5, 20; cf. preceding paragraph). The three oxy-lepidens all yield this compound on distillation; but in reality it is only 'tabular oxy-lepiden' which yields it, as the other two oxy-lepidens are previously transformed into 'tabular oxy-lepiden' at the temperature of the reaction. The distillate is washed with ether and then recrystallised, first from alcoholic potash, afterwards from alcohol. The ether extracts a little 'tabular oxy-lepiden,' which is carried over undecomposed (Japp a. Klingemann, *C. S. Pr.* 1889, 139).—Isolepiden forms yellow tabular crystals [150°]. Decomposes on redistillation. Sol. 18 pts. boiling alcohol (95 p.c.), and in 2 pts. boiling acetic acid (Zinin, *J.* 1877,

394). Not attacked by alcoholic potash. It is reduced by zinc-dust and acetic acid to dihydro-isolepiden $C_{27}H_{37}O$, and by sodium amalgam to tetrahydro-isolepiden $C_{27}H_{39}O$. Oxidising agents convert it into oxy-isolepiden, and ultimately into a mixture of benzophenone and benzil.

Dihydro-isolepiden $C_{27}H_{37}O$. By reducing a solution of isolepiden in from 5 to 6 pts. of acetic acid with zinc-dust. The product is poured into water, and the pp. is washed with ether and recrystallised from alcohol (Zinin, *J.* 1877, 394).—Small rectangular prisms [182°]. Sol. 12.5 pts. boiling alcohol (95 p.c.), v. sl. sol. ether.

Tetrahydro-isolepiden $C_{27}H_{39}O$. By the action of sodium amalgam on a boiling alcoholic solution of isolepiden (Zinin). Separates from ether as a soft resinous mass which soon becomes crystalline [182°]. Readily sol. alcohol and acetic acid, less sol. ether. Chromic anhydride oxidises it in acetic acid solution, even in the cold, to dihydro-isolepiden.

Oxyisolepiden $C_{27}H_{35}O_2$. Three pts. of isolepiden are dissolved in 40 pts. of acetic acid, and oxidised with a solution of 3 pts. of chromic anhydride in 30 pts. of acetic acid (Zinin, *J.* 1877, 395).—Short slender needles [161°]. Sol. 40 pts. boiling, and 600 pts. cold alcohol, and in 4 pts. boiling acetic acid. Boiling alcoholic potash is without action on it. Zinc and acetic acid reduce it to dihydro-isolepiden. Excess of chromic acid oxidises it, in acetic acid solution, to benzophenone as chief product, together with benzil and benzoic acid.

Oxy-isolepiden, like oxy-lepiden, may be converted into isomeric compounds. Thus, when it is boiled with a quantity of alcohol or alcoholic potash insufficient to dissolve it, it is transformed into *cuneiform oxy-isolepiden* [162°]. When this is heated above its melting-point, or when ordinary oxy-isolepiden is distilled, *tabular oxy-isolepiden*, a third isomeride, is formed. Rhombic tables [152.6°] from acetic acid. Sol. 13.5 pts. boiling acetic acid, 80 pts. boiling alcohol. F. R. J.

LEPIDINE v. (Py. 1)-METHYL-QUINOLINE.

LEUCANILINE is described under **TRI-AMIDO-DI-PHENYL-TOLYL-METHANE**.

Para-leucaniline is described as **TRI-AMIDO-TRI-PHENYL-METHANE**.

LEUCAURIN v. TRI-OXY-TRI-PHENYL-METHANE.

LEUCATROPIC ACID $C_{17}H_{25}O_4$. [74°]. Occurs in belladonna (Kunz, *Ar. Ph.* [3] 23, 722). Minute satiny needles. Insol. cold, m. sol. boiling water, and alcohol.

LEUCINES v. PROTEIDS.

LEUCIC ACID. Described as **OXY-HEXOIC ACID**.

LEUCINDIGO v. INDIGO.

LEUCINE $C_6H_7NO_2$ i.e.

$CH_3.CH_2.CH_2.CH_2.CH(NH_2).CO_2H$. *α-Amido-n-hexoic acid*. Mol. w. 131. [170°] (Schwanert). S.G. 1.298 (Engel a. Vilmain, *Bt.* [2] 24, 279). S. 2.2 at 18° (Schulze, *M.* 9, 254); 8.7 in the cold (Zollkofer). S. (alcohol of S.G. 828) 152 in the cold (Mulder). S. (96 p.c. alcohol) 096 in the cold (K.). S. (98 p.c. hot alcohol) 125 (K_p). $[\alpha]_D^{20} = +14.1^\circ$ in a 15 p.c. HCl solution; $= +5.6^\circ$ in a 25 p.c. solution in NH_4Aq (Reese, *A.* 242, 11). Discovered by Moutst (*A. Ch.* [3] 10, 40) as a product of the putrefaction of cheese, and called 'caseous oxide.' Braconnot

(*A. Ch.* [2] 18, 119) found it among the products of the action of H_2SO_4 on animal substances. Mulder (*J. pr.* 16, 290) showed the two substances thus obtained were identical.

Occurrence.—In old cheese (Proust), in fresh calf's liver (Liebig, *Chem. Briefe*, ed. 3, 453), in diseased but not in healthy human liver (Frerichs & Städeler, *J.* 1854, 675; 1856, 702; 1858, 550), in the tissue of the lungs (Cloetta, *A.* 92, 289), in the thymoid and thyroid glands, and in the pancreas (Gorup-Besanez, *A.* 98, 7; Kadziejewsky, *Z.* 1866, 416), in the brain of oxen (W. Müller, *A.* 103, 131), in the pancreas of oxen (Scherer, *J.* 1859, 610), in the liver and urine in cases of typhus, smallpox, leucæmia, and poisoning by phosphorus (Salkowsky, *J. Th.* 1880, 457; Valentiner, *J.* 1854, 675; Sotnitschewsky, *H.* 3, 391), in the stomachs and intestines of the pupæ of butterflies (Schwarzenbach, *J.* 1857, 538), in *Agaricus muscarius* (Ludwig, *J.* 1862, 316), in the juice of vetches germinated in the dark (Gorup-Besanez, *B.* 7, 146; cf. Cossa, *G.* 5, 314), in *chenopodium album* in young pumpkin plants (Schulze & Barbieri, *B.* 11, 1233), and in beet-root molasses (Lippmann, *B.* 17, 2837).

Formation.—1. In the putrefaction of proteids and gelatin (Beyl, *A.* 69, 20) and by boiling these substances with dilute H_2SO_4 , or by fusing them with potash (Hinterberger, *Sitz. W.* 9, 450; *A.* 71, 75; Zollikofer, *A.* 82, 174; Gossmann, *A.* 91, 130; Leyer & Köller, *A.* 83, 332; Schlossberger, *Z.* 1860, 424; Erlenmeyer & Schäffer, *Z.* 1859, 315; Hochstetter, *J. pr.* 29, 36; Ritt-hausen & Kreisler, *J. pr.* [2] 3, 307).—2. In the pancreatic digestion of gelatin (Nencki, *B.* 7, 1593; Jeanneret, *J. pr.* [2] 15, 353).—3. By acting on α -bromo-hexoic acid with ammonia (Hüfner, *J. pr.* [2] 1, 6; *Z.* [2] 4, 391, 616).

Preparation.—Horn shavings (2 lbs.) are boiled with H_2SO_4 (5 lbs.) and water (13 lbs.) for 24 hours with inverted condenser. The product is mixed with lime, filtered, and evaporated to a smaller bulk (12 lbs.). Oxalic acid is then added to acid reaction, and the liquid filtered and evaporated till a crystalline film forms on the surface. Leucine mixed with tyrosine is deposited in groups of yellowish laminae. On recrystallisation from water tyrosine is deposited first, and the mother-liquor is then decolourised by animal charcoal and evaporated. The leucine is recrystallised from alcohol (Schwanert, *A.* 102, 221; cf. Hinterberger, *A.* 71, 72; Waage, *A.* 118, 297). Leucine may be detected and isolated by means of its sparingly soluble copper salt $(C_6H_{11}NO)_2Cu$, although the precipitation of this salt is hindered by free acids and by some organic bodies (Hoffmeister, *Sitz. W.* 75, 469).

Properties.—Soft nacreous scales (from alcohol) resembling cholesterol. It may be sublimed (Mulder). Decomposed on fusion, giving amylinine, CO_2 , and NH_3 . Lævorotatory (Low-kovitch, *B.* 17, 1439; cf. Mauthner, *H.* 7, 223). Sl. sol. water and alcohol, insol. ether. Its solubility in water is increased by the presence of acetic acid or an alkaline acetate. When heated with baryta-water at 160° it becomes inactive. The inactive leucine is changed to an active variety, lævorotatory when dissolved in aqueous HCl, by the action of *Penicillium glaucum* (Schulze & Bosshard, *B.* 18, 888).

Reactions.—1. Heated, yields CO_2 , butyric acid, and NH_3 (Gorup-Besanez, *A.* 125, 210).—2. Chlorine passed into water in which leucine is suspended forms CO_2 and valerionitrile, as well as chloro-valerionitrile (Schwanert). Chlorine passed into an alkaline solution of leucine forms oxy-hexoic acid.—3. Nitrous acid converts it into α -oxy-hexoic (leucic) acid.—4. Distillation with MnO_2 and dilute H_2SO_4 yields CO_2 and valerionitrile.—5. Distillation with water and PbO yields butyric aldehyde and NH_3 (Liebig, *A.* 70, 313).—6. Aqueous $KMnO_4$ yields NH_3 , oxalic acid, and valeric acid (Neubauer, *A.* 106, 59).—7. Potash-fusion gives NH_3 , hydrogen, and potassium valerate (Liebig, *A.* 57, 127).—8. When heated with fuming HNO_3 at 140° it gives hexoic acid and ammonia (Hüfner).—9. With KOH (2 mols.) and MeI (3 mols.) it forms potassium di-methyl-amido-hexoate methyl-iodide $C_6H_{10}(NMe_2)_2CO_2K$, which, when heated with moist Ag_2O , yields methylamine, a salt $C_6H_{10}O_2K$, and potassium leuconate $C_6H_{10}O_2K$ (Körner & Menozzi, *G.* 13, 353).—10. Leucine gives off more nitrogen when its solution is decomposed by $NaBrO$ in presence of NH_3 , than when the NH_3 is absent (F. Schulze, *J. pr.* [2] 31, 236).

Salts.— $HA \cdot HCl$: crystals, v. sol. water (Laurent & Gerhardt, *A. Ch.* [3] 24, 321; *A.* 63, 365).— $(HA)_2 \cdot HCl$: laminae (Schwanert).— $(HA)_2 \cdot H_2PtCl_6$: yellow crystalline pp.— $HA \cdot HNO_3$: colourless needles, v. s. sol. water.— CuA_2 : pale blue scales. S. -033 in the cold, -07 at 100° (Hoffmeister).— HgA_2 , aq: laminae. Mercuric nitrate gives a white flocculent pp. in a solution of leucine (R. Hoffmann, *A.* 87, 183).— PbA_2 , aq: ppd. by adding NH_4Aq to an aqueous solution of leucine and lead acetate (Strecker, *A.* 72, 89).

Benzoyl derivative $C_6H_5C(O)C_6H_{11}BzNO_2$, i.e., $C_6H_5(NHBz)CO_2H$. From leucine and $BzCl$ at 100° (Destrem, *Bil.* [2] 30, 481). Granules, sol. alcohol and ether. In the preparation of leucine anhydride there is also formed the anhydride $(C_6H_5(NHBz)CO)_2O$, which is an amorphous body [85°] insol. water and ether, v. s. sol. alcohol. Decomposed by boiling water into benzoic acid and the anhydride of leucine.

Phthalozyl derivative $C_6H_5(CO_2H)NH.CO.C_6H_4.CO_2H$ [132°]. From leucine, alcoholic KOH , and phthalyl chloride (Reese, *B.* 21, 277).— KA' : concentric groups of small slender needles.

Anhydride $(C_6H_5NO)_2O$. When the product of the action of $BzCl$ on leucine at 100° is treated with alcohol leucine anhydride remains undissolved, while its di-benzoyl derivative (v. supra) passes into solution (Destrem, *C. R.* 86, 484). Leucine anhydride is a white amorphous body, insol. alcohol, but becoming gelatinous when boiled therewith. It is not easily converted into leucine by boiling water.

• **LEUCINDIN SULPHONIC ACID v. INDIN.**

LEUCINIMIDE $C_6H_{11}NO$. Obtained in small quantity, together with leucine and tyrosine, by boiling proteids with dilute H_2SO_4 (Limpricht & Hesse, *A.* 118, 201; Erlenmeyer, *A.* 119, 17; Thudichum, *C. J.* 23, 409). Formed also when proteids are treated with bromine-water (Hlasiwetz & Hebermann, *A.* 159, 328), and, together with benzoyl-leucine, by heating leucine with $HOBz$ at 200° (Destrem, *Bil.* [2] 30, 481). Mi-

nute white trimetric needles; insol. cold, al. sol. boiling water, sol. alcohol, m. sol. ether. May be sublimed. Not affected by boiling aqueous acids or alkalis.

Iso-leucinimide $C_6H_{11}NO$. Formed by heating α -amido-isohexoic acid in a current of HCl at 225° (Köhler, A. 134, 869). Minute white needles (from alcohol), may be sublimed. Insol. water, sol. alcohol. Not affected by boiling KOH aq or by acids.

LEUCO-BROMO-QUINONE PHENOLIMIDE
v. BROMO-DI-OXY-DI-PHENYL-AMINE.

LEUCOGALLOL $C_{12}H_8Cl_2O_2$ 2aq. [104°]. Formed by passing chlorine into a cold mixture of pyrogallol (10 g.) and glacial acetic acid (20 g.), then adding conc. HCl aq (5 c.c.), and continuing the passage of chlorine. The pp. is washed with benzene, dissolved in ether, and ppd. with benzene (Stenhouse & Groves, C. J. 28, 1, 704). Crystalline crusts composed of small needles. Gives off HCl and water on fusion, and forms tri-chloro-pyrogallol and a body resembling quinone (Webster, C. J. Proc. 3, 130). V. sol. water and alcohol, m. sol. ether, insol. CS, and ligroin, al. sol. boiling benzene. Leucogallol is converted by zinc-dust and dilute H_2SO_4 to tri-chloro-pyrogallol $C_6Cl_3(OH)_3$ (Hantzsch a. Schnitzer, B. 20, 2033). It reacts with hydroxylamine and with phenyl-hydrazine. Its constitution may possibly be:

LEUCOLINE C_9H_7N . This base, occurring in coal tar, has been shown by Hofmann (A. 47, 76; 53, 427), Hoogeweff a. van Dorp (R. T. C. 1, 1, 107), and others to be identical with quinoline.

LEUCOLINIC ACID $C_9H_7NO_3$. [162°]. Obtained from coal-tar quinoline (leucolino) (10 g.) by dissolving as neutral sulphate and treating with $KMnO_4$ (25 g.) in boiling water, adding the latter solution slowly. Cold solution of $KMnO_4$ (40 g.) gives only pyridine carboxylic acids (J. Dewar, Pr. 26, 65; 30, 168).

Properties.—Needles. Often syrupy. It then becomes crystalline by boiling with water for some days. Sl. sol. cold water, sol. alcohol. The lead salt is insoluble. The silver salt forms slender needles.

Reactions.—1. The crystalline acid forms with glycerine a substance resembling indole. 2. A solution of the potassium salt at 200° gives aniline. 3. Potash fusion gives salicylic acid, CO_2 , NH_3 , and hydrogen. 4. When heated with *soda-lime* to a low red heat it forms aniline, NH_3 , and a small quantity of methyl-pyridine.

LEUCOMAINES. Bases occurring in living animals (Gautier, Bl. [2] 48, 16; cf. J. Ph. [5] 13, 354, 401; Bl. [2] 48, 158). *Левкомин*—white of egg. Obtained by extracting fresh beef (30 kilos) with tepid water (60 kilos) to which 25 g. oxalic acid and f. c.c. oxygenated water is added per litre. At the end of 24 hours the whole is heated to boiling, filtered, and evaporated at 50° in *vacuo*. The residue is extracted with 99 p.c. alcohol, filtered, evaporated in *vacuo*, redissolved in alcohol, filtered, and the alcoholic solution ppd. with ether. The precipitate may be separated by a series of crystalli-

sations from ether, alcohol, and water, and by precipitation with $HgCl_2$ into the six following bases.

Xantho-creatinine $C_5H_7N_3O$. Small sulphur-yellow micaceous laminae with greasy surface. Slightly bitter in taste. Gives off an odour like acetamide when heated. Smells in the cold like a dissecting room. When strongly heated it gives off an odour of roast beef, and carbonises, with evolution of NH_3 and methylamine. Neutral to litmus. Its hydrochloride and platinichloride are crystallisable and soluble. Its solution like creatinine is ppd. by $ZnCl_2$; this pp. crystallises from hot water on cooling in groups of needles. $AgNO_3$ gives a flocculent pp. crystallising from hot water in needles. Mercuric chloride gives a yellowish-white pp., sol. alcohol. It is not ppd. by iodine in KIAq. Sodium phosphomolybdate gives a pp. after a time. Treatment with H_2O forms a substance melting at 174° .

Chruso-creatinine $C_5H_7N_3O$. Crystals (from water). Feebly alkaline. Its hydrochloride crystallises in needles, is soluble and not deliquescent. The aurichloride is slightly soluble and forms crystalline grains. The platinichloride is soluble. Chruso-creatinine gives no pp. with zinc acetate or mercuric nitrate, but it ppts. alumina from alum. $ZnCl_2$ gives a crystalline powder. $HgCl_2$ gives a pp. I in KIAq gives a pp. Sodium phosphomolybdate gives an abundant yellow pp.

Amphicreatine $C_5H_7N_3O$. Feeble base, forming bright-yellow crystals. Its hydrochloride is crystalline and non-deliquescent. Its platinichloride is soluble and forms lozenge-shaped tables. It ppts. sodium phosphomolybdate, but not $HgCl_2$.

Pseudocreatine $C_5H_7N_3O$. Flesh-coloured powder composed of minute crystalline grains. Forms a very soluble hydrochloride, resembling that of hypoxanthine, crystallising in whetstone-like shapes. Its aqueous solution is ppd. by $HgCl_2$. $AgNO_3$ gives a gelatinous pp. Ppd. by ammoniacal but not by neutral lead acetate. When evaporated with HNO_3 like xanthine it leaves a residue which is turned orange-red by potash.

A base $C_{11}H_{12}N_4O_2$ crystallising in colourless rectangular tables, with crystalline hydrochloride and platinichloride.

A base $C_{12}H_{14}N_4O_2$ resembling both the preceding and xanthocreatinine.

LEUCONIC ACID $C_6(OH)_{10}$ or C_6O_5 5aq i.e.

croconic acid. Deca-oxypentamethylene. Prepared by adding finely powdered pure croconic acid (1 pt.) to cooled HNO_3 of S.G. 1.36 (6-8 pts.); the mixture solidifies to a magma of colourless needles, which are washed with ether-alcohol and finally with ether (Nietzki a. Benkiser, B. 19, 301; cf. Will, A. 118, 117; Lerch, A. 124, 20). Gum-like mass. V. e. sol. water, al. sol. alcohol, insol. ether. Sweet taste. It is readily reduced to orconic acid. By dissolving in alkalis it is entirely altered. Treated with α -amido-benzene it forms a violet colouring matter, turned brown by alkalis (Witt, C. J. 49, 403).— $KC_6H_4O_5$:

amorphous, sl. sol. water.— $\text{Ba}_2(\text{C}_2\text{H}_3\text{O}_2)_2$: flocculent pp.— $\text{Pb}_2(\text{C}_2\text{H}_3\text{O}_2)_2$: pp.— $\text{Ag}_2\text{C}_2\text{H}_3\text{O}_2$ (W.).

Penta-oxim $\text{C}_5(\text{NOH})_5$. Yellow crystalline solid. Formed by the action of hydroxylamine upon croconic or leuconic acid. Decomposes suddenly at 172° .— $\text{C}_5\text{H}_3\text{N}_5\text{O}_5\text{K}_2$: very explosive. The penta-oxim may be reduced by

SnCl_2 to $\text{CH}(\text{NH}_2)\text{C}(\text{NH}_2):\text{C}(\text{NH}_2):\text{C}(\text{NH}_2):\text{C}(\text{NH}_2)$ which forms crystalline salts.

Tetra-acetyl derivative of the penta-oxim $\text{C}_5(\text{NOH})(\text{NOAc})_4$ (aq from benzene). From the penta-oxim and Ac_2O at 45° (Nietzki a. Rosemann, B. 22, 916). Plates (from Ac_2O) or needles containing chloroform (from chloroform): Sl. sol. hot benzene. Decomposed at 100° .

Tetra-oxim $\text{C}_4\text{H}_4\text{N}_4\text{O}_4$ i. e. $\text{C}(\text{NOH})_4$. When potassium croconate (30 g.) is gradually added to a cooled mixture of HNO_3 (45 g. of S.G. 1.39) and water (40 g.), and the product is diluted with water (500 c.c.) and heated with hydroxylamine hydrochloride (180 g.) for some hours at 45° and finally at 100° there is formed a pp. of mixed oxims. This is dissolved in aqueous Na_2CO_3 and CO_2 is passed in, whereupon the penta-oxim is ppd. while the tetra-oxim can be ppd. from the filtrate by HCl . Yellow pp. Explodes at 160° . Its sodium derivative is v. sol. water, but is ppd. on adding alcohol or NaCl , apparently in the form of $\text{Na}_2\text{C}_4\text{H}_4\text{N}_4\text{O}_4$.

Carbonyl-di-toluquinoxaline $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}$ i. e.

$\text{C}_6\text{H}_5\text{N}(\text{CO})\text{C}(\text{NOH})\text{C}(\text{NOH})\text{C}(\text{NOH})\text{C}(\text{NOH})\text{C}_6\text{H}_5$. **Leuconic-acid-di-tolylene-o-diamide**. [above 300°]. Formed by adding a salt of tolylene-o-diamine to a cold aqueous solution of leuconic acid. Golden-yellow needles. V. sol. warm chloroform, sl. sol. hot alcohol and acetic acid, insol. water. Weak base.

Phenyl hydrazide $(\text{C}_6\text{H}_5\text{N}_2)_2\text{O}:\text{C}:\text{N}:\text{HPh}$: Red needles (from acetic acid); v. sol. chloroform, sl. sol. alcohol. Weak base. The hydrochloride forms a dark-green pp. (Nietzki a. Benkiser, B. 19, 776).

LEUCOTIN v. COTO BARK.

LEUCOTURIC ACID $\text{C}_8\text{H}_8\text{N}_4\text{O}_6$. **Oxalanthm.** Formed when a solution of alloxanic acid is rapidly boiled down to a syrup; cold water is then added which leaves the leucoturic acid undissolved (Schlieper, A. 56, 1). Formed also by reducing parabanic acid with zinc and HCl aq in the cold (Limpricht, A. 111, 134). White crystalline powder, insol. cold, m. sol. hot, water. Decomposes alkaline carbonates on boiling. Decomposed by heating with KOH , giving off NH_3 , and forming oxaluric acid. Its ammoniacal solution is ppd. by AgNO_3 , and on boiling reduction takes place. Boiling conc. HNO_3 does not attack it.

LEVONIC ACID $\text{C}_6\text{H}_6\text{O}_8$ 3aq. An acid said by Wiederhold (C. C. 1884, 974) to be obtained by boiling levulose with baryta-water. Yellowish-brown powder, v. sol. alcohol and water. Decomposed by heat.

LICARENE $\text{C}_{10}\text{H}_{16}$ (168°–172°). S.G. 1.855. An inactive terpene obtained by the action of ZnCl_2 or P_2O_5 on the essential oil of *Licari Kanali* (Morin, A. Ch. [5] 25, 427). Conc. HCl aq forms $\text{C}_{10}\text{H}_{16}\cdot 2\text{HCl}$, a colourless liquid, S.G. 1.1069, inactive to light, and decomposed on distillation into licarene and hydrochloric acid. The essential oil $\text{C}_{10}\text{H}_{16}\text{O}$ might be looked upon as licarene hydrate and exhibits the following properties:—(198°) at 755 mm. S.G. 1.8668. $[\alpha]_D^{20} = -19$ at 15° . It is sol. alcohol, ether, and glycerin.

LICHENINE $\text{C}_8\text{H}_{10}\text{O}_8$. Occurs in Iceland moss.

Preparation.—*Cetraria islandica* or other similar lichen is heated for several hours with a 2 p.c. solution of K_2CO_3 . The aqueous solution is ppd. by alcohol (Honig a. Schubert, M. 8, 460; cf. Knop a. Schnedermann, A. 55, 164; Maschke, J. pr. 61, 7; Davidson, N. Ed. P. J. 28, 260; Errera, Bn. 1, 882; Bauer, J. pr. [2] 34, 49; Klason, B. 19, 2541).

Properties.—Gelatinous pp., v. sl. sol. cold water. Boiling water forms an opalescent solution; reppd. on cooling or on adding alcohol. Gives no blue colour with I and H_2SO_4 . Dissolves in HCl , from which solution it is ppd. in snow-white flocks by alcohol. Weak hot acids convert it after some time into a dextro-rotatory sugar. $[\alpha]_D^{20} = +55^\circ$. Glucose is also formed. Two carbohydrates, resembling soluble starch in their properties, are present in the aqueous solution.

LICHENIC ACID $\text{C}_{10}\text{H}_{12}\text{O}_8$ (120°). Occurs in Iceland moss (Schnedermann a. Knop, A. 55, 149), and probably also in the fly-agaric or toadstool (Boley, A. 86, 50). Obtained by boiling Iceland moss for 15 minutes with dilute alcohol and some K_2CO_3 , filtering, adding HCl aq and 4 volumes of water. The pp. is boiled with alcohol of 45 p.c., whence a mixture of lichenic-stearic and cetraric acids separates on cooling. The lichenic-stearic acid is extracted from the mass by petroleum, and recrystallised from alcohol. Mass of radiating needles which soon change to delicate pearly laminae. Has a rancid taste. Insol. water, v. sol. alcohol, ether, and oils. Is not attacked by AcCl . On oxidation it yields CO_2 and decoic acid (Hilger a. Buchner, B. 23, 461). The ammonium salt forms a jelly containing extremely slender needles.— BaA'_2 : greyish-white pp. which cakes together in boiling water.— PbA'_2 : flocculent pp. fusing under water.— AgA' .

LIEBERMANN'S REACTION. A blue or green colour obtained by warming phenol with H_2SO_4 containing nitrous acid. It may be used as a test for phenol or for nitrous acid. Various derivatives of phenol may be used instead of phenol, while nitroso- and oximido-compounds usually react like nitrous acid.

LIGHT. For an account of the applications of optical methods of inquiry to chemical problems, v. PHYSICAL METHODS, section OPTICAL.

LIGNIFICATION v. LIGNONE.

LIGNO-CERIC ACID $\text{C}_{10}\text{H}_8\text{O}_8$ or $\text{C}_{10}\text{H}_{10}\text{CO}_2\text{H}$ [81°]. Occurs in the paraffin obtained from beech-wood tar (Hell, B. 13, 1709). Occurs also in the product of the saponification of earth-nut oil (Kreiling, B. 21, 880). Colourless felted needles or plates (from alcohol).

Salts.— $\text{A}'\text{Na}$: white powder.— $\text{A}'\text{K}$: white

powder, sol. alcohol.—A'Ag: white pp. [c. 155°].
—A'Cu: green powder, sol. hot benzene.—
A'Pb: white powder, [117°] v. sol. hot benzene.

Methyl ether A'Me. [58°]. White glistening plates. Sol. CS₂, CHCl₃, C₂H₅, ether, and ligroin; sl. sol. alcohol. Distills undecomposed at a high temperature.

Ethyl ether A'Et. [55°]; [310° at 20 mm.; 860° at 760 mm.]. Glistening plates.

Chloride C₂₂H₁₄COCl. [48°–60°]. Plates. Sol. ether.

LIGNONE (*Lignin, Lignose: Lignification*). Lignification, or the process of wood formation, is one of the principal of the modifications of the cell-wall, by which it and the tissues containing it are differentiated for fulfilling their several functions. The history of a lignified cell, or rather of the substance of the cell-wall, is usually stated to consist of (1) the elaboration of the primary cell-wall from materials in protoplasm, and formed at its limiting film as an envelope of pure cellulose; (2) the induration of this cell-wall, *i.e.* lignification, by the infiltration of substances, which when deposited are known as 'lignin,' or more vaguely as 'incrustative' substance. Lignification is recognised by the morphological changes with which it is associated, as well as by the very characteristic reactions of the product (Goodale, *Phys. Botany*, 1885). These products, although presenting a wide range of differences, corresponding with variations in structural and other characteristics of the tissue in which they occur, all naturally, and as regards their chief constituent, into a homogeneous chemical group, designated by the term lignocellulose, of which the typical features are represented in the substance of the jute fibre (vol. i. p. 719).

It is the purpose of this article to give a brief account of more recent researches into the constitution of this typical lignocellulose, and to show the bearings of the results arrived at upon the chemistry of the woods, the most numerous and important section of the group. The advantages of the jute fibre over the latter as a subject of study are that it is a simple tissue, whereas the woods are complex aggregates, that as an isolated fibred it is much more easy of penetration by reagents, and that as a product of only a few months' growth it has not undergone such secondary changes in composition as necessarily take place in the substance of a perennial stem or true wood. Such characteristics mark out the jute fibre substance as a natural basis for the general solution of the chemical problem of lignification.

Evidence has already been given (vol. i. loc. cit.) for regarding this product as chemically homogeneous, which view is further developed in the investigations referred to (C. J. 1889, 199). In all reactions in which hydroxyl groups only are brought into play—hydrolysis and etherification—it behaves as an integral compound (lignocellulose), of which the formula C₁₂H₁₀O₅ is an approximate empirical expression. The limit of 'nitration' is the tetrani- trate, indicating a number of OH groups in the original less by two than in the molecule of cellulose, similarly represented, *i.e.* as C₁₂H₂₀O₁₀. The product is of a bright gold colour, with a silky lustre. In further contradistinction to

cellulose, the OH groups of the lignocellulose react with acetic anhydride at its boiling-point. Its reaction with chlorine has been studied quantitatively; 1 grm. of the purified fibre-substance takes up 54–55 c.c. Cl (calc. at 0° and 760 mm.), or approximately 16 p.c. by weight, the quantity of Cl as HCl formed being equal to that entering the molecule. The chlorinated product n(C₁₂H₁₀Cl₂O₅)¹, a simple substitution-derivative of the non-cellulose constituent (which we may regard as n(C₁₂H₁₀Cl₂O₅)), contains mairgallol in combination with a body not yet completely studied, but yielding furalur on hydrolysis. In addition to the molecular groupings thus indicated, the presence of methyl groups is proved by the formation of methyl chloride on heating this compound, and of acetic acid on destructive distillation of the fibre substance, as also by dissolving it in sulphuric acid, diluting and distilling. These results afford a general view of the constitution of the 'lignin' substance, as it has been termed hitherto. We may regard it as containing closed C₆ chains, further characterised by the presence of ketone- or quinone-oxygen, and united to the furalur-yielding body, which is probably related to 'wood-gum' ('Holzgummi'). Tollens has, in fact, isolated xylose from the jute-fibre (B. 22, 1046), though in very small quantity, and we would note here the increase in the proportion of the parent substance, wood-gum, with the more advanced lignification of perennial stems, as additional evidence for this view. It is difficult to localise the methyl groups; but they would appear to be independent of the above, and may be regarded as existing in an acetic residue in combination. For a substance of marked ketonic and aldehydic characteristics, the terms *lignin* and *lignose* are obviously unsuited, and should give place, according to present views, to *lignone*, by which, therefore, we shall designate the non-cellulose component of the lignocelluloses generally.

The lignone of plant cells generally in the earlier stage of growth, *i.e.* lignification, appears to be not merely similar to but identical with that of jute. Proof of this has been afforded by the particular investigation of such widely differing structures as the stony concretions of pears—Erdmann's glycodrupose—the fibrovascular bundles of *Musa Paradisiaca* (Monocot.), and the bast fibres of the *Sida* species (C. J. 1882, 108; 1883, 10; 1889, 212).

But very few of the woods have been particularly investigated in regard to the constitution of the wood substance, and for the most part only in regard to the products of hydrolysis (v. vol. i. p. 719). Thus Erdmann concluded from his study of coniferous wood that its chief constituent—'glycolignose'—is a chemical individual C₁₂H₁₀O₅, a species of glucoside resolved by treatment with boiling acids into 'lignose' C₆H₁₀O₅ and a fermentable sugar (glucose). The presence of closed C₆ chains in the 'lignone' molecule was evidenced by its yielding protocatechuic acid on fusion with alkaline hy-

¹ A more direct conversion of the lignone into definitely aromatic products is that which takes place spontaneously when masses of jute are exposed to moisture and heat. From specimens of fibre 'rotted' under such conditions Cross and Bevan obtained an astringent substance C₁₂H₁₀O₅, which yielded phloroglucinol and protocatechuic acid on fusion with potash (C. & J. 1882, 53).

LIGNONE.

It was also concluded that the wood of the widely different poplar species was similar (not identical in composition (*A. Suppl.* 5, 28).

The later researches of F. Bente (*D. P. J.* 17, 235), although modifying these views, chiefly in the variation in the results of hydrolysis, nevertheless in the main confirm them. The general conformity of the woods to the types above described as representative is shown:

(1) In the close similarity of their characteristic reactions. Of these we may mention (a) the colouration produced with solutions of the aromatic amines (golden-yellow), and of solutions of the phenols in hydrochloric acid, most characteristic of which is the reaction with phloroglucinol (crimson); (b) the powerfully reducing action of the wood substance upon the oxides of copper, silver, gold, and mercury—showing the presence of aldehydic groups; (c) the reactions with the halogens yielding, in the case of chlorine, substitution products of definite quinone-chloride characteristics, attended by complete resolution into lignone (chloride) and cellulose: with bromine and iodine less definite compounds, but constant under constant conditions; (d) with nitric and sulphuric acids yellow-coloured explosive nitrates; (e) with acetic anhydride at its boiling-point and with benzoyl chloride in presence of alkalis, the corresponding ethereal derivatives; (f) with solutions of the caustic alkalis at 160°–190° with bisulphites (of the alkaline earths) at 150°–170° and with sulphurous acid (7 p.c. solution) at 90°–105°, attended by complete resolution into lignone (soluble derivatives) and celliclose (insoluble).

(2) In their empirical composition, which shows a remarkable uniformity throughout the group. This is illustrated in the appended table of results of analyses and determinations of calorific equivalents (Gottlieb, *J. pr.* [2] 28, 385):—

Wood	Ash	Nitrogen	Carbon	Hydrogen	Calorific equivalents per 1 gram
Oak . . .	0.37	—	50.16	6.03	4620
Ash . . .	0.57	—	49.18	6.17	4711
Hornbeam .	0.50	—	48.99	6.20	4728
Beech . . .	0.57	0.09	49.06	6.11	4777
Birch . . .	0.29	0.10	48.88	6.06	4771
Fir . . .	0.28	0.05	50.36	5.92	5035
Pine . . .	0.37	0.04	50.31	6.20	5085

An investigation by N. Schuppe of the chemical composition of a number of wood tissues (*Pharm. J.* [8] 14, 52) led to the following conclusions: (a) that the woods are uniform in their characteristics, being composed of cellulose and 'lignin' in somewhat variable proportions; (b) the cellulose when isolated (Schulze's process) having the composition $C_6H_{10}O_5$; and (c) 'lignin,' being represented by the empirical formula $C_{12}H_{16}O_4$, which is closely similar to that obtained for the 'lignone' of jute. Further, G. W. Hawes has examined the woods of typical acrogens, e.g. lycopodium, equisetum, and aspidium, and finds that they do not differ essentially in composition from exogenous woods (*Am. S.* [8] 7, 588).

Vol. III.

(8) In the products of their destructive distillation, which, when carried out under conditions, gives results which are similar for the several woods.

A series of such distillations by M. Senff (*B. 18, 60*), the results of which are given in percentages of the wood, are: (1) distillate, (2) tar, (3) crude anhydrous acid (acetic), (4) char. The following numbers represent the percentages observed: (1) 3–8, (4) 2–6, (5) 20–30, (6) 17–35.

Of all the more important species, e.g. *Quercus*, *Populus*, *Betula*, *Fagus*, and *Pinus*, were included in the research, and shown by the results to resemble one another very closely in composition. The products may be more particularly classified as regards the light which they throw upon the molecular grouping of the parent substance into: (a) members of the fatty series: alcohols, ketones, aldehydes, and acids generally of low molecular weights; (b) furfural and its homologues; (c) a group of aromatic bodies, constituting 'creosote,' which may be described as a mixture of guaiacol and creosol, containing besides, methyl-creosol and the dimethyl ethers of pyrogallol and its homologues in varying proportions (Schorlemmer, 'History of Creosote,' *S. C. I.* 4, 152). These divisions, it will be noted, correspond with the ascertained grouping of the complicated lignone molecule (*supra*), of which they afford additional confirmation. It is obvious that the process of destructive distillation must be attended with complications arising from secondary reactions, but the temperatures in the case of wood are sufficiently low to reduce these to a minimum: thus the yields of furfural are at a maximum when the temperature does not exceed 200° (Hcill, *B.* 10, 936), and the acetic acid is increased considerably beyond the percentages given by Senff (*supra*), viz. from 2–6 to 5–10, by raising the temperature very gradually through 150°–300° (W. Rudnew, *D. P. J.* 264, 88 & 128), no doubt at the expense of the methylation of the aromatic derivatives. This subject, however, except in regard to the outlines which we have sketched, belongs rather to the general theory of destructive distillation.

The fundamental tissue of the woods we regard, therefore, in all cases as a lignocellulose, of which the lignone portion, while possessing the typical characteristics common to the group, is no doubt variously differentiated with the special characteristics of families, and indeed species and individuals.

In addition to the fundamental tissue the woods contain other constituents, which from their nature are seen to be more or less adventitious. They are, in fact, generally removable by the action of solvents (in the case of resins, gum-resins, balsams, &c.), or by simple hydrolysis. In this group we may mention such definitely aromatic derivatives as coniferin and vanillin (M. Singer, *M.* 3, 395), the tinctorial constituents of the dye woods; also the very characteristic and important constituent of most exogenous woods known as 'wood-gum' (*Holz-gummi*), first described by Thomsen (*J. pr.* [2] 19, 146), who found quantities varying from 8 p.c. to 20 p.c. of the woods examined. This body yields on hydrolysis the C_6 sugar, xylose (Tollens, *Unters. a. d. Agr. Chem. Lab. Göttingen An.*

valen, 254, 325), which by further resolution yields furfural. Whether the wood-gum is a product of resolution of the lignone molecule has not yet been disclosed, but it would appear to be probable. A similar remark applies to the aromatic derivatives above mentioned.

In conclusion we must briefly notice a recent contribution to the subject of the 'constitution of lignin' (Lange, *Ztschr. Physiol. Chem.* 14, 217). This consists in a study of the soluble products of resolution of certain woods—beech, oak, and fir—by heating with strong solutions of the alkaline hydrates at 185°. In addition to formic and acetic acids, traces of higher fatty acids, oxalic acid and small quantities of pyrocatechol and protocatechuic acids, there were obtained certain amorphous bodies of brown colour, which the author terms lignic acids. These were resolved by treatment with alcohol into (a) soluble, (b) insoluble in this menstruum. The empirical composition of these derivatives is subjoined:

	(a)			(b)		
Lignic acids from	Beech	C. 61.3	H. 5.4	Oak	C. 59.0	H. 5.4
	Oak	C. 60.9	H. 5.4			
	Fir	C. 61.5	H. 5.0		C. 60.4	H. 5.0

The yield of these bodies is from 12-15 p.c. of the weight of the wood. The insoluble residues from the original alkaline digestion are described as 'celluloses,' but the description is doubtful. These results have an empirical value, but throw little light on the constitution of the wood substance. They afford additional evidence, however, of the general similarity of woods of various origin.

Digested with alkalis at higher temperatures (200°-250°) than those employed in the researches detailed above, the lignocelluloses are resolved for the most part into oxalic and carbonic acids. With potassium hydrate—which appears to give the maximum yield—the following proportions of oxalic acid have been obtained, the yield being calculated on the dry woods: pine, 94.7 p.c.; poplar, 93.2 p.c.; oak, 83.4 p.c. (W. Thorn, *D. F. J.* 210, 24). It is evident that the oxalic acid is derived from both lignone and cellulose, which are therefore probably similarly constituted as regards the arrangement of the C. atoms.

The action of the alkalis, however, at the point at which they resolve the lignocellulose is too severe to afford any trustworthy evidence, from the study of the products, as to the constitution of the original substance. The problem can only be solved by first studying those reactions which yield definite substitution or etheral derivatives; these are chiefly chlorination, conversion into nitrates, acetates, and benzoates, and the reaction with bisulphites (solutions) at high temperatures.

In this article we do not attempt a special description of the woods or their constituents; our endeavour is rather to generalise what is known concerning the wood substance proper, that which resists mechanical solvents altogether, and hydrolytic agents up to a certain degree of intensity. C. F. C.

LIGROIN. The mixture of homologues of methane obtained by collecting the portion of petroleum that boils below 100°.

LIGULIN. A crimson colouring matter in ripe privet berries (Nickles, *J. Ph.* [3] 35, 328),

sol. water and alcohol, insol. ether. Does not contain nitrogen. Coloured green by alkalis.

LIGUSTRIN. A yellow hygroscopic bitter mass extracted from leaves of the privet (*Ligustrum vulgare*), insol. ether and alcohol, sol. water and dilute alcohol. Conc. H_2SO_4 gives an indigo-blue solution (Polex, *Ar. Ph.* [2] 17, 76).

LIGUSTRON. [c. 100°]. (260°-280°). Occurs in privet bark (Reinsch, *J.* 1847, 787). Needles; v. sol. water, alcohol, and ether. Tastes bitter. Reduces ammoniacal $AgNO_3$.

LIME. Oxide of calcium, CaO ; v. vol. i. p. 666.

LIME, CHLORIDE OF. A name sometimes given to bleaching powder; v. BLEACHING POWDER, vol. ii. p. 17.

LIME LEAF OIL. The fragrant oil obtained by distilling the leaves of *Citrus Limetta* with steam contains a citrene (c. 176°), inactive to light, and with refractive index for red rays 1.4611 at 30°, terpinol, methyl ethyl ketone, and a colophene (F. Watts, *C. J.* 49, 316).

LIMES, OTTO OF. Obtained by rasping and squeezing from the unripe peel of the fruit of *Citrus limetta*. Contains a terpene (176°) and a soft resin, not volatile at 250°. On standing the resin deposits $C_{22}H_{34}O_2$ [102°] (Wright a. Piesse, *C. J.* 32, 518).

LIMETTIC ACID $C_{11}H_{16}O_6$. Obtained by the action of H_2SO_4 and $K_2Cr_2O_7$ on the oil of lime (from *Citrus Limetta*) and on oil of rosemary (Vohl, *N. Ber. Arch.* 74, 16). White crystalline body; may be sublimed. Has no taste or smell. Sl. sol. water, v. sol. alcohol.— Ag_2A' : powder, sl. sol. water, blackening on exposure to light.

LIMETTIN $C_8H_{14}O_6$. [122°]. A neutral body occurring in oil of limes (Tilden, *C. J. Proc.* 6, 30). Tufts of pale-yellow needles (from alcohol). Not acted upon by $AcCl$ or by phenylhydrazine. Bromine forms colourless scales of $C_{10}H_{16}Br_2O_6$. Boiling conc. $NaOH$ forms $NaOAc$ and crystalline $C_8H_{11}(OH)O_4$.

LIMONENE. A terpene occurring in oil of lemon and in many other essential oils; v. TERPENES.

LIMONIN $C_{22}H_{34}O_2$. [275°]. (Paterno a. Ogliastro, *G.* 9, 64); [245°] (Hoffmann, *Ar. Ph.* [3] 14, 839). A bitter substance contained in the pips of oranges and lemons (Bernays, *Buchner's Rep.* [3] 21, 306; *A.* 40, 317; Schmidt, *A.* 51, 338). The pips are exhausted with boiling water, alcohol is added, and the mixture is boiled with inverted condenser. After filtering, and distilling off the alcohol, limonin is left, together with a fatty substance which may be removed by CS_2 . 1500 g. of pips yield 80 g. of limonin (P. a. G.). Lamine; sl. sol. water, ether, and NH_4Aq , v. sol. alcohol, $HOAc$, KOH , and baryta-water. The barium salt is not decomposed by CO_2 . Conc. H_2SO_4 forms a red liquid, from which the limonin is ppd. by water.

LINALOES OIL. The essence of linaloes, obtained from the wood of *Licari kanali*, the white cedar of Cayenne, is a slightly coloured liquid with an odour like rose and lemon. After distillation over $CaCl_2$ it consists of $C_{10}H_{18}O$ (198°) S.G. 12.868, $[n]_D = -19$ at 15°. It is sol. alcohol, ether, and glycerol. When distilled with $ZnCl_2$ it yields a terpene, v. LICALBEN. By prolonged treatment with saturated $HClAq$ and

posure to light it yields $C_{18}H_{34}BrO_2$, an optically inactive liquid with a camphor-like odor, and S.G. 1.060. When distilled with lime it yields linoleic acid, $C_{18}H_{32}O_2$ (c. 170°), S.G. 0.885 (Morin, C. R. 92, 998; 94, 738).

LININ. C. 62-9 p.c. H. 4-7 p.c. A crystallisable substance obtained by digesting *Linum catharticum* with milk of lime, filtering, ppg. with HCl, and extracting with ether (Pagenstecher, A. 40, 22; C. Schröder, N. Rep. Pharm. 10, 11). Silky crystals, v. sl. sol. water, v. e. sol. alcohol and ether, m. sol. chloroform and HOAc. The alcoholic solution is intensely bitter.

LINOLEIC ACID $C_{18}H_{32}O_2$. *Linolic acid.* G. 1.92. Occurs as glyceryl ether in linseed oil, hemp oil, poppy oil, olive oil, nut oil, cottonseed oil, earth-nut oil, almond oil, oil of sesame, alm. oil, cacao butter, and probably in most seed vegetable oils (Pelouze, A. Ch. [3] 59, 3; Laurent, A. Ch. [2] 65, 150, 298; Liebig, A. 3, 113; Sacc, A. 51, 214; Schüler, A. 101, 252; Oudemans, J. 1858, 304; Hazura a. Grüssner, M. 9, 944; 10, 242; Benedikt a. Hazura, M. 10, 353). It does not occur in animal oils, so that when the acids obtained by saponifying animal oils are oxidised by $KMnO_4$, no sativic acid will be formed, but di-oxy-stearic acid will be among the products, this being derived from oleic acid (B. a. H.).

Preparation.—Crude linseed oil or hemp oil is evaporated with aqueous NaOH, the sodium soap is decomposed by H_2SO_4 , and the crude acid dissolved in alcohol, neutralised with NH_3 , and ppd. by $BaCl_2$. The barium salt is dissolved in ether, HCl is added, the ether decanted from ppd. $BaCl_2$, evaporated, and the liberated acid dried *in vacuo* over H_2SO_4 (Schüler; Bauer a. Hazura, M. 7, 216). The acid so obtained is a mixture of oleic, linoleic, linolenic, and isolinolenic acid (Hazura). By treatment with bromine at 0° and reduction of the product $C_{18}H_{34}BrO_2$ with zinc and HCl pure linoleic acid is got.

Properties.—Faintly-yellow limpid oil. Does not solidify at -18° . Insol. water, v. sol. ether, m. sol. alcohol. When distilled under 90 mm. pressure one-third passes over at 290° , and the distillate contains sebatic acid $C_{16}H_{30}O_2$ [130°] and an oily mixture (Hazura a. Grüssner, M. 9, 206; cf. Norton a. Richardson, B. 20, 2735).

Reactions.—1. Potash-fusion gives myristic, acetic, and formic acids, with traces of azelaic acid.—2. $KMnO_4$, hydrogen peroxide, and MnO_2 with H_2SO_4 oxidise it to azelaic acid.—3. $KMnO_4$ in presence of KOH aq converts it into sativic acid, some azelaic acid also being formed. But alkaline $KMnO_4$ oxidises crude linoleic acid from linseed oil (100 g.) into sativic acid $C_{18}H_{30}(OH)_2O_2$ [173°] (6.5 g.), linusic acid $C_{18}H_{30}(OH)_2O_2$ [204°] (4.5 g.), isolinolenic acid [175°] (15.8 g.), and di-oxy-stearic acid $C_{18}H_{32}(OH)_2O_2$ [137°] (1.2 g.) (Hazura, M. 9, 180; cf. Dieff a. Reformatsky, B. 20, 1211). It appears therefore that crude linoleic acid consists of linoleic acid $C_{18}H_{32}O_2$ (which gives sativic acid on oxidation), linolenic acid $C_{18}H_{30}O_2$ (which gives linusic acid), isolinolenic acid (which gives isolinolenic), and oleic acid (which gives di-oxy-stearic acid). The formation of sativic acid in this manner may be made use of as a test for linoleic acid.—4. Bromine at ordinary temperatures forms with crude linoleic

acid solid $C_{18}H_{34}BrO_2$ [177°]. Bromine at 0° forms a tetrabromide $C_{18}H_{32}Br_4O_2$ [115°] (Hazura, M. 8, 147; Hazura a. Friedrich, M. 8, 155, 285). Of these two compounds the former is formed from linolenic, the latter from linoleic acid. Pure linoleic acid gives only $C_{18}H_{34}BrO_2$ [115°].—5. Fuming $HIAq$ and amorphous phosphorus converts it into stearic acid (Peters, M. 7, 552).

Salts.—The salts are not crystalline. With the exception of the salts of the alkalis they are insol. water. They are sol. ether. With the exception of the Pb, Mn, Na, and NH_4 salts they are insol. alcohol.— BaA' (Peters).

Linolenic acid $C_{18}H_{30}O_2$. Obtained by treating the compound $C_{18}H_{34}BrO_2$ [177°] (*v. supra*) dissolved in alcohol with zinc and HCl (Hazura, M. 8, 267). Yields on oxidation by alkaline $KMnO_4$ no solid acid except linusic (hexa-oxy-stearic) acid [201°]. Bromine forms only $C_{18}H_{34}BrO_2$ [177°]. Linolenic acid 'dries' rapidly when exposed to air, through oxidation. Its salts behave in like manner. The more glyceryl linolenate there is in an oil the more rapidly does it dry. Glyceryl linolenate and isolinolenate also possess drying properties, but glyceryl oleate does not. The product produced by exposing the acids to air is an anhydride, insol. ether, but furnishing soluble acids when heated with alkalis.

Isolinolenic acid $C_{18}H_{30}O_2$. An acid assumed to exist in crude linoleic acid on account of the formation of isolinolenic acid on its oxidation. When crude linoleic acid is oxidised by $KMnO_4$ in alkaline solution, and the product ppd. by H_2SO_4 , there is obtained a mixture of fatty acids whence cold ether extracts di-oxy-stearic acid, sativic acid remaining undissolved. The filtrate from the ppd. acids is neutralised with NaOH, evaporated, again ppd. with H_2SO_4 , the pp. extracted with ether, and the residue crystallised from alcohol and then from water, whereby it may be separated into linusic and isolinolenic acids.

LINSEED OIL. The oil expressed from the seeds of flax (*Linum usitatissimum*). Like other drying oils when exposed to the air it dries up to a transparent resinous mass. Linseed oil is composed of the glyceryl ethers of oleic, linoleic, linolenic, and isolinolenic acids. *v. LINOLEIC ACID.* Linseed oil dissolves some oxide of lead when heated therewith, being decolourised and rendered more easily drying (boiled 'oil').

LINUSIC ACID *v. HEXA-OXY-STEARIC ACID.*

Isolinusic acid *v. HEXA-OXY-STEARIC ACID.*

LIQUIDAMBAR. A balsam obtained from a large tree, *Liquidambar styracifolia*, growing in Florida and Mexico. It resembles balsam of Peru, containing cinnamyl cinnamate, styrene, and cinnamic acid (Harrison, Ar. Ph. [3] 6, 541; Maisch, Ar. Ph. [3] 6, 545).

LIQUIDS. diffusion, dispersion, osmose, refraction, transpiration, of; *v. PHYSICAL METHODS.*

LITHIUM. Li. At. w. 7.01. Mol. w. probably 7.01 (*v. p.* 149). [180°] (Bunsen, J. 8, 524). S.G. .578 to .589 (Bunsen, *l.c.*). S.H. 27° to 100° = .9408 (Regnault, A. Ch. [8] 63, 11). E.C. at 20° (Hg at 0° = 1) 10.69 (Matthiessen, P. M. [4] 12, 199; 18, 81). Characteristic lines in emission spectrum are λ in the red 6705.2, and a

weaker line in the orange 6102, and a weak line in the blue 4602·7 (Thalén, 1868; v. also L. de Boissandran, *Spectres Lumineux*, p. 55; Schön, W. 10, 148; Liveing & a. Dewar, T. 1883. 187). S.V.S. 11·9.

• *Occurrence.*—Salts of Li are very widely distributed, but occur only in small quantities. Several phosphates of Fe and Al contain Li phosphate, especially *triphyline*, which contains c. 7 p.c. Li₂O; many silicates of Al and Fe contain small quantities of Li silicate, especially *lepidolite*, which sometimes contains from 3 to 5 p.c. Li₂O. Tourmalines, borates, &c., often contain traces of lithia. Very many mineral springs contain lithia; according to Kirchhoff & Bunsen lithia is present in almost all mineral waters (P. 113, 357). Truchot found lithia in the soil of Limargue in the Auvergne; nearly all the plants growing on this soil take up lithia (C. R. 78, 1022). Dieulaufait has found traces of Li in sea-water from all parts of the globe, in the water of marshes, in mineral springs, in primary rocks, in gypsum of different formations (A. Ch. [5] 17, 377). Lithia is found in many plants, and in all sorts of tobacco; but not in raw sugar, cocoa, coffee, or tea (Focke, *Der Naturforscher*, 1872. 407; Grandeau, A. Ch. [3] 67, 216). Lithia has also been found in the milk and blood of cows (Bunsen & Kirchhoff), in different parts of the human organism (Bence Jones, P. M. [4] 29, 391), and in normal urine (Schiaparelli & Peroni, G. 10, 390).

While investigating various silicates in 1817, Arfvedson (S. 22, 93; 34, 214) found a new alkaline base with a molecular weight smaller than that of soda or potash. Berzelius gave the name *lithia* to the new base (*λίθιος*) supposing that, unlike soda and potash, it was to be found only in minerals. The new alkali was decomposed by electrolysis in 1818 by Davy, also in 1820 by Brandes (S. 8, 120); but the metal was first prepared approximately pure and in considerable quantity by Bunsen and Matthiessen in 1855 by electrolyzing fused LiCl (A. 94, 107).

Preparation.—The metal is obtained by electrolyzing molten LiCl. Bunsen & Matthiessen (A. 94, 107) passed the current from 4–6 Bunsen-cells through LiCl kept molten in a thick-walled porcelain crucible, using a cylindrical rod of retort graphite as positive electrode, and an iron wire the thickness of an ordinary knitting needle as negative electrode. The metal separated on the iron wire in small pellets, which were quickly removed by an iron spoon and placed under petroleum. Some of the metal was always oxidised, occasionally with ignition. To obviate this, Hiller (*Neues Handwörterbuch der Chemie*, 3, 534) passed the negative electrode (iron wire) through the stem of a tobacco-pipe, which he connected with an apparatus supplying pure dry H₂; he allowed H to pass through the pipe until air was completely expelled, then plunged the bowl open end downwards, with the end of the wire inside, into the molten LiCl; stopped the H, and sent the current through the LiCl; when sufficient Li had collected inside the bowl, the pipe was broken and the metal collected under petroleum. To prevent any action between the Li and the silica in the pipe, the inside of the bowl is covered with a thin layer of graphite; this is done by mixing powdered graphite with

dilute LiClAq so as to form a thick paste, spreading this inside the bowl, and drying first in air and then at a moderate red heat. It is advantageous to mix the LiCl before fusion with some NH₄Cl.

There are many methods for preparing LiCl from Li-containing minerals; the methods vary according to the composition of the mineral dealt with, all seek to prepare a solution containing only the alkalis, from which Li may be separated by taking advantage of the comparatively small solubility in water of Li₂CO₃. LiCl is obtained by dissolving Li₂CO₃ in HClAq, evaporating, and drying the crystals which separate. Lepidolite is the usual starting-point; different specimens contain from less than 2 to c. 5 p.c. Li₂O. The mineral is very finely powdered and triturated with water; the finest powder is dried and heated to redness with twice its weight of lime; the cold mass, in which the SiO₂ is combined with lime, is treated with HClAq; CaO is pptd. from the solution by H₂SO₄Aq and evaporation; the filtrate is evaporated to dryness, and the solid is heated until H₂SO₄ is all removed; the residue is dissolved in water, the solution is digested with CaCO₃ to remove Al₂O₃, and Ca is removed by pptn. with (NH₄)₂C₂O₄; the filtrate is evaporated to dryness, and the residue is strongly heated; the Li₂SO₄ thus obtained is dissolved in water, and the liquid is pptd. by Ba acetate; after filtration the Li acetate is strongly heated and so transformed into Li₂CO₃ (Arfvedson, S. 22, 93; 34, 214).

The method recommended by v. Haur (J. pr. 68, 310) consists in strongly heating for 2 hours a mixture of equal parts of very finely powdered lepidolite and gypsum, lixiviating the mass with water, filtering, evaporating until CaSO₄ and K₂SO₄ crystallise out, adding to the mother-liquor a mixture of NH₄Aq, NH₄HSAq, and (NH₄)₂C₂O₄Aq, whereby all bases are pptd. except the alkalis; after filtering, Li₂CO₃ is pptd. from the warm solution by (NH₄)₂CO₃.

The process adopted in Schering's manufactory at Berlin is described by Filsinger (D. P. J. 219, 183; 222, 321, 385). Finely ground and sifted lepidolite is mixed with conc. H₂SO₄ in a warm brick trough to the consistence of a thin paste, which is heated with slight stirring till it forms into lumps; the lumps are calcined in a reverberatory furnace, and, while warm, are lixiviated with water; the liquid is mixed with enough K₂SO₄ to convert all Al₂O₃ into alum, which separates on boiling, the residual Al₂O₃ being removed by milk of lime; the salts in the filtrate are converted into chlorides by pptn. with BaCl₂Aq, and the liquid is evaporated to dryness; digestion with absolute alcohol dissolves the chlorides of Li and Ca; after distilling off alcohol, Ca is pptd. by (NH₄)₂C₂O₄Aq, the liquid is filtered, and a little NH₄HSAq is added to ppt. any Fe, &c., still present; the filtrate is boiled to remove NH₄H₂ and evaporated to dryness in a silver dish; pure LiCl is thus obtained. The LiCl may be converted into Li₂CO₃ by dissolving in water, adding NH₄Aq and (NH₄)₂CO₃, and washing the pp. with alcohol of 60 p.c.

Schrötter's method is said to be one of the best (J. pr. 93, 275). Lepidolite is melted, at full red heat, with frequent stirring; the molten mass is ladled out by an iron spoon into water;

when cold the solid is powdered and triturated with water; HClAq S.G. 1.2 is added little by little to the pasty mass; care must be taken that sufficient water is present to prevent the whole mass from solidifying; after standing for 24 hours, with frequent stirring, the semi-liquid substance is heated nearly to boiling, and a little more HClAq S.G. 1.2 is added; the total quantity of HCl used should be c. 2 parts to 1 part lepidolite; after a few hours most of the SiO_2 has separated; a little of the filtered liquid should be so acid that no permanent pp. is formed on addition of a few drops of Na_2CO_3 Aq; a little HNO_3 Aq is now added to completely oxidise FeCl_2 to FeCl_3 ; the liquid is filtered from ppd. SiO_2 (which separates as a powder), and Fe_2O_3 , Al_2O_3 , CaO , MgO , &c., are ppd. by careful addition of Na_2CO_3 Aq to the boiling liquid. The alkaline filtrate is nearly free from all salts except chlorides of the alkalis; it is evaporated until the small quantities of MgCO_3 , MnCO_3 , &c., still present separate out, and Li_2CO_3 is ppd. from the filtrate by addition of Na_2CO_3 and evaporation.

Commercial Li_2CO_3 generally contains small quantities of salts of Mg, Ca, K, Na, &c.; it may be purified by one of the foregoing methods. For the other methods of preparing Li_2CO_3 from lepidolite, &c., v. Hugg, Müller, *J. pr.* 58, 148; Fuchs, *J. pr.* 5, 319; Troost, *A. Ch.* [3] 51, 103; Mallet, A. 101, 389; Lunglmayr, *D. P. J.* 171, 293; Allen, *J. pr.* 87, 480; Reichardt, *D. P. J.* 172, 447; L. Smith, A. 159, 82; Stolba, *D. P. J.* 198, 225; L. de Boisbaudran, *B.* [2] 17, 551. A detailed criticism of various methods will be found in *D. P. J.* 219, 183; 222, 271, 385.

Properties.—A silver-white metal; very soft, but harder than K or Na; when freshly cut, the surface appears yellowish; when melted and at once pressed between glass plates, it forms a silver-like mirror. Li makes a grey streak on paper. It may be drawn into wire, but shows very little tenacity. Li is the lightest known solid; S.G. c. .59; it swims on rock oil. Melts at 186° . Is not acted on by dry O at its M.P.; heated in air to c. 200° it burns with a very brilliant white flame. May be vapourised in Hat full red heat. Li decomposes cold water without itself melting; it combines rapidly with Cl, Br, I, S, O; it burns when heated in dry CO_2 . Li reacts with most acids to form salts; conc. HNO_3 Aq oxidises it with great rapidity, the metal usually melts, and is sometimes ignited. Li dissolves in liquid NH_3 , and on evaporation of the NH_3 it is left unchanged (Seeley, *C. N.* 23, 169).

The atomic weight of Li has been determined: (1) By converting LiCl into AgCl (Arfvedson, S. 22, 93; Mallet, *Am. S.* [2] 22, 349; Troost, *A. Ch.* [3] 51, 108; Stas, *Nouv. R.* 268); (2) by determining O in Li_2O (Berzelius, P. 17, 379); (3) by ppg. Li_2SO_4 by BaCl₂ (Berzelius, P. 17, 379; Hermann, P. 15, 482; Hagen, P. 48, 361; Diehl, A. 121, 97); (4) by determining CO_2 in Li_2CO_3 (Hermann, P. 15, 480; Troost, *A. Ch.* [3] 51, 108; Diehl, A. 121, 93); (5) by converting Li_2CO_3 into Li_2SO_4 (Troost, *A. Ch.* [3] 51, 108); (6) by converting LiCl into LiNO_3 (Stas, *Nouv. R.* 274); (7) by determining S.H. of Li (Regnault, *A. Ch.* [3] 68, 11).

Ramsay (*C. J.* 55, 521) has endeavoured to

determine the mol. w. of Li by measuring the lowering of vapour-pressure of Hg produced by dissolving Li in Hg; the results make it probable that the mol. w. of Li is the same as the at. w. This result is based on the assumption that Van't Hoff's law holds good, viz., that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances; it also presupposes that the molecular weight of liquid Hg is the same as the atomic weight.

As the V.D. of no Li compound has yet been determined, the valency of the atom Li in gaseous molecules is not certainly known, but from the close analogy between Li and the other alkali metals there can be little doubt that the atom of Li is monovalent in gaseous molecules.

Li is a strongly positive metal; it belongs to the group of alkali metals, none of which shows any tendency to enter into the negative radicle of salts. Li shows closer resemblances to the alkaline earths than are exhibited by any other metal of the alkalis; LiOH , Li_2CO_3 , and Li_3PO_4 are much less soluble in water than the corresponding compounds of Na, K, Rb, and Cs; Li does not form an alum. The position and analogies of Li are discussed in the article ALKALIS, METALS OF THE, vol. i. p. 114.

Reactions and Combinations.—1. Li decomposes cold water rapidly without itself melting. Thomsen (*Th.* 3, 227) gives the thermal data [Li , H^+O Aq] = 48,970 (to form LiOH Aq + H).—2. Very rapidly oxidised by conc. nitric acid.—3. Slowly acted on by conc. sulphuric acid; rapidly dissolved by dilute H_2SO_4 Aq, also by dilute hydrochloric acid (Matthiessen, A. 94, 10). 4. Burns when heated in dry carbon dioxide or sulphuretted hydrogen.—5. At temperatures lower than its melting-point Li acts on silica, alkaline silicates, iron, gold, silver, and platinum.—6. Combines readily with sulphur, phosphorus, and the halogens.

Detection.—Li compounds give a red colour to a non-luminous flame. Examination by the spectroscope will detect .000009 mgrms. Li present as LiCl (Bunsen). To detect Li in silicates, the powdered mineral is treated with HFAq , the liquid is poured off, and the residue is evaporated with addition of a little H_2SO_4 ; the residue is extracted with absolute alcohol, and the liquid is evaporated to dryness; the residue is again treated with absolute alcohol, and this solution is again evaporated, and the residue (.10 mgm. is sufficient) is examined in the spectroscope; if the mineral is non-siliceous, the treatment with HFAq may be omitted. Li is estimated in the form of Li_2SO_4 .

Lithium, antimonate of. LiSbO_3 . By adding LiCl to KSbO_3 Aq (cf. ANTIMONATES, vol. i. p. 285).

Lithium, borate of. $\text{Li}_2\text{B}_2\text{O}_7$, and hydrates with $5\text{H}_2\text{O}$, $6\text{H}_2\text{O}$, and $10\text{H}_2\text{O}$; by adding Li_2CO_3 to boric acid solution (Arfvedson, *A. Ch.* [2] 10, 82; Filsinger, *Ar. Ph.* [3] 8, 198; cf. BORATES, vol. i. p. 529).

Lithium, borofluoride of. By double decomposition between $\text{Ba(BF}_4)_2$ Aq and Li_2SO_4 Aq and evaporation at 40° , large deliquescent prisms are obtained, sl. sol. water; these crystals are probably LiBF_4 , but they have not been accurately examined (Berzelius).

Lithium, bromide of. LiBr . H.F. $[\text{Li}, \text{Br}, \text{Aq}] = 91,810$ (*Th.* 3, 227); $[\text{LiBr}, \text{Aq}] = 11,350$ (Bodisko, *J. R.* 1889, [1] 7). S.G. 3.102 at 17° (Clarke, *Am. S.* [3] 13, 293). A white crystalline, very deliquescent, mass. Obtained by dissolving Li_2CO_3 in HBrAq and evaporating (Froost, *A. Ch.* [3] 51, 103); or by ppg. excess of CaBr_2 by K_2CO_3 , after 24 hours adding enough Li_2CO_3 to ppt. all the Ca , filtering, and evaporating (Klein, *A.* 128, 239). S. 143 at 0°, 196 at 34°, 222 at 59°, 244 at 82°, 270 at 103° (Kremers, *P.* 103, 65).

Lithium, chloride of. LiCl . S.G. 2.074 at 8.9° (Schröder, *P.* 106, 226), 1.998 at 0°, 1.515 at M.P. (Quincke, *A.* 138, 141); S.G. fused 1.575 (Wernicke, *P.* 138, 141). H.F. $[\text{Li}, \text{Cl}] = 93,810$; $[\text{LiCl}, \text{Aq}] = 102,250$ (*Th.* 3, 227). S.H. .282 (Regnault).

Preparation.—1. By dissolving Li_2CO_3 in HClAq and evaporating.—2. By decomposing Li_2SO_4 by BaCl_2 Aq , filtering from BaSO_4 , and evaporating.

Properties.—Crystallises from aqueous solution in regular octahedra; very deliquescent, more so than CaCl_2 ; tastes like NaCl ; melts at dark-red heat to a clear liquid, which gives off some Cl and becomes alkaline when heated for a long time in the air; the same change occurs to a slight extent when LiClAq is evaporated. E. sol. alcohol, also in a mixture of ether and alcohol in which KCl and NaCl are nearly insoluble. Volatilised at white heat. S. 63.7 at 0°, 80.7 at 20°, 104.2 at 65°, 115 at 80°, 129 at 96°, 139 at 140°, 145 at 160°. Gerlach (*Fr.* 8, 279) gives the following:—

S.G. LiClAq	P.e. LiCl	S.G. LiClAq	P.e. LiCl
1.006	1	1.148	25
1.030	5	1.182	30
1.058	10	1.219	35
1.086	15	1.256	40
1.117	20		

B.P. of saturated $\text{LiClAq} = 171^\circ$ (Kremers, *P.* 103, 65).

Reactions.—1. Heated in air for some time is partially decomposed with evolution of Cl ; residue is alkaline (Schulze, *J. pr.* [2] 21, 407). Evaporation of LiClAq is accompanied by slight decomposition.—2. Completely decomposed by heating in steam, with evolution of HCl ; decomposition is rapid in presence of silica, but is prevented by admixture of NH_4Cl (Kunheim, *J.* 1861, 149).

Combinations.—1. With water to form two hydrates. (1) $\text{LiCl} \cdot 2\text{H}_2\text{O}$; obtained as quadratic crystals by evaporating LiClAq under 10°. Dried between paper, the crystals become opaque and powdery; when warmed, melts in water of crystallisation, then solidifies, and then the dry LiCl melts again at red heat; (2) by evaporating a solution of LiCl in aqueous alcohol, Rammelsberg obtained the monohydrate $\text{LiCl} \cdot \text{H}_2\text{O}$ (*P.* 66, 79).—2. With alcohol to form $\text{LiCl} \cdot 2\text{C}_2\text{H}_5\text{O}$, and with methyllic alcohol to form $2\text{LiCl} \cdot 3\text{CH}_3\text{O}$; obtained by evaporating solution of LiCl in the respective alcohols (Simon, *J. pr.* [2] 20, 371).—3. With platinum chloride, to form $\text{Li}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$; orange-red salt, sol. in water, alcohol, and ether-alcohol.

Lithium, chromate and dichromate of; v. vol. ii. pp. 155, 157.

Lithium, fluoride of. LiF . Small crystalline tablets; by dissolving excess of Li_2CO_3 in HFAq , filtering, and evaporating. Slightly sol. in water; melts at red heat (Berzelius, *A.* 1, 17). S.G. 2.295 at 21.5° (Clarke, *Am. S.* [3] 13, 292). By solution of LiF in HFAq and evaporation, crystals of $\text{LiF} \cdot \text{HF}$ are obtained; when heated LiF and HF are formed. Flückiger (*A.* 87, 261) describes the double salt $2\text{LiF} \cdot \text{SbF}_3$. LiF combines with SiF_4 to form the *silicofluoride* Li_2SiF_6 (v. LITHIUM, SILICOFLOURIDES or, p. 151).

Lithium, haloid compounds of. Lithium combines directly with the halogens; the haloid compounds, LiX , are generally prepared by dissolving Li_2CO_3 in the respective acids and evaporating. As the V.D. of none of the compounds has been determined, their molecular weights are not known with certainty; but from the close similarities between compounds of Li , K , Na , and Cs there can be little doubt that the formula LiX ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$) expresses the composition of the molecules of the haloid compounds of Li .

Lithium, hydrosulphide of. LiSH . Obtained by reducing Li_2SO_4 by C , and passing H_2S into a solution of the product. Only known in solution (Berzelius, *P.* 6, 439). Thomsen gives H.F. $[\text{Li}, \text{S}, \text{H}, \text{Aq}] = 66,120$ (*Th.* 3, 227).

Lithium, hydroxide of. LiOH . Obtained by boiling Li_2CO_3 with CaOAq in a silver dish (Pt cannot be used as it is acted on by LiOH), filtering, evaporating, and heating to 100°; better by ppg. Li_2SO_4 Aq by an equivalent quantity of BaOAq , filtering, evaporating, and heating to 100°. Also obtained by dissolving Li_2O (q. v.) in H_2O and evaporating. Thomsen (*Th.* 3, 227) gives H.F. $[\text{Li}, \text{O}, \text{H}, \text{Aq}] = 117,440$; and heats of neutralisation $[2\text{LiOHAq}, \text{H}^+\text{SO}_4\text{Aq}] = 31,290$; $[2\text{LiOHAq}, \text{H}^+\text{ClFAq}] = 27,700$. Beckett (*Bt.* 41, 312) gives $[\text{Li}^+\text{O}, \text{Aq}] = 13,000$ (to form LiOHAq).

A white crystalline mass which melts when heated, without decomposition; sol. in water, but less so than KOH or NaOH ; insol. in ether-alcohol. Gmelin obtained small crystals of LiOH by evaporating a solution *in vacuo*; according to Muretow (*B.* 5, 331) the crystals are a *hydrate of lithium hydroxide*, $\text{LiOH} \cdot \text{H}_2\text{O}$ (cf. Dittmar, *S. O. I.* 7, 730).

Lithium, iodide of. LiI . Obtained by saturating HIAq , containing a little H_3PO_4 , with Li_2CO_3 , warming the ppd. Li_3PO_4 with BaI_2 , and a trace of H_2SO_4 , filtering, adding enough Li_2CO_3 to decompose excess of BaI_2 , present, filtering again, evaporating, crystallising, and drying by pressure between filter paper (Liebig, *A.* 121, 222). Liebig (l.c.) also recommends to neutralise half of an HI solution containing a little H_3PO_4 by BaO or CaO , to add the other half of the acid, neutralise by Li_2CO_3 , filter from Ba or Ca phosphate and evaporate. The crystals are generally yellowish from a little separated I ; this is removed by quickly pressing between filter paper. LiI forms small, colourless, deliquescent crystals. S.G. 3.485 at 28° (Clarke, *Am. S.* [3] 13, 293). H.F. $[\text{Li}, \text{I}, \text{Aq}] = 46,100$ (*Th.* 3, 227). S. 151 at 0°, 164 at 19°, 179 at 40°, 200 at 59°, 263 at 75°, 435 at 80°, 476 at 99°, 688 at 120° (Kremers, *P.* 103, 65). By evaporating a solution of Li_2CO_3 in HIAq over H_2SO_4 , Ram-

meisberg obtained the hydrate LiHSO_4 (P. 66, 79).

Lithium oxide of Li_2O . Obtained by burning small quantities of Li, in a small iron vessel, in dry O_2 at 200° , cooling in O , and heating in the air to decompose Li peroxide (Troost, *A. Ch.* [3] 51, 103). Also prepared by heating Li_2CO_3 with C in a Pt crucible; and by heating LiNO_3 to redness in a Ag dish, best mixed with Cu turnings (H. Müller, *J. pr.* 58, 148).

A white crystalline solid; S.G. 2.102 at 15° (Brauner a. Watts, *P. M.* [5] 11, 60). Not decomposed by heating with C or Fe . Does not act on Pt at high temperatures; corrosion of the Pt vessel in the preparation of Li_2O indicates the presence of Rb_2O or Cs_2O . Reacts with Cl , S , and P . Heated in O , Li_2O is superficially changed to peroxide. Thomsen gives $[\text{Li}_2\text{O}, \text{Aq}] = 166,520$ (*Th.* 3, 227); and Beketoff (*B.* 41, 312) gives $[\text{Li}_2\text{O}, \text{Aq}] = 13,000$; hence $[\text{Li}_2\text{O}] = 153,520$.

Lithium peroxide is said to be formed by heating Li_2O or Li_2CO_3 for some time in air or O , but to be decomposed at a little above the temperature of formation.

Lithium phosphide of. According to Troost (*A. Ch.* [3] 51, 103) Li and P combine, when heated together, to form a brown substance which is decomposed by water with evolution of inflammable P hydride.

Lithium, silicofluoride of. $\text{Li}_2\text{SiF}_6 \cdot 2\text{H}_2\text{O}$. Transparent monoclinic crystals; obtained by adding H_2SiF_6 aq to Li acetate or carbonate, evaporating, treating the residue with water, filtering, and crystallising (Stolba, *J. pr.* 91, 456). S. 52.6 at ordinary temperature; sol. alcohol, insol. ether. S.G. 2.83. Dehydrated at 100° ; melts at a higher temperature with evolution of SiF_4 .

Lithium, salts of. Compounds produced by replacing H of acids by Li . The Li salts belong to one series Li_2X where $\text{X} = 2\text{Cl}, 2\text{NO}_3, \text{SO}_4, \text{CO}_3, \text{PO}_4$, &c.; they are generally obtained by dissolving Li_2CO_3 in the different acids, some are prepared by double decomposition from LiCl or Li_2SO_4 . Most of the salts of Li are sol. in water, but Li_3PO_4 and Li_2CO_3 are considerably less sol. than the corresponding salts of the other alkali metals; LiOH is also less soluble than the other alkalis (cf. ALKALIS, METALS OF THE, vol. i. p. 114). Few, if any, basic salts of Li are known. The chief Li salts are the following (v. CARBONATES, NITRATES, SULPHATES, &c.): *Antimonate, arsenate, borate, bromate, carbonate, chloride, chromate, dithionate, hypochlorite, hypophosphite, iodate, nitrate and -ite, perchlorate, periodate, phosphates, selenate and -ites, silicates, sulphates and -ite, tellurate and -ite, tri-arsenate.*

Lithium, sulphide of. Li_2S . Li and S combine when heated together; the solution in water is yellow from presence of polysulphides. Li_2S is obtained by reducing Li_2SO_4 by an equivalent quantity of C at full red heat; excess of C makes the product pyrophoric (Berzelius, *P.* 6, 439). Naudin a. Morfholon (*C. R.* 83, 58) say that Li_2S may be prepared by the long-continued passage of H_2S through Li_2CO_3 suspended in water. Li_2S is easily sol. water and alcohol. $[\text{Li}_2\text{S}, \text{S}, \text{Aq}] = 115,260$ (*Th.* 3, 227).

Lithium polysulphides are said to be obtained by melting LiOH with S (Vaquelin,

A. Ch. 7, 284); they closely resemble the polysulphides of the other alkali metals.

Lithium, sulphhydrate of; v. LITHIUM, HYDROSULPHIDE OF, p. 150. M. M. P. M.

LITHO-BILIIC ACID. $\text{C}_{12}\text{H}_{12}\text{O}_6$. [199°]. Occurs, together with lithofellic acid, in Oriental bezoar, and is prepared by decomposing the barium salt with hydrochloric acid and recrystallisation from alcohol. Long pale-yellow needles; insol. water, v. sol. alcohol, m. sol. ether. Its alcoholic solution is dextrorotatory. It resembles lithofellic and the biliary acids in its behaviour with Pettenkofer's reaction and its distillation products (Roster, *G.* 9, 462; Grattarola, *J.* 1880, 831).— BaA' , 6aq. Ppd. by adding BaCl_2 to a warm aqueous solution of crude sodium lithofellate; usually a yellowish semi-transparent resin; was obtained on one occasion in minute monoclinic crystals.

LITHOFELIC ACID $\text{C}_{12}\text{H}_{12}\text{O}_6$. [205°]. S. (alcohol) 3.4 at 20° ; 15 at 78° . S. (ether) .225 at 20° (Göbel). $[\alpha]_D = 13.8$ at 9.5° (independent of concentration). Forms the chief constituent of some kinds of Oriental bezoars (Göbel, *A.* 39, 237; Ettling, *A.* 39, 242; Wöhler, *A.* 41, 150; Heumann, *A.* 41, 303; Malaguti a. Sarzeau, *C. R.* 15, 518). The finely-powdered bezoars are extracted with boiling alcohol, and the solution evaporated. The crude acid then deposited is converted into sodium salt, and then into the Ba salt. On recrystallising, barium lithobilate remains undissolved, and the solution of barium lithofellate is then decomposed by HCl (Roster, *G.* 9, 364). Minute hexagonal crystals (containing aq) (Hoppe-Seyler, *Virchow's Arch.* 25, 528; Grattarola, *J.* 1880, 831). Insol. water. Dextrorotatory. Its salts are also dextrorotatory, somewhat bitter in taste. On distillation it gives off aromatic fumes.

Reactions.—1. When heated with sugar and H_2SO_4 it gives a crimson colour (Pettenkofer's reaction) (Strecker, *A.* 67, 53).—2. Boiling HCl aq resinifies it.—3. Hot nitric acid gives a yellow acid, $\text{C}_{12}\text{H}_{12}(\text{NO}_2)_6\text{O}_6$, which may be crystallised from HOAc .

Salts.—The sodium salt forms a pale-yellow gummy mass, exceedingly sol. water and alcohol. $[\alpha]_D = +18.16$ at 14.5° .— BaA' , 10aq: large prisms, sol. boiling water and alcohol. $[\alpha]_D = +19.7$ at 15° .— AgA' : flocculent pp.

LITHOSPERMUM ERYTHROHIZON (M. Kuhara, C. J. 35, 22). The Japanese prepare a dye called Shikon or Tokio purple from the root of this plant. The colouring matter may be extracted by exhausting successively with water and alcohol. Lead subacetate is added to the latter extract, and the purple pp. washed and decomposed by aqueous H_2S . The dye is extracted from the dried pp. by means of alcohol. It is resinous with green lustre. Its composition may be represented by $\text{C}_{20}\text{H}_{16}\text{O}_{10}$. Its alcoholic solution is purple, and shows an absorption spectrum similar to that of alkanet. Alkalis turn the solution blue; acids turn it red. Baryta gives a purple pp. $\text{C}_{20}\text{H}_{16}\text{BaO}_{10}$. The dye is readily oxidised to a brown scaly substance, $\text{C}_{20}\text{H}_{12}\text{O}_{10}$. Bromine forms a product of substitution, $\text{C}_{20}\text{H}_{12}\text{Br}_2\text{O}_{10}$. With PCl_5 it forms a black resinous body, $\text{C}_{20}\text{H}_8\text{Cl}_2\text{O}_{10}$.

LITHURIC ACID $\text{C}_{12}\text{H}_{12}\text{NO}_6$. (?) [205°]. Occurs as magnesium salt in some urinary

calculi of oxen (Rooster, *A.* 165, 104). Slender, silky needles. M. sol. boiling water and alcohol.— MgA' : minute monoclinic prisms; m. sol. boiling water, v. sl. sol. cold water, insoluble in alcohol.

LITMUS. Obtained chiefly from various species of *Roccella*, *Variolaria*, and *Lecanora*, the same lichens that yield archil. The blue colouring matter appears to be developed by fermentation after the mass has been treated with alkaline carbonate (Gélis, *Rev. Scient.* 6, 50; *J. Ph.* 24, 277).

When 2 pts. of *Roccella tinctoria* and 1 pt. of K_2CO_3 are repeatedly moistened with a solution of ammonium carbonate, the mass acquires a fine blue colour in forty days. The mass is then mixed with chalk and gypsum.

According to Kane (*T.* 1840, 298), litmus contains azolitmin, spaniolitmin, erythrolein, and erythrolitmin. Azolitmin is a reddish-brown amorphous powder, which dissolves in ammonia with blue colour, and forms blue and violet lakes. Spaniolitmin was not isolated by Kane, but appeared to be light red. According to Kane, erythrolein is a red viscid mass, forming a purple solution in ammonia, while erythrolitmin forms deep-red crystalline grains, forming a purple solution in ammonia. The method employed by Kane to isolate these substances is as follows: Litmus is exhausted with boiling water, the residue is acidified by HCl, again washed, and then boiled with alcohol. The alcoholic solution is evaporated to dryness, and the residue extracted with ether, which leaves erythrolitmin undissolved. The ether leaves erythrolein on evaporation. The reddish-brown powder left after boiling with alcohol is impure azolitmin.

De Luynes (*C. R.* 59, 49), by heating orcein with aqueous NH_3 and Na_2CO_3 at 70° , obtained a blue substance, which he regarded as the blue colouring matter of litmus.

According to Wartha (*B.* 9, 217), cold alcohol extracts from litmus a red substance, which is not affected by acids, and the residue yields to water the blue colouring matter. If the aqueous extract be evaporated, and the residue treated with absolute alcohol and some HOAc, a scarlet dye, turned purple by NH_3 , is extracted, while the residue is the pure litmus-blue, left as a brown powder.

A blue ethereal extract of litmus shows an absorption-band at D; a red ethereal extract shows an absorption-band extending to E (Vogel).

An aqueous solution of litmus, kept in a closed vessel, gradually becomes decolourised. This is due to the action of a micrococcus which reduces the colouring matter to a leuco-derivative, which is readily re-oxidised by air (Dubois, *Bl.* [2] 49, 963; cf. Bellamy, *J. Ph.* [5] 18, 488).

According to Förster (*Fr.* 28, 428), litmus is best purified by exhausting with alcohol in the cold, digesting with water, filtering, and evaporating. The residue is dissolved in water, filtered, and ppd. by a mixture of alcohol and HOAc. The pp. is washed with alcohol, and the solution, ppn., and washing repeated as long as any reddish-violet substance is removed thereby. The pp. is then dried, dissolved in water, the solution filtered and ppd. by feebly ammoniacal

alcohol. The pp. is finally washed with alcohol and dried.

LIVER OF SULPHUR. A name formerly applied to a mixture of the polysulphides of potassium, obtained by heating together K_2CO_3 and S in a closed vessel (v. POTASSIUM, SULPHIDES or).

LIXIVIATION. The application of water to solid mixtures, for the purpose of extracting the soluble parts.

LOBARIC ACID $C_{12}H_{10}O_4$. A resinoid acid obtained by extracting the lichen *Lobaria adusta* with ether (Knop, *C. C.* 1872, 172). Warty masses, made up of thin plates. Insol. water and baryta-water. In aqueous or alcoholic NH_3 it forms colourless solutions, which turn rose-red on exposure to air. KOHAq forms a yellow solution, turning brown on evaporation.

LOBELINE. An alkaloid existing in *Lobelia inflata* (Bastick & Procter, *Ph.* 10, 270, 456). Obtained by extracting the leaves with dilute acetic acid, and ppg. with magnesia. Thick, oily mass, decomposed by heat. V. sol. water, alcohol, and ether. Narcotic. Forms crystalline salts with HCl, HNO_3 , H_2SO_4 , and oxalic acid. Its solutions are ppd. by tannin.

Lobelia nicotianefolia contains also a second alkaloid, dissolved by $CHCl_3$ from solutions made alkaline by NH_3 . It resembles lobeline in physiological action, and, like it, exhibits no characteristic colour reactions (Dragendorff & von Rosen, *C. C.* 1886, 873).

LOGANIN $C_{12}H_{21}O_{11}$ [215°]. A glucoside found by Dunstan and Short (*Ph.* [3] 14, 1025) in the pulp in which the seeds of *Strychnos nuxvomica* are embedded. Extracted by alcohol-chloroform, and recrystallised from alcohol. Prisms. V. sol. water and alcohol, less sol. ether, $CHCl_3$, and benzene. The aqueous solution is not ppd. by reagents for alkaloids, nor by lead acetate or $AgNO_3$. Not coloured by $FeCl_3$, HNO_3 , or H_2SO_4 and $K_2Cr_2O_7$. Conc. H_2SO_4 gives a red colour on warming, changing to purple. Loganin does not reduce Fehling's solution. Boiling dilute H_2SO_4 splits it up into glucose and loganetin. Loganetin is sol. water and alcohol, less sol. ether and $CHCl_3$. It also gives a purple with H_2SO_4 .

LOKAONIC ACID $C_{12}H_{10}O_4$ (K.) or $C_{16}H_{18}O_8$ (C. a. G.) *Lokain*. The colouring matter of Chinese green, obtained from the berries of the buckthorn (*Rhamnus utilis*), contains lokaonic acid (Kayser, *B.* 18, 3417; cf. Cloëz & Guignet, *J.* 1872, 1068). Lokao, the commercial article, consists of calcium and aluminium lokaonates. It is decomposed by boiling with ammonium carbonate, and on adding alcohol to the filtrate ammonium lokaonate is ppd. This is decomposed by oxalic acid. Lokaonic acid is a deep-blue or bluish-black mass, which exhibits metallic lustre when rubbed. It is insol. water, alcohol, ether, and chloroform. In aqueous alkalis it forms a blue solution, changed to red by mild reducing agents, such as H_2S . Boiling dilute H_2SO_4 splits it up into a sugar, lokaose, and lokaonic acid.

Salts.— NH_4HA (at 100°): deep-blue pp., with bronze lustre when dry; sol. water, insol. alcohol.— $(NH_4)_2A$: similar to the preceding. Begins to lose NH_3 at 40° .— K_2A : dark-blue

powder.—BaA" (at 100°): deep-blue powder, insol. water.—PbA" (at 100°): blue-black pp.

Lokanic acid $C_9H_{10}O_6$ (K.) or $C_9H_8O_6$ (C. a. G.). *Lokagine*. Obtained by boiling lokaonic acid with dilute H_2SO_4 , dissolving the pp. in NH_4Aq , and ppg. with oxalic acid. Violet-black crystalline powder, which exhibits a bronze lustre when rubbed. Insol. water, alcohol, ether, and chloroform. Alkalis form a violet solution. At 120° it becomes $C_{10}H_{12}O_6$. Conc. H_2SO_4 dissolves it in the cold, and on adding water a reddish-brown powder, $C_{10}H_{12}O_6$, is ppd. This dissolves in NH_4Aq , and the solution gives, with $BaCl_2$, a reddish-brown pp., $BaC_{10}H_{12}O_6$. Lokanic acid is decomposed by boiling conc. KOHAq into phloroglucin and delokanic acid. Hot dilute nitric acid forms nitro-phloroglucin.

Salts.— NH_4HA (dried at 100°): bluish-black powder, sol. water, insol. alcohol. Dyes cotton, silk, and wool deep violet without mordant. Mixed with $Na_2S_2O_3$ it dyes cotton a permanent sky-blue (C. a. G.).—BaA" (dried at 100°): blue-black powder, insol. water and alcohol.—PbA": deep-blue powder, insol. water and alcohol.

Delokanic acid $C_9H_8O_6$. Formed as above. Brown powder, insol. water, sol. alcohol. Its solution in alkalis is cherry-red. It reduces Fehling's solution with difficulty in the cold.

Lokaose $C_9H_{12}O_6$. A sugar formed by hydrolysis of lokaonic acid. It reduces chloride of gold and Fehling's solution in the cold. It reduces H_2O as much CuO as glucose.

LOPHINE v. vol. i. p. 474.

LOTURINE. [234°]. Occurs to the extent of .24 p.c., together with .02 p.c. of colloturine and .06 p.c. of loturidine, in lotur bark from *Symplocos racemosa*, growing in India (Hesse, B. 11, 1542). The alkaloids are extracted from the bark by hot alcohol, and are converted into acetates. Loturine and colloturine are ppd. from the neutral solution by potassium sulphocyanide, leaving loturidine in solution. The crystalline pp. is decomposed by Na_2CO_3 , and the alkaloids are extracted with ether and recrystallised from alcohol. The efflorescent crystals of loturine are separated mechanically from the non-efflorescent crystals of colloturine.

Properties.—Long prisms. May be sublimed. Insol. water, sol. alcohol, acetone, ether, and chloroform. Its acid solutions exhibit violet fluorescence. It gives no colour with $FeCl_3$, conc. H_2SO_4 , HNO_3 , or bleaching powder followed by ammonia. Its hydrochloride forms white prisms. The hydrochloride, nitrate, and chromate crystallise in needles. The platinochloride is a yellow pp.

Colloturine. Long prisms; may be sublimed. Its solutions in aqueous HCl and H_2SO_4 fluoresce violet. Its aurochloride is a yellow amorphous pp.

Loturidine. Extracted from the filtrate from the ppd. sulphocyanides of loturine and colloturine by adding NH_3 and shaking with ether. Yellowish-brown amorphous mass. Forms amorphous salts. Its solutions in dilute mineral acids fluoresce violet.

LOXOPTERYGINE $C_{10}H_{12}N_2O_6$. [81°]. Occurs, together with another alkaloid and tannin, in red Quebracho bark from *Loxopterygium Lorentzii* (Hesse, A. 211, 274). Extracted by alcohol;

the alcoholic solution being evaporated, the residue treated with aqueous NaOH and the alkaloids extracted with ether. The acetic acid solution of the alkaloids is mixed with potassium sulphocyanide, which pptf. one alkaloid and leaves the loxopteryrine in solution, whence it is ppd. by ammonia. White amorphous mass, sl. sol. cold water, v. sol. alcohol, ether, chloroform, and benzene. Its solutions exhibit alkaline reaction. Tastes intensely bitter. Conc. H_2SO_4 and a little $K_2Cr_2O_7$ gives a violet colour.

LUPANINE $C_{15}H_{21}N_2O$. Occurs in the seeds of the blue lupine (*Lupinus angustifolius*), from which it is extracted by alcohol containing HCl (Hagen, A. 230, 370). Viscid yellow liquid with green fluorescence, characteristic smell, and very bitter taste. Sl. sol. water, but separates on warming; m. sol. cold alcohol, v. sol. ether and chloroform. Not volatile with steam. Strongly alkaline, fuming with HCl.

Salts.—B'HCl 2aq. [127°]. M. sol. water and alcohol, insol. ether. The base is set free from this salt by KOH (but not by NH_3).—B'HI 1½aq: yellow crystals (from hot water), sol. CS_2 , insol. alcohol and ether.—B'HCyS ¼aq: pale yellow crystals; v. sol. hot alcohol, sl. sol. water, insol. ether.—B'HPtCl₄ 3¼aq.—B'HAuCl₄: splendid yellow needles, sl. sol. ether, insol. water and alcohol.

Methylo-iodide B'MeI. [215°]. Crystals, sl. sol. water, insol. alcohol and ether. The methylo-hydroxide is formed by treatment with Ag_2O but not with KOH.

Methylo-chloride B'MeCl 2aq. [128°]. Extremely deliquescent crystals, insol. ether.—B'MeHPtCl₄ ¼aq: red crystals, insol. ether, sl. sol. alcohol.—B'MeAuCl₄ ¼AuCl₄: lemon-yellow needles.

LUPETIDINE v. DI-METHYL-PYRIDINE HEXA-HYDRIDE.

LUPINIDINE v. LUPININE.

LUPININ $C_{20}H_{29}O_{10}$. *Lupinin*. A glucoside in the buds of the yellow lupine (*Lupinus luteus*). Extracted by 50 p.c. alcohol (Schulze a. Barbieri, B. 11, 2200). Slender yellowish-white needles (containing 7aq). Sl. sol. water and alcohol. Alkalis form a deep yellow solution. Its ammoniacal solution gives a lemon-yellow pp. with lead acetate. Boiling with water or dilute acids splits it up into glucose and lupigenin.

Lupigenin $C_{11}H_{15}O_9$. Formed as above. Minute yellow needles, insol. water, sl. sol. alcohol. Forms a deep-yellow solution in aqueous NH_3 .— NH_4A' ¼aq: lemon-yellow powder.

LUPININE $C_{21}H_{29}N_2O_9$. [68°]. (256°). An alkaloid in the seeds of the yellow lupine (*Lupinus luteus*), and extracted by alcohol containing HCl. The extract is evaporated to a syrup, treated with KOH, and shaken with light petroleum. The petroleum is shaken with aqueous HCl, the solution treated with KOH, and the alkaloid extracted by ether, from which it is recrystallised (Baumert, J. V. 27, 15; cf. Beyer, L. V. 14, 161; v. also lupinidine, *infra*).

Properties.—Trimetric crystals, may be distilled in a current of hydrogen. Tastes bitter. V. sol. cold water and alcohol, less sol. hot water; v. sol. benzene, chloroform, and CS_2 . Strong base; liberating NH_3 from its salts and fuming with HCl. In its solutions tannin gives a flocculent pp.; phospho-molybdic and phos-

photungstic acids give yellow pps.; iodine gives a dirty brownish-red pp.

Reactions.—1. HI gives $C_{12}H_{19}N_3O_4I_2$.—2. With fuming HCl at 200° it forms anhydro-lupinine $C_{12}H_{15}N_3O$ and finally di-anhydro-lupinine $C_{12}H_{11}N_3$ (Baumert, A. 214, 366).—3. P_2O_5 heated with the hydrochloride at 180° forms oxy-lupinine, which with platinic chloride forms $C_{12}H_{15}N_3O_4PtCl_6$ crystallising in yellow plates. If the mother-liquor be heated with P_2O_5 to a higher temperature anhydro-lupinine is formed (Baumert, A. 214, 366).—4. Sodium dissolves in fused lupinine, but the product is decomposed by water into NaOH and lupinine (Baumert, B. 15, 631).

Salts.— $B''H_2Cl_2$: large trimetric crystals.— $B''2HNO_3$: crystals, v. e. sol. water and alcohol.— $B''H_2SO_4$: deliquescent prisms.— $B''(HAuCl_4)_2$: needles, v. sl. sol. water.— $B''H_2PtCl_6$: crystals, sol. water.

Acetyl derivative $C_{12}H_{15}Ac_2N_3O_2$. Obtained by heating lupinine with $AcCl$ or with Ac_2O and NaOAc (Baumert, A. 224, 313). Oil.— $B''H_2PtCl_6$: orange trimetric plates.

Methylo-iodide $B''Me_2I_2$: white hexagonal plates; sl. sol. alcohol (Baumert, B. 14, 1221).

Methylo-chloride $B''Me_2Cl_2$: pearly plates.— $B''Me_2PtCl_6$: orange-red needles.— $B''Me_2AuCl_4$: yellow pp.

Ethylo-iodide $B''EtI_2$: hexagonal plates (Baumert, B. 14, 1321). Decomposed by Ag_2O , but not by KOH. From it may be obtained $B''EtPtCl_6$ and $B''(EtAuCl_4)_2$ [70°].

Anhydro-lupinine $C_{12}H_{15}N_3O$. Formed by heating lupinine with fuming HCl at 150°–200° (Liebscher, B. 14, 1880). Liquid which cannot be distilled. Oxidised by air. Smells like cocaine. Forms crystalline salts.— $B''H_2PtCl_6$: red scales, v. sol. water.

Di-anhydro-lupinine $C_{12}H_{11}N_3$ (220°). From lupinine and conc. $HClAq$ at 200° (Liebscher a. Baumert, A. 214, 371). Oil. Readily oxidised by air.— $B''H_2PtCl_6$: dark-red crystals; v. sol. warm water.

Lupinidine $C_{12}H_{13}N$.

Preparation.—Lupine seeds are extracted with dilute alcohol acidified with H_2SO_4 , and, after as much fat as possible has been removed, the sulphate solution is evaporated to a syrup and the residue triturated with absolute alcohol, when it solidifies to a mass of crystalline plates. This mass is again triturated with absolute alcohol, when a white crystalline meal of acid lupinidine sulphate separates. The mother-liquors are treated again in the same manner, until the residue, on trituration with alcohol, either remains liquid or at least redissolves off washing with absolute alcohol; in this case it consists for the most part of lupinine sulphate. The mother-liquors containing the lupinine sulphate are freed from alcohol, dissolved in water, and p.p.d. by $BaCl_2$. The filtrate now contains chiefly lupinine chloride, from which any lupinidine salt present can be p.p.d. as platino-chloride (G. Baumert, A. 225, 365). Lupinidine is obtained by decomposing the acid sulphate by one of the stronger bases, shaking with ether, and distilling in a current of hydrogen. The fact that this alkaloid distils over in a stream of hydrogen, between the wide limits of 250°–320°,

is explicable on the assumption that the lupinidine got from the seeds of the yellow lupine is a mixture of crystallisable hydrate (see below) and a liquid anhydride. The formula $C_{12}H_{13}N$ is calculated from analyses of its salts.

Properties.—Thick yellow oil of intensely bitter taste and disagreeable hemlock-like smell; but this smell is probably due to a decomposition product. Strong base. Very easily oxidisable by the air when in contact with acids or with $KOHAq$, but not with NH_4Aq . Gives no acetyl derivative or ethylo-iodide (Baumert, A. 225, 365). Lupidine is a feeble poison, acting on frogs like curare (Kobert, A. 227, 219).

Salts.— $B''HCl$: yellow deliquescent crystals.— $B''HI$: rather large crystals resembling alum, v. sol. hot water, m. sol. alcohol.— $B''2HI(?)$ Formed by heating lupinidine with EtI . Thus lupinidine resembles berberine in giving a hydro-iodide when heated with EtI (Baumert, A. 227, 207).— $B''H_2SO_4$: minute crystals, v. e. sol. water, v. sl. sol. alcohol.— $B''H_2PtCl_6$: 2aq: trimetric crystals, $a:b:c = 885:1:171$ (Luedecke, Z. K. 12, 297), sl. sol. water, m. sol. $HClAq$, v. sol. dilute alcohol (Baumert, A. 225, 365).

Hydrate $C_{12}H_{15}Naq?$ The liquid and crystalline portions of the lupine alkaloid are to be considered as modifications of the same base (the hydrate being crystalline), since both yield the same double salt with $PtCl_6$. The existence of a hydrate, stable only in the cold, may also explain why cold aqueous solutions of lupinidine, lupinine, and conine become milky on heating. A further proof of the correctness of this view is that the yellow oil only (probably the pure anhydride $C_{12}H_{13}N$) was got on treating the lupinidine with P_2O_5 (Baumert).

Lupinine. A crystalline alkaloid, called by this name, was obtained by Betelli (G. 11, 240) by extracting white lupine (*Lupinus albus*) with alcohol. It forms white needles, v. sol. water. An alcoholic extract of the plant has been used with some success in cases of intermittent malarial fever. Solutions of the alkaloid give white pps. with tannin, $HgCl_2$, and $AgNO_3$, in the last case reduction soon takes place. Platinic and gold chlorides and picric acid give canary-yellow pps. $HIAq$ containing iodine gives a red amorphous pp. It does not reduce Fehling's solution. Boiling KOH gives off ammonia.

Lupinine. A liquid alkaloid, also called lupinine, was obtained by Campani (G. 11, 237) from the white lupine. It boiled between 210° and 218° and was poisonous.

The young shoots of the yellow lupine contain an alkaloid called *ANANIN* (q. v.). The danger to sheep from eating lupines appears to be due to another substance 'icterogen,' perhaps produced by a parasite growing on the lupines (Baumert, Ar. Ph. [3] 24, 49; Kobert a. Liebscher, J. 1886, 1696; Kühn, *ibid.*).

LUPULIN. The yellow granular aromatic powder situate at the base of the cones of the hop and forming from 8 to 18 p.c. of the cones. It contains hop oil, a resin, a nitrogenous substance, a gummy substance, and a bitter principle. Lerner (D. P. J. 179, 54) extracted the bitter principle by ether, shook the ether with aqueous KOH, p.p.d. by $CuSO_4$, decomposed the copper compound with H_2S , and recrystallised from ether. He describes

the 'lupulin' so obtained as large white prisms, insol. water, v. sol. alcohol, ether, and chloroform. The alcoholic solution, diluted with water, had a bitter taste and acid reaction. Lerner also obtained a compound [110°] which likewise formed a copper salt. Lupulic acid, as described by Bungener, appears to be Lerner's lupulin. Issleib (*Ar. Ph.* [3] 16, 845) found a 'pseudo-glucoside' $C_{22}H_{34}O_{10}$, which he extracted by cold water. The extract was treated with animal charcoal, the charcoal dried and exhausted with 90 p.c. alcohol, and the yellow solution partially evaporated. A brown resin $C_{10}H_{16}O_2$ is deposited while a bitter uncrystallisable substance remains in solution. From the aqueous solution of this bitter substance other extracts only the bitter principle (which amounts to .004 of the hops) and leaves in the water $C_{10}H_{16}O_2$, a tasteless product of the oxidation of oil of hops $C_{10}H_{16}O$. The bitter principle, according to Issleib, forms a yellow solution in alkalis, and is split up by boiling dilute H_2SO_4 into lupuliretin $C_{10}H_{16}O_4$ and lupulic acid $C_{10}H_{16}O_{11}$. This lupulic acid forms a crystalline barium salt $BaC_{10}H_{16}O_{11}$, 6aq. According to Bissell (*Ph.* [3] 8, 508) lupulin does not contain all the active principle of the hop. The bitter principle may usually, but not always, be ppd. from an infusion of hops by lead acetate (Allen, *An.* 18, 43). According to Hayduck (*C. C.* 1887, 694), when hops are exhausted with ether, and after evaporating the ether, the residue is treated with alcohol, a white wax is left behind. The alcoholic solution gives a yellow pp. with lead acetate, and the filtrate contains two resins, one soluble, and the other insoluble, in light petroleum.

Lupulic acid $C_{10}H_{16}O_{11}$, [93°].

Preparation.—By extracting hop-flour with light petroleum spirit, distilling off the solvent, cooling, filtering off the black liquid from the crystals formed, and recrystallising the crude acid from alcohol and petroleum spirit.

Properties.—Colourless prismatic crystals, rapidly altered by exposure to the air. V. sol. alcohol, ether, benzene, $CHCl_3$, CS_2 , and the ethereal oil of the hop, sol. petroleum spirit, insol. water. Easily reduces ammoniacal $AgNO_3$. Exposed to the air is transformed into a yellowish resin. This product of oxidation is sl. sol. water, to which it imparts an intense bitter taste, and this resin is the bitter principle of the hop.— CuA' . A crystalline powder (Bungener, *Bl.* [2] 45, 487).

LUPULINE v. HOPELINE.

LUTEIC ACID $C_{20}H_{30}O_6$ (?). [274°]. S. .009 in the cold; .03 at 100°. S. (alcohol) 4.2 in the cold. S. (ether) .37. A yellow colouring matter prepared from the flowers of *Euphorbia cyparissias* (Höhn, *Ar. Ph.* [2] 140, 218). The fresh flowers are exhausted with alcohol of 60 p.c., the greater part of the alcohol distilled off, and the residual liquid filtered and ppd. with basic lead acetate. The pp. is suspended in water, decomposed by H_2S , and filtered. The filtrate is evaporated over H_2SO_4 , and the yellowish crusts that separate are recrystallised from ether-alcohol, and then from hot water containing 4 p.c. of alcohol. Slender yellow needles. Has no smell and a bitter taste. Sublimes at 220°. Its solutions exhibit acid reaction. Lutein somewhat resembles luteolin and,

like the latter, gives protocatechuic acid by potash-fusion. It dissolves in caustic and carbonated alkalis forming yellow solutions. It reduces $AgNO_3$, mercurous nitrate, and Fehling's solution on heating. $FeCl_3$ gives a green colour, changing to reddish-brown on further addition of $FeCl_3$. Conc. H_2SO_4 dissolves luteic acid, but water reprecipitates it unaltered. Boiling dilute H_2SO_4 does not attack it.

LUTEIN. This name is given by Thudichum (*Pr.* 17, 253) to the yellow substance obtained by Piccoli and Lieben (*Z.* 1868, 645) from the ovary of the cow, and called by them 'haemolutein' (cf. Holm, *Z.* 1867, 779). It occurs also in the human ovary. The same or a similar substance occurs in butter, yolk of egg, serum of blood, in some diseased swellings, in carrots, &c. It occurs also in the retina of the eyes of fowls (Capranica, *J. Th.* 1877, 317; Kühne, *J. Th.* 1877, 317). According to Maly (*C. C.* 1881, 485; *M.* 2, 359), the lutein in yolk of egg of hens and shrimps is a mixture of vitello-lutein and vitello-rubin. If the yolk is extracted with alcohol, and the extract treated with hot baryta-water, vitellorubin is ppd. while vitellolutein remains in solution. Or the yolk extract may be boiled with a little acid, and the ppd. albumen treated with petroleum which extracts vitellolutein, while CS_2 extracts vitellorubin from the residue. Vitellorubin contains no nitrogen. It is red, and forms a Mg compound sol. ether, chloroform, and CS_2 , but ppd. by alcohol in red flakes. An alcoholic solution of vitellorubin shows a broad but weak absorption band including the line F. Vitellolutein forms a yellow alcoholic solution which exhibits two narrow absorption bands, one including F, the other between F and G. It contains no nitrogen.

LUTEOCHROMIUM SALTS; v. vol. ii. p. 160.

LUTEOCOBALTIC SALTS; v. vol. ii. p. 228.

LUTEOLIN $C_{20}H_{30}O_6$ (Moldenhauer, *A.* 100, 180) or $(C_{12}H_{16}O_2)_2$, 3aq (Schützenberger & Paraf, *A. Suppl.* 1, 256). [320°]. S. .007 in the cold, .02 at 100°. S. (alcohol) 2.7. S. (ether) .16. The yellow colouring matter of weld (*Reseda luteola*) (Chevreul, *J. Chim. Méd.* 6, 157). Obtained by boiling weld with water (16 pts.) mixed with alcohol (1 pt.), filtering, evaporating, dissolving the yellow flakes in alcohol, and pouring into water. It is recrystallised from a mixture of water and glycerine (Rochleder, *J. pr.* 99, 433). Yellow, four-sided needles in radiate groups. May be sublimed. Partially decomposed on fusing. Has a slightly bitter, astringent taste. Reddens litmus slightly. Dissolves with deep yellow colour in caustic and carbonated alkalis. Conc. H_2SO_4 forms a yellow solution, whence water reprecipitates it. Potash-fusion gives CO_2 , phloroglucin, and protocatechuic acid. Very dilute $FeCl_3$ gives a green pp., excess of $FeCl_3$ forms a brownish-red solution. Alcoholic lead acetate gives a pp. $C_{12}H_{16}PbO_4$ aq.

(β)-**LUTIDINE** C_8H_9N . *Et. yl-pyridine* (?). Mol. w. 107. (166°). S.G. 2 .956 (W.); .959 (C.). V.D. 8.79 (calc. 8.70). S. 4 (W.). Obtained, together with homologues, by distilling cinchonine with KOH; a mixture of some ten bases is obtained and these are separated by fractional distillation (Greville Williams, *J.*

LUTIDINE

1855, 549; 1864, 437; *Pr.* 13, 805; Oechsner de Coninck, *C. R.* 92, 413; *Bl.* [2] 35, 296; *R. T. C.* 1, 132; *A. Ch.* [5] 27, 462, 488). The same base appears to be formed by distilling with zinc-dust the syrupy acid formed by oxidising cinchonine with chromic acid mixture (Wiedel a. Hazuka, *M.* 3, 780). This, or an isomeric ethyl-pyridine, is formed by distilling brucine with KOH (O. de Coninck, *Bl.* [2] 42, 100). Liquid; sl. sol. water, sol. alcohol and ether. The aqueous solution does not become turbid on warming, the base being more soluble in hot than in cold water. It appears to form an unstable hydrate $C_8H_{10}NH_2O$. Smells somewhat like nicotine. Physiologically it is a violent poison and stops tetanus produced by strychnine (Greville Williams a. Waters, *Pr.* 32, 162). By chromic acid mixture or by $KMnO_4$ it is oxidised to pyridine carboxylic (nicotinic) acid [231°]. When heated with sodium it appears to form di-(β)-lutidine $C_{16}H_{20}N_2$ (Greville Williams, *Pr.* 33, 159). Chlorine passed into (β)-lutidine containing dissolved iodine appears to form tri-chloro-(β)-lutidine. Chloroacetic acid gives $C_8H_7NClCH_2CO_2H$ (163°) forming ($C_8H_7NO_2Cl$) $_2PtCl_2$ 2aq (Piclet, *J.* 1882, 1079).

Salts.— $B'HCl$. Very deliquescent crystals. — $B'HBr$. — $B'_2H_2PtCl_2$: orange-red leaflets. Its ppn. is not retarded by presence of excess of HCl (difference from bone oil lutidine). Hot water decomposes it forming B'_2PtCl_2 , crystallising in pale-yellow leaflets. — B'_2PtCl_2 . From platinum chloride (1 pt.) and lutidine (1 pt.): combination takes place with rise in temperature (of 70°), the product being a hard brittle mass (Williams). — $B'HAuCl_4$. Yellow pp. On boiling with water it forms yellow B'_2HAuCl_4 and ultimately B'_2AuCl_4 : a red crystalline powder. — $B'_2H_2PdCl_4$: garnet-red prisms, obtained by mixing solutions of the hydrochloride and of palladium chloride (W.). Decomposed at 100°, giving off HCl and leaving B'_2PdCl_4 , sl. sol. water. — $B'_2H_2Cl_4U_2O_7$. Formed from uranyl chloride and (β)-lutidine hydrochloride. Yellow. — $B'_2H_2SO_4(UO_2)_2(SO_4)_2$. From uranyl sulphate and (β)-lutidine sulphate. Small yellow needles. —Picrate $B'C_6H_3(NO_2)_3OH$. Yellow needles (Williams, *Pr.* 33, 159).

Combinations.— B'_2CuSO_4 4aq. When (β)-lutidine is added to a solution of cupric sulphate a copious pale-green pp. is formed, which dissolves in excess, forming a rich-blue liquid, which deposits blue prisms of B'_2CuSO_4 4aq. — B'_2AgNO_3 . Formed by ppn. silver nitrate solution with (β)-lutidine and recrystallising from alcohol.

Di-(β)-lutidine. When sodium is warmed with (β)-lutidine dissolved in toluene a product is obtained from which it is possible to get a platinumchloride containing a percentage of platinum corresponding to the formula $C_{16}H_{20}N_2HPtCl_4$ (Williams, *C. N.* 44, 308).

Tetra-(β)-lutidine. When sodium is warmed with (β)-lutidine a violent action takes place, and from the product a platinumchloride may be obtained containing a percentage of platinum corresponding to the formula $C_{32}H_{40}N_4HPtCl_4$ (Williams).

Hydride of (β)-lutidine C_8H_7N . Greville Williams found that sodium-amalgam had no

action on (β)-lutidine. According to Oechsner de Coninck (*Bl.* [2] 42, 121), however, a hexahydride (155°–160°) may be formed by the action of sodium on an alcoholic solution of the base (cf. Wyschnegradsky, *B.* 13, 2401). It combines with Mel and the product, when distilled with KOH , yields C_8H_7N (160°). It also combines with EtI , and the product treated with potash yields a tertiary base boiling at 175°.

Lutidine C_8H_7N . (173°). Obtained by distilling strychnine with zinc-dust (Seichlioni a. Magnanini, *C.* 12, 445). Yellow liquid, insol. water, sol. alcohol and ether. Smells like pyridine. Gives with sodium phosphomolybdate a dark yellow pp., sol. ammonia. Potassio-mercuric iodide gives a yellow amorphous pp. Mercuric chloride gives a white pp. Iodine in $KIAq$ gives a crimson pp., insol. dilute $HClAq$. Coal tar lutidines v. DI-METHYL-PYRIDINE.

Isomerides v. ETHYL-PYRIDINE and DI-METHYL-PYRIDINE.

LUTIDINE CARBOXYLIC ACIDS v. DI-METHYL-PYRIDINE CARBOXYLIC ACID.

LUTIDINIC ACID v. PYRIDINE-DI-CARBOXYLIC ACID.

LUTIDONE v. OXY-DI-METHYL-PYRIDINE.

LUTIDO-STYRIL v. OXY-DI-METHYL-PYRIDINE.

LUTIDYL-QUINOLINE v. DI-METHYL-PYRIDYL-QUINOLINE.

LYCACONITINE v. ACONITE ALKALOIDS.

LYCINE. The base from *Lycium barbarum* to which this name was applied has been shown to be identical with betaine.

LYCOPODINE $C_8H_7N_2O_2$. [115°]. Occurs in *Lycopodium complanatum* (club moss), from which it is obtained by extracting the root with alcohol, evaporating the extract, dissolving the residue in water, adding lead subacetate, removing excess of lead by H_2S , adding $NaOH$, and shaking with ether. When the ether is evaporated the alkaloid is left, and may be purified by dissolving in $HClAq$ and ppn. with conc. $NaOHAq$ (Bödeker, *A.* 208, 363). Monoclinic prisms, v. sol. most menstrua. Tastes bitter. — $B'HI_2$ 2aq: glassy hexagonal crystals (Söfling, *J.* 1884, 463). — $B''(HAuCl_4)_2$ 2aq: small glistening yellow needles.

LYCOPODIUM BITTER. The alcoholic and aqueous extracts of *Lycopodium chamaecyparissus* are evaporated, and the residues mixed and extracted with water. The solution is treated with lead acetate and subacetate, filtered, freed from lead by H_2S and evaporated. The residue is then washed with alcohol and dissolved in water. From this solution lead subacetate ppt. the bitter principle, and the pp. is then suspended in water and decomposed by H_2S . The filtrate is concentrated, freed from sugar by careful fermentation with yeast, dried, and extracted with absolute alcohol, which leaves the bitter principle on evaporation (Kamp, *A.* 100, 380). Slender needles (from water). v. e. sol. water, alcohol, and ether. Extremely bitter. Neutral to litmus. Contains no nitrogen. Colours tincture of iodine orange-red. Does not reduce Fehling's solution, but after boiling with dilute H_2SO_4 it does so.

LYCOPODIUM OIL. The oil from the fresh spores of club moss contains phytosterin $C_{27}H_{48}O$, together with glyceryl ethers of lycopodine

$C_{15}H_{31}O_2$, oleic, arachic, stearic, and palmitic acids (Bukowski, *Chem. Zeit.* 1889, 174; cf. Langer, *Ar. Ph.* [8] 27, 625).

LYCOPESIN $C_{15}H_{31}O_2$. [170°]. Extracted from *Lycopodium Chamæcyparissus* by alcohol, and remaining in the mother-liquor after lycostearone has separated (Kamp, A. 100, 300). Minute crystals; almost insol. boiling water, v. sol. alcohol and ether, v. sl. sol. cold alkalis.

LYCOSTEARONE $C_{15}H_{31}O_2$. [75°-100°]. An amorphous tasteless substance, which may be extracted by alcohol from *Lycopodium chamæcyparissus* (Kamp, A. 100, 300). Insol. cold water, sol. hot water forming a jelly on cooling. Sl. sol. cold alcohol and ether, v. sol. alkalis.

LYDINE. A violet dye obtained by pouring a solution of aniline (100 g.) in fuming $HClAg$ (100 g.) diluted with water (120 c.c.) into a solution of K_2FeCy_6 (90 g.) in water (850 c.c.), and heating the mixture to boiling. The product is dissolved in dilute oxalic acid and ppd. by alkalis. Violet powder, sol. alcohol, sl. sol. ether and benzene, insol. water. Poisonous (Guyot, C. R. 69, 829). Possibly identical with mauvine.

M

MACLEYIN $C_{20}H_{31}NO_3$ (?). [201°]. S. ($CHCl_3$). 7. S. (ether) 1. An alkaloid in *Macleya cordata*, the Japanese *Tachibakau* (Eijkman, R. T. C. 3, 182; *Ph.* [3] 13, 87). Extracted from the root by alcohol and dilute H_2SO_4 , and separated from sanguinarin by ether in which it is very slightly soluble. Prisms. Almost insol. water and alkalis, v. sl. sol. hot alcohol. Its salts have a bitter taste. Its chemical properties resemble those of protopine. Conc. H_2SO_4 gives a faint yellow changing through violet to green. Fumes of nitric acid give an ultramarine colour. H_2SO_4 and a little $K_2Cr_2O_7$ give a blue colour.

Salts.— $BHCl$. Prisms. S. 7. — $B_2H_2PtCl_6 \cdot 2aq$: yellowish-white pp. — $B_2H_2Cr_2O_7$: orange prisms. — Hydroiodide: crystalline spheres. — Normal sulphate: colourless needles. — Thiocyanate: needles. — Acetate: needles. — Acid oxalate: crystals. — Acid tartrate: needles. — Benzoate: [166°]: long needles.

MACLEURIN $C_{13}H_{19}O_4$ (H. a. P.); $C_{13}H_{19}O_4$ (L.). *Morintarnic acid*. [200°] (Wagner). S. 52 at 14°. Occurs, together with morin (*q. v.*), in old fustic, the wood of *Morus tinctoria*, from which it is obtained by extracting with water. The evaporated extract deposits morin, and from the filtrate maclurin may be ppd. by HCl (Hlasiwetz a. Pfaunder, A. 127, 352; *J. pr.* 94, 65; Löwe, *Fr.* 14, 117; Benedikt, A. 185, 114). Almost pure maclurin is also found in patches in the wood (Wagner, J. 1850, 529).

Properties.—Yellow, crystalline powder (containing aq.), v. sol. alcohol and ether, sl. sol. water. Above 270° it gives CO_2 and pyrocatechin. Its aqueous solution is ppd. by alkaloids, gelatin, and albumen. $FeSO_4$ gives a greenish-black pp. Its alkaline solution turns brown in air. It dyes mordanted cotton pale brownish-yellow. Boiling conc. KOH aq. gives phloroglucin and protocatechuic acid: $C_{13}H_{19}O_4 + H_2O = C_6H_3O_3 + C_7H_5O_4$. Dilute H_2SO_4 at 120° does the same. Bromine gives tri-bromo-maclurin $C_{13}H_5Br_3O_4$ aq.: minute needles. Conc. H_2SO_4 at 190° gives brown $C_{13}H_{11}O_4$ (Hlasiwetz, A. 143, 308). Reduction with zinc and H_2SO_4 gives phloroglucin and machronin. When its solution is heated with sodium-amalgam and the product acidified, ether extracts phloroglucin and amorphous $C_{13}H_{15}O_4$, which is sol. water and alcohol, is ppd. by lead acetate, gives a grass-green colour with $FeCl_3$, and reduces $AgNO_3$ and Fehling's solution.

Salts.— $PbC_{13}H_{19}O_4$ aq.: yellow crystals. — $C_{13}H_{19}O_4 \cdot 3PbO$ (L.).

Acetyl derivative $C_{13}H_{17}AcO_4$ 14aq.: viscid oil.

Machronin $C_{13}H_{19}O_4$ 3aq (?). Formed by the action of zinc and dilute H_2SO_4 on maclurin, and separated from phloroglucin by ppn. with lead acetate. The pp. is decomposed by H_2S . Colourless spangles composed of tufts of minute needles (from dilute alcohol). V. sl. sol. water and alcohol, m. sol. ether. Turns dark blue when exposed to air or when heated. The hot aqueous solution turns violet-blue in air, and then yields an indigo-blue pp. with HCl . $FeCl_3$ gives, in a very dilute alcoholic solution, a violet-red colour, changing to blue. Alkaline solutions also turn blue on exposure to air. $AgNO_3$ gives a violet colour with reduction of silver. Reduces hot Fehling's solution. Conc. H_2SO_4 gives an orange solution, turning emerald green on warming or diluting.

Rufimoric acid $C_{13}H_{19}O_4$ (?). Obtained by boiling maclurin with dilute HCl (Wagner, J. 1851, 420). Dark-red mass; v. sol. alcohol, m. sol. water, v. sl. sol. ether. Forms a crimson solution in alkalis.

MACROCARPINE v. THALICTRINE.

MADDER v. OXYANTHRAQUINONES.

MAGDALA RED $C_{20}H_{21}N_3Cl$. Formed by heating naphthalene-azo-(α)-naphthylamine with (α)-naphthylamine hydrochloride (Hofmann, B. 2, 374, 412). Appears to be a compound of amido-

naphthazine $C_{10}H_7(NH_2)_2$  $C_{10}H_7$, allied to saf-
franine, viz.:

$C_{10}H_7(NH_2)_2$  $C_{10}H_7$ (Julius, J. 19, 1365).

MAGNESIA. *Magnesium oxide* MgO (*q. v.*

MAGNESIA ALBA. A basic carbonate of Mg , varying somewhat in composition; v. CAL-
CINATES, vol. i. p. 699.

MAGNESIA USTA. A name given in pharmaceutical nomenclature to MgO prepared by calcining *magnesia alba*.

MAGNESIUM. At. w. 24. Mol. w. probably same as at. w. (*v. infra*). [c. 450°] (Deville a. Caro, A. 101, 359); [c. 500°] (Ditte, C. R. 78, 108) [between 700° and 800°] (V. Meyer, B. 20, 497). Scarcely volatilises in CO at red to white heat (V. M. &c.). S.G. 1.69 to 1.71 at 17° (Kopp)

1.77 at 0° (Wurtz, *Am. Ch.* 1876 (March)). S.H. 20° to 51° 245 (Kopp, *T.* 155, [1] 71). C.E. at 43° 00002694 (Fizeau, *C. R.* 68, 1125). T.C. (Ag = 100) 34.3 (Lorenz, *W.* 13, 422). E.C. (Hg at 0° = 1) 22.84 at 0°, 16.34 at 100° (Lorenz, *W.* 13, 422, 582). S.V.S. c. 14.1. Characteristic lines in emission-spectrum 5527.4, 5183, 5172, 5166.7 (Thalén, Upsala, 1868; v. also Liveing & Dewar, *Pr.* 44, 241).

Occurrence.—The metal does not occur native, but compounds of Mg are very widely distributed, and are found in some places in large quantities; they usually accompany Ca compounds. *Magnesite* $MgCO_3$, *dolomite* a mixture of the isomorphous carbonates of Mg and Ca, *kieserite* $MgSO_4 \cdot H_2O$, *carnallite* $MgCl_2 \cdot 6H_2O$, various silicates e.g. *asbestos* $(MgCa)SiO_3$, *spinel* $MgAl_2O_3$, &c., occur as minerals. Borate, phosphate, sulphate, chloride, nitrate, and hydroxide, of Mg are found in mineral waters, and some of them in sea water; Mg compounds, chiefly phosphate and carbonate and compounds of organic acids, are found in plants and animals.

Magnesia alba (a basic carbonate of Mg) was introduced as a medicine in the beginning of the 18th century; the name is said to have been given merely in contradistinction to *magnesia nigra*, a term applied to the mineral pyrolusite because of its colour and supposed magnetic properties. Magnesia was long supposed to be the same, or nearly the same, as lime. Hoffmann, Bergmann, Marggraf, and especially Black (1755) established the characteristic properties of magnesia. Black showed *magnesia alba* to be a compound of fixed air (CO_2) with an earthy base, to this base he gave the name magnesia. In 1800 Davy obtained a small quantity of a metal by reducing magnesia at white heat by vapour of K; in 1830 Bussy obtained the metal in greater quantity and purity, by heating together $MgCl_2$ and K.

Formation.—1. By heating together $MgCl_2$ and K in a Pt crucible, and washing out KCl by water (Bussy; Buff, *P.* 18, 140; Liebig, *P.* 19, 137).—2. By electrolysis fused $MgCl_2$ (Bunsen, *A.* 82, 187), or a mixture of $MgCl_2$ and KCl with a little NH_4Cl (Matthiessen, *C. J.* 8, 107).—3. By reducing a molten mixture of $MgCl_2$, CaF_2 , KCl, and NaCl, by Na (Deville a. Caron, *C. C.* 1863, 993).—4. By reducing MgF_2 , NaF by Na (Tissier, *C. R.* 56, 848).—5. By electrolysis a mixture of $MgSO_4$ and $(NH_4)_2SO_4$ dissolved in water (Gerhard, *English Patents*, No. 16,691; 1884).—6. Puettner patented a method for reducing $MgCO_3$ by heating with Fe_2O_3 and C (*German Patents*, No. 31,319).—7. Lauterborn reduces a double Mg-Na cyanide by Zn (*German Patents*, No. 39,915).

Preparation.—1. The upper part of a porcelain crucible is divided vertically into two halves by a thin porcelain plate; the crucible is closed by a porcelain cover, through which pass the carbon electrodes of a battery of 8-10 Bunsen-cells, one electrode on each side of the dividing vertical plate; indentations are cut in the negative electrode; the crucible is heated to redness, then filled with fused $MgCl_2$, and the current is passed through the molten mass. The Mg lodges in the cavities of the negative electrode, and is thus prevented from floating to the surface;

the dividing plate serves to prevent contact between the Cl evolved at the positive electrode, and the Mg (Bunsen, *A.* 82, 187).—2. A mixture of $MgCl_2$ and KCl, prepared by evaporating a mixture of the salts, in the ratio 4 $MgCl_2$:3 KCl, to dryness, is mixed with a little NH_4Cl , and is electrolysed when fused in the apparatus described in 1; as Mg is heavier than the molten mixture of salts it is not necessary to form serrations in the negative electrode (Matthiessen, *C. J.* 8, 107).—3. A mixture of 6 pts. dry $MgCl_2$, 1 pt. of a mixture of 7 pts. NaCl and 9 pts. KCl, 1 pt. powdered CaF_2 , and 1 pt. Na carefully freed from oil, is heated to bright redness in a covered earthen crucible. The Mg, which separates in globules, is heated nearly to whiteness in a boat of compact charcoal, placed in an inclined tube of the same material through which is passed a stream of dry H; the Mg condenses on the upper part of the tube; it is then melted into large globules with a flux of $MgCl_2$, NaCl, and CaF_2 . To free the Mg from C, Si, and N, it may be distilled in a current of H at a high temperature (Deville a. Caron, *A.* 63, 137; for an apparatus in which the distillation may be conveniently conducted v. Sonstadt, *J. pr.* 90, 307). In a later trial D. a. C. used 7 pts. $MgCl_2$, 4.8 pts. CaF_2 , and 2.3 pts. Na (*C. C.* 1863, 993).—4. Wöhler (*A.* 101, 362) reduces a fused mixture of $MgCl_2$, NaCl with excess of NaCl by Na; the mixture is obtained by adding excess of NaCl to $MgCl_2$ aq. and evaporating to dryness. The amount of $MgCl_2$ in the mixture must be known in order that the quantity of Na to be used may be calculated; for every 1 pt. $MgCl_2$ about $\frac{1}{2}$ pt. Na should be used.

Properties.—A silver-white, very lustrous, moderately hard, metal; malleable; not very tenacious; may be filed and polished; S.G. c. 1.75. Mg occludes c. $\frac{2}{3}$ its volume of H; by heating in *vacuo* the H is suddenly evolved. Obtained in lustrous, white, crystals; hexagonal, $a:c = 1:1.639$, isomorphous with Zn (Des Cloizeaux, *C. R.* 90, 1101). Unchanged in dry air; superficially oxidised in ordinary air. Heated in air, burns to MgO giving out a brilliant white light, very rich in actinic rays. Burns when heated in steam, also in CO_2 , and in SO_2 . Combines directly with the halogens, S, P, As, N. Hot water is slowly decomposed by Mg. Dissolves readily in dilute acids.

Mg is a distinctly metallic element; it forms one series of salts MgX_2 , where $X = Cl, NO_3, SO_4, PO_4$, &c.; a few basic salts, and many double salts, are known. In its chemical relations, Mg is analogous to the alkaline earth metals Ca, Sr, and Ba, and also to the metals Be, Zn, Cd, and Fe. MgO and $MgO_2 \cdot H_2$ are alkaline; $MgO_2 \cdot H_2$ is formed by the reaction of H_2O and MgO; and is dehydrated to MgO by heat. As the V.D. of no binary compound of Mg with H or one of the halogens has been determined, the valency of the atom of Mg in gaseous molecules is not known with certainty; but from the close similarities between Mg, Zn, and Cd, there is little doubt that the atom of Mg is divalent in gaseous molecules (v. MAGNESIUM GROUP OF ELEMENTS, p. 163; cf. ALKALINE EARTHS, METALS OF THE, vol. i. p. 112).

The atomic weight of Mg has been determined (1) by determining SO_4 in $MgSO_4 \cdot 7H_2O$

(Gay-Lussac, *A. Ch.* [2] 13, 808; Scheerer, *P.* 69, 535); (2) by converting MgO into $MgSO_4$ (Berzelius, *P.* 8, 188; Svanberg & Nordenfeldt, *J. pr.* 45, 474; Jacquellin, *A. Ch.* [3] 32, 202; Marignac, *A. Ch.* [6] 1, 289); (3) by converting $MgCO_3 \cdot 2H_2O$ into MgO (S. a. N. l.c.); (4) by converting $MgCO_3$ into MgO (Marchand & Scheerer, *J. pr.* 50, 885); (5) by determining Cl in $MgCl_2$ by ppn. with Ag (Dumas, *A. Ch.* [3] 55, 189); (6) by determining S.H. of Mg .

Molecular weight of magnesium.—Ramsay (*C. J.* 55, 521) has determined the lowering of vapour-pressure of Hg produced by dissolving Mg in Hg ; the results make it probable that the molecular weight of Mg is the same as the atomic weight. This conclusion assumes the accuracy of Van't Hoff's law, that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also supposes the molecular weight of liquid Hg to be the same as the atomic weight of Hg .

Reactions.—1. Slowly oxidised in moist air.—2. Decomposes warm water slowly; heated in steam burns to MgO .—3. Heated in air or oxygen to above its M.P. burns to MgO , with brilliant white light, rich in actinic rays.—4. Heated in chlorine, bromine, or iodine forms $MgCl_2$, $MgBr_2$, or MgI_2 .—5. Heated in sulphur forms MgS .—6. Heated in nitrogen forms Mg_3N_2 , with phosphorus forms Mg_3P_2 , and with arsenic forms Mg_3As_2 .—7. Decomposes carbon monoxide and dioxide, also sulphur dioxide, when heated in these gases, forming MgO .—8. Reduces ferric chloride and sulphate solutions to $FeCl_2$ and $FeSO_4$ (Pfeiffer, *J. pr.* 61, 441).—9. Reduces nitric acid to HNO_2 (Jenzsch, *N. T. für Mineralogie*, 1853, 635).—10. Reduces carbonates of the alkali metals except Ca , also oxides of copper, silver, and gold, when heated with them in solid form (Winkler, *B.* 23, 44); also reduces oxides of Ca , Sr , Ba , Zn , Cd , and Hg (W. B. 23, 120).—11. Dissolves in dilute acids with formation of salts MgX_2 , $X = Cl, SO_4$, &c., and evolution of H_2 , or N oxides from HNO_3 . Conc. hot H_2SO_4 forms $MgSO_4$ and SO_2 .—12. Dissolves in hydrogen peroxide solution with formation of MgO_2H_2 . From solutions of salts of copper, iron, manganese, and cobalt Mg ppt. the metals, with evolution of H_2 ; from some metallic salts Mg ppt. hydrated oxides, e.g. AlO_2H_2 , from solutions of Al salts; from solutions of salts of arsenic or antimony, Mg evolves AsH_3 or SbH_3 .—13. Mg forms alloys with most of the metals (*v. Magnesium, alloys of*).

• *Detection and estimation.*—Solutions of Mg salts are not pptd. by $HClAq$, H_2SO_4Aq , H_2S , or NH_4HS . Fixed alkalis and their carbonates ppt. MgO_2H_2 or $MgCO_3$, insoluble in excess, but soluble in NH_4 salts, especially in NH_4ClAq ; hence Mg salts are not pptd. by NH_4Aq in presence of NH_4Cl . Na_2HPO_4Aq , added to Mg salt solutions, in presence of NH_4Aq , ppt. $MgNH_4PO_4$.

Mg is usually estimated by ppn. as $MgNH_4PO_4$, by addition of NH_4Aq and Na_2HPO_4Aq ; when strongly heated, the pp. is changed to $Mg_3P_2O_7$. For details, and methods of separation of Mg from other metals, *Manuals of Analysis* must be consulted.

Magnesium, alloys of. Mg forms alloys with most of the metals. By reason of the easy

oxidation of Mg , the preparation of alloys of this metal is somewhat difficult. They may be prepared by melting the metals in H ; also by melting the other metal and rapidly immersing the Mg in it. According to Parkinson (*J. pr.* 101, 875), Mg forms alloys with the alkali metals, Al , Sh , Bi , Cd , Cu , As , Pb , Hg , Pt , Ag , Tl , Sn , Zn ; also with Cu and Ni together, but not with Co , Fe , or Ni alone. The alloys of Mg are generally very brittle.

Magnesium, aluminate of; $MgAl_2O_4$; *v. ALUMINATES*, vol. i. p. 141.

Magnesium, antimonate of; $Mg(SbO_3)_2 \cdot 12H_2O$; *v. ANTIMONATES*, vol. i. pp. 285, 286.

Magnesium, arsenates of; *v. ARSENATES*, vol. i. p. 808.

Magnesium, arsenide of. Mg_3As_2 . Brown mass. Formed by heating a mixture of As and Mg turnings in H (Parkinson, *J. pr.* 101, 875; cf. *ARSENIC, Combinations No. 9*, vol. i. p. 303).

Magnesium, arsenites of; *v. ARSENITES*, vol. i. p. 306.

Magnesium, borates of; *v. BORATES*, vol. i. p. 523, 530.

Magnesium, boride of. According to Phipson (*C. N.* 9, 219), a greenish-black mass, which is probably a boride of Mg , is produced by heating Mg with boric acid.

Magnesium, borofluoride of. $Mg(BF_4)_2$ (Berzelius, *P.* 2, 113), *v. BOROFLUORIDES*, vol. i. p. 526.

Magnesium, bromide of. $MgBr_2$. Mol. w. unknown, as V.D. has not been determined. Occurs in small quantity in sea-water, and in some mineral springs; also in the Stassfurt salt deposits. Obtained by passing HBr vapour over melted Mg . The reaction is very violent (Lerch, *J. pr.* [2] 23, 338). A white, very deliquescent, fusible, wax-like, crystalline mass. By concentrating a solution of MgO in $HBrAq$, white deliquescent crystals of the hydrated bromide, $MgBr_2 \cdot 6H_2O$, are obtained (Rammelsberg, *P.* 55, 235); the same hydrate is formed, along with an insoluble oxybromide, by the reaction between Mg and Br under water (Lerch, l.c.). Evaporation of $MgBr_2Aq$ to dryness, or heating the crystals of $MgBr_2 \cdot 6H_2O$, is attended with evolution of HBr and formation of an oxybromide. Heated in a stream of O , $MgBr_2$ is entirely decomposed to MgO (Schulze, *J. pr.* [2] 21, 407). Kremers (*P.* 108, 118) and Gerlach (*Fr.* 8, 285) give the following data for S.G., and percentage composition, of $MgBr_2Aq$:—

P.ct. $MgBr_2$	S.G. of solution	P.ct. $MgBr_2$	S.G. of solution
5	1.043	30	1.310
10	1.087	35	1.377
15	1.137	40	1.451
20	1.191	45	1.535
25	1.247	50	1.625

The double compounds $MgBr_2 \cdot KBr \cdot 6H_2O$ and $MgBr_2 \cdot NH_4Br \cdot 6H_2O$ are obtained by evaporating mixed solutions of the constituent salts (Lerch, *J. pr.* [2] 28, 338).

Magnesium, chloride of. $MgCl_2$. Mol. w. unknown, as V.D. has not been determined.

Occurrence.—In sea-water and in several mineral springs, also in the salt deposits of Stassfurt.

Formation.—1. The mother-liquor, after re-

moving KCl from the Stassfurt salts, is evaporated to S.G. 1.375 and allowed to crystallise. The crystals of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ are heated to melting, whereby they are partially dehydrated, but at the same time some oxychloride is formed. By exposing the crystals to a temperature of c. 100° under greatly reduced pressure almost pure MgCl_2 is obtained.—2. MgCl_2 is obtained as a by-product in Weldon's process for making Cl_2 , and in Solway's soda-ammonia process when MgO is used to decompose NH_4Cl .—3. By heating MgO with NH_4Cl , adding some NH_3 from time to time.

Preparation.—1. Powdered MgO , or *magnesia alba*, is dissolved in HClAq , NH_3Cl is added in quantity sufficient to prevent p.pn. of $\text{MgO} \cdot \text{H}_2\text{O}$ on addition of NH_4Aq , the solution is made slightly alkaline by NH_4Aq , any silica which separates is filtered off, the liquid is neutralised by HClAq , and evaporated to dryness. The double salt $\text{NH}_4\text{Cl} \cdot \text{MgCl}_2 \cdot 2\text{H}_2\text{O}$ is thus obtained; it is heated to melting (c. 460°) in a Hessian crucible, in the bottom of which is placed a smaller Pt dish (Bunsen, A. 82, 137), until NH_4Cl is entirely removed; the MgCl_2 collects in the Pt dish at the bottom of the Hessian crucible (cf. Döbereiner, S. 28, 90).—2. By heating $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ in a current of HCl (Hempel, B. 21, 897).

The hydrated chloride $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ is obtained by evaporating the solution of MgO in HClAq to the crystallising point.

Properties.—A white, deliquescent, solid, consisting of a mass of small pearly crystals; S.G. 2.177 (Playfair & Joule, C. S. Mem. 2, 401). Can be distilled in H at red heat. Dissolves readily in water with production of much heat; $[\text{MgCl}_2\text{Aq}] = 35,920$ (Th. 3, 243). Thomsen (l.c.) gives the thermal data $[\text{MgCl}_2] = 151,010$; $[\text{MgCl}_2\text{Aq}] = 186,930$. Sol. in alcohol, also in amyl alcohol. Gerlach (J. 1859, 43) gives the following table:—

P.ct. MgCl_2	S.G. MgCl_2Aq	P.ct. MgCl_2	S.G. MgCl_2Aq
1	1.0084	19	1.1686
2	1.0169	20	1.1780
3	1.0253	21	1.1879

The hydrate $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ crystallises in monoclinic forms; S.G. 1.558 (Fihol, A. Ch. [3] 21, 415). S. 187 cold water, 367 hot water (Casas, C. R. 87, 350). S. 20 in alcohol .9 S.G., 50 in alcohol .817 S.G.

Reactions.—1. When the crystals of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ are heated in air, water is given off and at the same time partial decomposition occurs with evolution of HCl and formation of

oxychlorides.—2. MgCl_2 is partly decomposed by much water to MgO and HCl .

Combinations.—1. With *magnesia* to form oxychlorides (v. *Magnesium, oxychlorides of*, p. 162).—2. With *potassium chloride* to form $\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$; occurs native as *carallite*, crystallising in rhombic forms according to Marignac (C. R. 155, 650), in hexagonal forms according to Rammelsberg (*Hand. der Krystall. Chemie*, 204). The double salt is prepared by mixing solutions of the constituents in the proper ratio, evaporating, and crystallising.—3. With *ammonium chloride*, and *calcium chloride*, to form $\text{MgCl}_2 \cdot \text{NH}_4\text{Cl} \cdot 6\text{H}_2\text{O}$ (v. Pfaff, A. Hantz, A. 66, 250), and $\text{MgCl}_2 \cdot \text{CaCl}_2 \cdot 12\text{H}_2\text{O}$, respectively.—4. With *sodium chloride* to form $\text{MgCl}_2 \cdot \text{NaCl} \cdot \text{H}_2\text{O}$ (Poggiale, C. R. 20, 1180).—5. With *ferric chloride*, and *chromic chloride*, to form $2\text{MgCl}_2 \cdot \text{Fe}_2\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, and $2\text{MgCl}_2 \cdot \text{Cr}_2\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, respectively (Neumann, A. 244, 328).—6. With *phosphorus oxychloride* to form $\text{MgCl}_2 \cdot \text{POCl}_3$ ($9\text{MgCl}_2 \cdot 10\text{POCl}_3$ according to Cronander, B. 4, 753); a deliquescent solid, decomposed by hot water (Casasemann, A. 98, 223). 7. With *iodine trichloride* to form deliquescent, easily decomposed, crystals of $\text{MgCl}_2 \cdot 2\text{ICl}_3 \cdot 5\text{H}_2\text{O}$; obtained by dissolving $\text{Mg}(\text{IO}_3)_2$ in conc. HClAq , leading HCl into the liquid to saturation, and surrounding by a freezing mixture (Fihol, J. Ph. 25, 442).—8. With *ammonia* to form $\text{MgCl}_2 \cdot 4\text{NH}_3$; a white sublimate by heating MgCl_2 in NH_3 (Clark, A. 78, 369).

Magnesium, chromate of; v. CHROMATES, vol. ii. p. 155.

Magnesium, fluoride of. MgF_2 . Mol. w. unknown as V.D. has not been determined. Occurs native as *sellaite*. Formed by dissolving *magnesia alba* in HFAq , evaporating to dryness, and heating the residue; also by ppg. a Mg salt in solution by a soluble fluoride. Obtained in crystals, either by melting the salt, prepared as described, with NaCl or KCl (Cossa, Z. K. [2] 1, 207), or by melting together 5 parts MgCl_2 , 4 parts NaF , and 4 parts NaCl (Röder). Four-sided, very hard, white needles. S.G. 2.856 at 12° (Cossa, B. 10, 295). Gunz (A. Ch. [6] 3, 5) gives the thermal data: $[\text{MgO} \cdot \text{H}_2, 2\text{HF}] = 28,400$. Forms a *double compound* with NaF , viz. $\text{MgF}_2 \cdot \text{NaF}$. Obtained by adding $\text{MgO} \cdot \text{H}_2$ to NaFAq and evaporating; the decomposition according to Tissier (J. pr. 90, 50) is

Magnesium, haloid compounds of. Mg forms a single compound, MgX_2 , with each of the halogens. None of these compounds has been g.a.fied, hence the molecular weight of none is known with certainty; but the great similarities between Mg , Zn , and Cd , make it extremely probable that the formula MgX_2 expresses the composition of the molecules of the compounds in question. MgCl_2 , MgBr_2 , and MgI_2 crystallise with $6\text{H}_2\text{O}$; when these crystals are heated they are partly decomposed to MgO and HX ($\text{X} = \text{Cl}$, Br , or I).

Magnesium, hydrosulphide of. $\text{MgS} \cdot \text{H}_2\text{S}$. A solution of this compound is obtained by passing H_2S through MgO suspended in water; the MgO dissolves and leaves a nearly colourless solution, which evolves H_2S when exposed to air or heated. The solution thus prepared contains c. 16 p.c. $\text{MgS} \cdot \text{H}_2\text{S}$ and has S.G. 1.118 at 12° .

MAGNESIUM, OXIDE OF.

(Divers & Shimidzu, *C. J.* 45, 699). $\text{MgS} \cdot \text{H}_2\text{O}$ is also formed by treating MgS with water. A solution of $\text{MgS} \cdot \text{H}_2\text{O}$ is a convenient source of H_2S ; a steady stream of the gas is obtained by heating to $60^\circ\text{--}85^\circ$ (*J. A. S. L.*). Thomsen gives the thermal data: [$\text{Mg}, \text{S}^\circ, \text{H}^\circ, \text{Aq}^\circ$] = 114,880 (*Th.* 3, 243).

Magnesium, hydroxide of. $\text{MgO} \cdot \text{H}_2\text{O}$. Occurs native as *brucite*, forming white, pearly, crystalline tablets (hexagonal rhombohedra), S.G. 2.35 to 2.46. Prepared by ppg. a Mg salt by NaOH aq, washing, and drying at 100° ; also by direct combination of water with MgO , and drying at 100° ; S.G. 2.36 at 15° (Schulten, *C. R.* 101, 72). MgO which has been heated to whiteness does not combine with water (v. Deville, *C. R.* 61, 975; Knapp, *D. P. J.* 202, 513; Schwarz, *D. P. J.* 186, 25; Ditte, *C. R.* 73, 111, 191, 270). [$\text{MgO} \cdot \text{H}^\circ$] = 217,320; [$\text{MgO} \cdot \text{H}^\circ \text{O}$] = 148,960 (*Th.* 3, 243). Soluble c. 100,000 parts water; $\text{MgO} \cdot \text{H}_2\text{O}$ aq is feebly alkaline to litmus; with acids $\text{MgO} \cdot \text{H}_2\text{O}$ reacts as a strong base, forming salts MgX_2 , $\text{X} = \text{Cl}, \text{NO}_3, \text{SO}_4, \text{PO}_4$, &c.; [$\text{MgO} \cdot \text{H}^\circ, \text{H}^\circ \text{SO}^\circ \text{Aq}^\circ$] = 31,220; [$\text{MgO} \cdot \text{H}^\circ, 2\text{HNO}^\circ \text{Aq}^\circ$] = 27,520; [$\text{MgO} \cdot \text{H}^\circ, 2\text{HClAq}^\circ$] = 27,690 (*Th.* 3, 243) (*cf.* *Magnesium, oxide of*).

Magnesium, iodide of. MgI_2 . Mol. w. unknown as V.D. has not been determined. Obtained by throwing I_2 in small quantities at a time, on to molten Mg (Lerch, *J. pr.* [2] 28, 338); reaction is very violent. A white, waxy solid; very deliquescent. A hydrate, $\text{MgI}_2 \cdot 8\text{H}_2\text{O}$ according to Lerch (*l.c.*), is formed by the reaction between I_2 and Hg under water (L), or by dissolving *magnesia alba* in HIAq and evaporating over H_2SO_4 ; very deliquescent. MgI_2 is decomposed by heating in air, giving off I_2 , and forming MgO ; heated in O it is entirely changed to MgO (Schulze, *J. pr.* [2] 21, 407). MgI_2 forms double compounds with KI and NH_4I (Lerch, *l.c.*). The following table is given by Kromers (*P.* 108, 118);—

P.c. MgI_2	S.G. $\text{MgI}_2 \cdot \text{Aq}$ at 19°	P.c. MgI_2	S.G. $\text{MgI}_2 \cdot \text{Aq}$ at 19°
5	1.043	35	1.395
10	1.088	40	1.474
15	1.139	45	1.568
20	1.194	50	1.668
25	1.254	55	1.780
30	1.320	60	1.915

Magnesium, nitride of. Mg_3N_2 . Mol. w. unknown, as V.D. has not been determined. Obtained in small transparent crystals by Deville & Caron in making Mg . Bregliab & Geuther (*A.* 123, 236) prepared Mg_3N_2 by heating Mg turnings in a stream of dry pure N . Mg_3N_2 is also formed, according to Mallet (*C. N.* 38, 89), when Mg is heated in a small quantity of air. Prepared by heating Mg in N , Mg_3N_2 is an amorphous, greenish-yellow, powder; becomes brown on heating. Heated in air it is slowly oxidised to MgO ; the oxidation is rapid when O is substituted for air. With water, forms MgO and NH_3 . With dilute acids, forms Mg salts and NH_3 salts. Heated in HCl , MgCl_2 and NH_4Cl are formed. Heated in dry H_2S , MgS and $(\text{NH}_4)_2\text{S}$ are slowly formed. Heated to redness in CO or CO_2 , MgO , C , and C_2N_2 are produced. POCl_3 vapour reacts to form MgCl_2 and P nitride.

Vol. III.

Magnesium, oxide of. MgO . (*Magnesia*.) Mol. w. unknown, as compound has not been gasified. S.G. 3.642 at 12° (Cossa, *B.* 10, 1747); S.G. crystallised 8.636 (Ebelmen, *J.* 4, 15); for S.G. of MgO heated to temperature from 350° to bright redness v. Ditte, *C. R.* 73, 111, 191, 270.

A new medicine was introduced in Rome in the beginning of the eighteenth century; the name *magnesia alba* given to it is supposed to have been suggested as a distinction from *magnesia nigra*, a term then applied to *pyrolustia*, MnO_2 . The preparation of the new medicine was kept secret. In 1709 Slevogt showed that *magnesia alba* could be obtained by ppg. the mother-liquor from the preparation of saltpetre by K_2CO_3 . *Magnesia alba* was supposed to be the same as lime, but Hoffmann found that some of its reactions differed from those of this compound. In 1755 Black demonstrated *magnesia alba* to be a compound of CO , with a new earthy base, to which he gave the name *magnesia*.

Occurrence.— MgO occurs as *periclase*; crystallised in regular octahedra; S.G. 3.67; usually coloured green from presence of a little FeO .

Formation.—1. By adding NaOH aq or KOH aq to solution of a Mg salt, washing, and strongly heating the pp. of $\text{MgO} \cdot \text{H}_2\text{O}$.—2. By calcining *magnesia alba*, a basic Mg carbonate obtained by ppg. a Mg salt by an alkaline carbonate (v. CARBONATES, vol. i. p. 699).—3. By burning Mg in O .—4. By decomposing $\text{MgCl}_2 \cdot \text{Aq}$ by calcined dolomite; $\text{MgCl}_2 \cdot \text{Aq} + \text{CaO} \cdot \text{MgO} = 2\text{MgO} + \text{CaCl}_2 \cdot \text{Aq}$.—5. In crystals same as *periclase*, by strongly heating powdered MgO in a slow stream of HCl gas (Deville, *A.* 120, 183); also by heating powdered MgO in a porcelain oven (H. Rose).

Preparation.—1. A boiling solution of pure $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ is ppg. by $\text{Na}_2\text{CO}_3 \cdot \text{Aq}$; after boiling for a little the pp. is washed and dried, and the product ($4\text{MgCO}_3 \cdot \text{MgO} \cdot 11\text{H}_2\text{O}$) is calcined in a Pt vessel until every trace of CO_2 and H_2O is removed.—2. *Magnesia alba* is treated with enough dilute HNO_3 aq to dissolve nearly but not quite all; after standing for some time in the air with frequent stirring, to ppt. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$, the liquid is filtered; the filtrate is mixed with a little pure MgSO_4 , alcohol is added, and, after digesting for some time with pure CaSO_4 , the liquid is evaporated to crystallisation, and again filtered; finally the filtrate is evaporated to dryness, the $\text{Mg}(\text{NO}_3)_2$ thus obtained is calcined, the residue is very thoroughly washed, and again calcined (Wurtz). (For preparation of pure MgO from *magnesite* v. Caron, *C. R.* 66, 840.)

Properties.—A white powder, more or less flocculent according to the temperature and length of time it has been heated. MgO absorbs water and CO_2 from the air, slowly forming $\text{MgCO}_3 \cdot x\text{MgO} \cdot \text{H}_2\text{O}$. It is slightly soluble in water; 1 part requires 55,368 cold or hot water for solution according to Fresenius, 100,000 to 200,000 according to Bineau. The solution of MgO is feebly alkaline to litmus. When very strongly heated MgO does not melt but gives out a very clear white light. Made into a paste with a little water, MgO sets to a hard, white mass (Deville, *C. R.* 61, 975); MgO which has been heated to whiteness does not set with water (v. Knapp, *D. P. J.* 202, 513; Schwarz, *D. P. J.* 186, 25). MgO reacts with acids as a strong base

forming salts MgX_2 , $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{3}PO_4$, &c.

Reactions.—1. With water to form the hydroxide $MgO.H_2O$.—2. Heated with ammonium chloride NH_4Cl , is evolved and $MgCl_2$ formed.—3. With acids MgO reacts as a strong base forming salts MgX_2 , $X = Cl, \frac{1}{2}SO_4$, &c.—4. With salts of heavy metals MgO reacts similarly to CaO, BaO , and SrO , ppg. hydrated oxides.—5. With carbon dioxide and water, basic carbonates $MgCO_3.xMgO.H_2O$ are formed.—6. Suspend in water through which is passed a current of hydrogen sulphide, a solution of $MgS_2.H_2$ is obtained (v. *Magnesium, hydrosulphide of*, p. 160).—7. Heated in carbon disulphide vapour, $MgO.MgS$ is formed (Reichel, *J. pr.* [2] 12, 55).

Magnesium, oxychlorides of. When freshly heated MgO is moistened with $MgCl_2$ aq., S.G. 1.16 to 1.26, the whole sets to a firm, hard mass, which probably consists of a mixture of oxychlorides $xMgO.yMgCl_2$ (v. Sorel, *C. R.* 65, 102). By warming 30 parts MgO with 1500 parts $MgCl_2$ in solution, in an atmosphere free from CO_2 , needle-shaped crystals slowly form; when washed free from $MgCl_2$, pressed, and dried over soda-lime, the crystals are $10MgO.MgCl_2.18H_2O$; dried at 110° they lose $4H_2O$ (Krause, *A.* 165, 38).

Magnesium, oxysulphide of. Mg_2OS ($=MgO.MgS$). An amorphous, reddish, solid; obtained, along with COS , by passing CS_2 vapour over heated MgO (Reichel, *J. pr.* [2] 12, 55).

Magnesium, phosphide of. Mg_3P_2 . A hard, brittle, steel-grey solid; obtained by heating molten P with Mg in H (Parkinson, *C. J.* [2] 5, 127, 309), or in a sealed glass tube (Emmerling, *B.* 12, 152). Decomposed by water, evolving PH_3 , and forming MgO ; with acids gives Mg salts and PH_3 .

Magnesium, salts of. Compounds obtained by replacing H of acids by Mg. The salts of Mg belong to one series, MgX_2 , where $X = Cl, NO_3, \frac{1}{2}SO_4, \frac{1}{3}CO_3, \frac{1}{3}PO_4$, &c. A few basic salts, and many double salts, of Mg are known. $MgCO_3$, the basic carbonates and phosphates, and a few other salts are insoluble in water, but most of the Mg salts readily dissolve in water. The salts are usually prepared by dissolving $MgO, MgO.H_2O$, or $MgCO_3$, in the various acids, and evaporating, some are prepared by double decomposition from the soluble salts, generally from $MgSO_4$. As none of the salts of Mg has been gasified the formulæ given are not necessarily molecular, they are based on the results of analysis and considerations of the similarities between the salts of Mg, Zn, and Cd (v. *MAGNESIUM GROUP OR ELEMENTS*). The Mg salts are numerous, and as a class very definite and stable bodies; the following are the chief salts derived from oxyacids:—bromate, carbonates, chlorate, dithionate, hypochlorite, hypophosphite, iodate, nitrate, and -ite, perchlorate, iodates, phosphates and -ite, selenate and -ite, silicates, sulphate and -ite, tellurate and -ite, thiosulphate (v. *CARBONATES, NITRATES, SULPHATES*, &c.).

Magnesium, selenide of. A flesh-coloured pp., probably a selenide of Mg, is obtained by adding K_2Se to solution of a Mg salt; the pp. is decomposed by heat, and by acids, with separation of Se (Berzelius).

Magnesium, silicides of. A compound of Mg and Si is prepared by placing a layer of fused and powdered NaCl in the bottom of a Hessian crucible, adding one-half of a mixture of 2½ parts NaCl and 7 parts Na_2SiF_6 , then 2½ parts Mg, and then the other half of the mixture of NaCl and Na_2SiF_6 , covering the whole with NaCl, and heating in a wind-furnace; when the reaction is completed the contents of the crucible are stirred with a porcelain rod, and allowed to cool. The regulus formed at the bottom of the crucible is a mixture of Mg and Mg silicide; by washing with NH_4Cl aq. the Mg is dissolved out (Geuther, *J. pr.* 95, 424). As thus prepared the silicide has the composition Mg_2Si . It forms metal-like, lustrous crystals. Reacts with HCl aq. to form $MgCl_2, SiH_4, H_2SiO_3$, and H. This substance may be a compound, or a mixture, of Mg_2Si and $MgSi$ ($Mg_2Si = 2Mg.Si + MgSi$). A silicide Mg_2Si is obtained by pulverising, in a warm mortar, 40 parts fused $MgCl_2$, 35 parts Na_2SiF_6 , 10 parts NaCl, adding 20 parts Na in small pieces, and projecting the mixture into a hot Hessian crucible. After fusion, and cooling, the greyish-black mass in the crucible is found to contain metal-like tablets and globules; these consist of Si and Mg_2Si ; by treating with HCl aq. Si remains and SiH_4 is evolved (Wöhler, *A.* 107, 113; cf. Martius, *A.* 107, 119).

Magnesium, silicofluoride of. $MgSiF_6$; said to be obtained as a gum-like, very soluble substance, by dissolving MgO in H_2SiF_6 aq. (Berzelius).

Magnesium, sulphhydrate of, v. Magnesium, hydrosulphide of, p. 160.

Magnesium, sulphides of. MgS has been isolated; polysulphides, probably MgS_2, MgS_3 , and MgS_4 , seem to exist in the solution obtained by warming MgS with S and H_2O .

MAGNESIUM MONOSULPHIDE, MgS . Produced by passing H laden with S vapour over red-hot Mg (Reichel, *J. pr.* [2] 12, 55; cf. Parkinson, *C. J.* [2] 5, 125, 309). According to Fremy, MgS is formed, along with COS , when MgO is strongly heated in dry H_2S ; but Reichel (l.c.) says that the products of this reaction are $MgO.MgS$ and COS . MgS is also said to be formed, along with $(NH_4)_2S$, by heating Mg_3N_2 in dry H_2S (Briegleb & Geuther, *A.* 123, 236). Fremy (*J. Ch.* [5] 38, 324) gives $[Mg.S] = 39,800$. MgS is formed, but only in very small quantity, by strongly heating $MgSO$, with C. Alkaline sulphides do not ppt. MgS , but $MgO.H_2O$, from solutions of Mg salts.

MgS , formed by heating Mg and S, is described as a yellowish-grey amorphous, or as a reddish-brown crystalline, mass; analysis always gives rather more S than required by MgS . With water, MgS is decomposed to $MgO.H_2O$ and $MgS.H_2Aq$, the latter being afterwards converted into $MgO.H_2O$ and H_2S .

MAGNESIUM POLYSULPHIDES. By warming, not boiling, MgS and S with water, a dark yellow solution is obtained, containing Mg and S in a ratio varying from $Mg:S$ to $Mg:S$ (Reichel, *J. pr.* [2] 12, 55). The solution decomposes in air, giving off H_2S and ppg. $MgO.H_2O$ and S.

Magnesium, sulphocyanide of; $Mg(SCN)_2.4H_2O$; v. vol. ii. p. 350.

M. M. P. M.
MAGNESIUM ETHIDE $Mg(C_2H_5)_2$. Magnesium filings act rapidly on ethyl iodide, gas

being given off. If the product be heated in a sealed tube at 125° the contents solidify to a white mass which on distillation gives off MgEt_2 and leaves a residue of MgI_2 (Cahours, *A.* 114, 227, 354; Hallwachs a. Schafarik, *A.* 109, 215). These statements are contradicted by Löhr (*A.* 161, 48), who finds that EtOAc must be added to the mixture of Mg and EtI , and that the resulting magnesium ethyl is a non-volatile solid.

MAGNESIUM GROUP OF ELEMENTS—

Beryllium, Magnesium, Zinc, Cadmium, Mercury. Of these five metals, only Zn and Hg are found native, and these in small quantities. Be occurs chiefly as silicate in combination with Al silicate, not widely distributed; Mg salts, especially MgCO_3 and MgSO_4 , are found in large quantities; the chief ores of Zn are ZnCO_3 and ZnS , they occur fairly widely distributed and in considerable quantities; small quantities of CdS and CdCO_3 accompany many Zn ores; the chief ore of Hg is HgS , which is found only in

a few localities. Be is classed with the rare elements; approximately pure Be was not prepared until 1895. Mg was obtained by Davy, in small quantity and impure, in 1800; in 1850 Bussy prepared the metal in a state of approximate purity. Although brass has been made for very many centuries, yet it was not till the middle of the eighteenth century that the art of preparing metallic Zn was known in Europe. Cd was discovered and prepared in 1817 by Stromeyer. Hg has been known certainly from the beginning of the Christian era.

Be and Mg are prepared by reducing the chlorides MgCl_2 by Na or K ; ZnO and CdO are reduced by heating with C ; Hg is prepared from HgS by heating with CaO , whereby CaS and CaSO_4 are formed and Hg is vapourised, or by heating with scrap iron, when FeS , SO_2 , and Hg are produced.

The following table presents some of the prominent physical and chemical properties of the magnesium metals:—

	BERYLLIUM	MAGNESIUM	ZINC	CADMIUM	MERCURY
Atomic weights	90.8	24	64.9	111.7	199.8
	One or more compounds of each element, except Mg , have been gasified. Specific heats have been directly determined. Molecular weights of Zn , Cd , and Hg , and probably also of Mg , are the same as the atomic weights.				
Melting-points (approx.)	—	700°–800°	430°	320°	–39°
Sp. gr. (approx.)	1.85	1.7	7.2	8.7	13.5

At. w.	4.92	14.1	9	12.8	14.8
Sp. gr. (approx.)					
Occurrence and preparation	Double silicate of Be and Al , and a compound of BeO and Al_2O_3 , occur in a few rocks in small quantities. Prepared by reduction of molten BeCl_2 by Na ; not by electrolysis of BeCl_2 .	MgCO_3 , MgSO_4 , MgCl_2 , and Mg silicates occur in large quantities and widely distributed. Prepared by reducing molten MgCl_2 by Na ; also by electrolysis of MgCl_2 .	ZnO , ZnS , and ZnCO_3 are fairly widely distributed; Zn found native in small quantities. Prepared by reducing ZnO by C at moderately high temperature.	Compounds frequently found accompanying Zn ores. Prepared by reducing CdO by C .	Hg found native in small quantities. Chief ore is HgS ; found in a few localities in fair quantity. Prepared by heating HgS in air, or with Fe , or CaO , and condensing Hg .
Physical properties	Steel-coloured, hard, hexagonal crystals; lustrous.	Silver-white, very lustrous; moderately hard; malleable; not very tenacious. Crystallises in hexagonal forms, isomorphous with Zn . Melts at temp. much higher than M.P. of Cd or Zn ; has not been gasified at white heat.	White, with tinge of blue; crystallises in hexagonal forms; soft; brittle at ordinary temperatures, inalterable at 100°–150°, brittle again at 200°. Flexibility varies with temp. Melts at c. 430°; can readily be distilled.	White, with slight tinge of blue; crystallises easily in regular forms; soft, but harder than Zn ; very malleable, ductile, and flexible. Vapour is yellow. Melts at moderate temperature, c. 320°; distils at lower temp. than Zn .	Liquid metal at temps. above –39°; white, showing faint tinge of blue when compared with Ag ; very lustrous. Crystallises in regular octahedra. Boils at c. 350°. Volatilises even at very low temperatures.

TABLE—cont.

C.	BERYLLIUM	MAGNESIUM	ZINC	CADMIUM	MERCURY
<i>Chemical properties</i>	Scarcely changed by heating in air or O; burns in O-H flame to BeO. Scarcely acted on by S at red heat. Burns in Cl to BeCl ₂ . Dissolves slowly in acids to form salts. Only one series of salts known, BeX ₂ , where X = Cl, $\frac{1}{2}$ SO ₄ , $\frac{1}{2}$ PO ₄ , &c. Dissolves slowly in alkali solutions, evolving H. Distinctly positive metal; does not show allotropic; BeO has no acidic properties. Atom of Be is divalent in gaseous molecules.	Unchanged in dry air; heated in air, or O, burns to MgO. Decomposes hot water slowly; burns when heated in steam, forming MgO. Decomposes CO ₂ at red heat. Combines directly with halogens S, F, As, and N. Dissolves in acids to form salts. Only one series of salts is known, MgX ₂ , X = Cl, $\frac{1}{2}$ SO ₄ , &c. MgO.H ₂ is a strong base; compounds of Mg do not show any acidic properties. Valency of atom of Mg not certainly known, as no binary haloid compounds have been gasified. Mol. w. probably same as at. w.	Unchanged in air; heated strongly in air, or O, burns to ZnO. Decomposes steam at red heat. Combines directly with halogens, but not with S. Slowly soluble in alkali solution, with evolution of H. Dissolves in acids to form salts. One series of salts known, ZnX ₂ , X = Cl, &c. ZnO.H ₂ dissolves in alkalis, but is ppd. again on evaporation over H ₂ SO ₄ <i>in vacuo</i> . There are indications of existence of a hydride of Zn. Atom of Zn is divalent in gaseous molecules. Mol. w. same as at. w.	Slowly oxidised on surface in air; heated in air or O, burns to CdO. Cd vapour and steam heated together form H and CdO. Combines directly with halogens, also with S and P. Dissolves in acids to form salts. Only one series of salts known, CdX ₂ , X = Cl, &c. CdO.H ₂ is not soluble in alkalis. No compound of Cd shows any acidic properties. Atom of Cd is divalent in gaseous molecules. Mol. w. same as at. w.	Unchanged in air; heated nearly to B.P. is slowly oxidised to HgO. Does not decompose water or steam. Combines directly with halogens and S. Dissolves in acids to form salts. Two series of salts are known, HgX and HgX ₂ , X = Cl, &c.; salts of both series are numerous and stable. HgO dissolves in molten KOH to form K ₂ O.2HgO; HgS dissolves in Na or K sulphide solution to form compounds α Na ₂ S.yHgS. Hg forms very many ammonio-compounds. Atom of Hg is mono- and di-valent in gaseous molecules. Mol. w. same as at. w.

General formulae and character of compounds.

Oxides:—MO; also in case of Hg, Hg₂O.
Hydroxides:—MO.H₂. Sulphides:—MS; also in case of Hg, Hg₂S. Haloid compounds:—MX₂; also in case of Hg, HgX. Salts:—MX₂; also in case of Hg, MX; X = NO₃, ClO₄, $\frac{1}{2}$ CO₃, $\frac{1}{2}$ SO₄, $\frac{1}{2}$ PO₄, &c.

The oxides MO are basic; they react with acids to form salts MX₂, X = NO₃, $\frac{1}{2}$ SO₄, &c. MgO reacts with water to form MgO.H₂; the other hydroxides MO.H₂ are formed by ppd. solutions of salts by alkalis. HgO shows feebly marked acidic properties; it dissolves in molten KOH, and the compound 2HgO.K₂O is obtained on cooling. ZnO.H₂ is sol. KOHAq, but is reppd. on evaporation *in vacuo* over H₂SO₄. Mercurous oxide Hg₂O is the only representative of the class MO; it is very easily resolved into Hg and HgO; it reacts with dilute acids, in the cold, as a basic oxide, forming salts HgX. Hg₂O in some respects resembles Cu₂O and Ag₂O, and exhibits the relations of Hg to the copper group (v. COPPER GROUP OF ELEMENTS, vol. ii. p. 250).

The hydroxides MO.H₂ are all decomposed

by heat to MO and H₂O; HgO.H₂, if it exists is extremely easily separated into its oxide and H₂O; the only hydroxide obtained by direct reaction between MO and H₂O is MgO.H₂. The hydroxides are basic; MgO.H₂ is slightly alkaline.

The sulphides MS are basic. The existence of BeS is extremely doubtful; MgS is readily decomposed by water, giving MgS.H₂Aq, and finally K₂O.H₂ and H₂S; ZnS, CdS, and HgS are more stable than MgS; HgS shows slightly acidic properties, it dissolves in K₂SAq or Na₂SAq to form compounds α K₂S.yHgS. Mercurous sulphide Hg₂S is very easily decomposed to HgS and Hg.

The haloid compounds MX₂ may be obtained by the direct union of the elements; the mercurous compounds HgX are also obtained in this way. MX₂ and HgX are also prepared by dissolving the corresponding oxides in HXAq and evaporating; but MgCl₂ cannot be thus obtained, as evaporation towards dryness of MgCl₂Aq results in formation of HCl and MgO mixed with oxychlorides α MgO.yMgCl₂. The compounds

BeCl_2 , BaBr_2 , ZnCl_2 , CdBr_2 , HgCl_2 , HgI_2 , and probably HgCl , have been vapourised without decomposition. The bivalent compounds form many double compounds. They all combine with NH_3 ; various ammonio-derivatives of HgX_2 and HgX are known. Numerous oxyhaloid compounds, xMO.yMX_2 , are known.

The salts MX_2 are numerous and well marked; they are obtained by dissolving the corresponding oxides or carbonates in acids, and evaporating. Mercurous salts HgX are prepared by digesting excess of Hg with the various acids in the cold. Many basic salts of Be , Zn , and Hg have been prepared; most of the salts of Mg are normal.

The five metals Be , Mg , Zn , Cd and Hg belong to Group II., as the elements are arranged in accordance with the periodic law. The following table shows their positions in the Group:—

Even Series.				
2	4	6	8	
Be = 9	Ca = 40	Sr = 87	Ba = 137	
Odd Series.				
3	5	7	9	11
Mg = 24	Zn = 65	Cd = 112	—	Hg = 200

The properties of Be , the first member of the group, suggest those both of the even and odd series members. Physically it approaches Mg , Zn , and Cd more than Ca , Sr , and Ba ; in the conditions under which it is oxidised, the basic but non-alkaline character of its hydroxide, the existence of many basic salts, &c., Be shows closer resemblances to Zn , Cd , and Hg than to Ca , Sr , and Ba . The solubility of BeO.H_2 in KOH also suggests the solubility of ZnO.H_2 in KOH , and of HgO in molten KOH ; the hydroxides of Ca , Sr , Ba , and Mg are quite insoluble in alkalis. Mg is closely related in many respects to the metals of the alkaline earths, Ca , Sr , and Ba ; but its much greater stability in air, its non-decomposition of cold water, the easy resolution of its hydroxide into MgO and H_2O by heat, &c., exhibit the analogies between Mg and Zn , Cd , Hg . Sulphides of Ca , Sr , and Ba are readily formed, but MgS is only produced by heating Mg to redness in H_2 laden with S vapour; the difficulty of forming MgS recalls the non-isolation of any compound of Be and S . Alkali carbonate solutions ppt. MCO_3 from solutions of salts of Ca , Sr , and Ba ; but the pps. obtained from Mg salts are basic carbonates $\text{xMgCO}_3.y\text{MgO.H}_2$. The sulphates of Ca , Sr , and Ba are reduced to MS by heating with C , but MgSO_4 is scarcely, if at all, reduced in this way. Hg is distinguished from the other members of the magnesium family by its physical properties, the formation of two series of salts, the formation of a large number of ammonio-derivatives of both series of Hg salts, and in other ways.

In the composition of their salts, and sometimes in the isomorphism of salts, the metals of the Mg family resemble those of the Fe family, viz. Mn , Fe , Ni , Co (v. IRON GROUP OF ELEMENTS, p. 65). For a further treatment of the elements of Group II. v. CLASSIFICATION, vol. ii. pp. 204-207; cf. also ALKALINE EARTHS, METALS OF THE, vol. i. p. 112.

M. M. P. M.

MAGNETIC ROTATORY POWERS of liquid compounds; v. PHYSICAL METHODS, section Optical methods.

MAIROGALLOL $\text{C}_{10}\text{H}_6\text{Cl}_2\text{O}_2$ (?) [190°]. From *maipo*, I glitter. Obtained, together with leucogallol, by passing chlorine through pyrogallol (15 g.) dissolved in 60 p.c. acetic acid (46 g.) until the liquid is brown, and allowing the liquid to stand (Groves, A. 179, 237; Stenhouse & Groves, C. J. 28, 706; Webster, C. J. 45, 208). Tri-metric prisms, insol. water, v. sol. hot alcohol, extremely sol. ether, insol. CS_2 and petroleum ether. Decomposed by boiling with water yielding CO , oxalic acid, and tri-chloro-pyrogallol. Reduced by zinc and H_2SO_4 to tri-chloro-pyrogallol (Webster, C. J. Proc. 3, 130; Hantzsch & Schniter, B. 20, 2033). Boiling with dilute H_2SO_4 gives a condensation product, and also a substance that is ppt. from aqueous solution by gelatin. Aqueous NaHSO_3 and zinc-dust reduce it to tri-chloro-pyrogallol and an amorphous substance which yields furfuraldehyde when distilled with dilute H_2SO_4 . Mairogallol gives a crimson colour with solution of sodium sulphite (Cross & Bevan, C. J. 43, 18). Mairogallol when gradually heated gives a sublimate of tri-chloro-quinone and tetra-chloro-quinone. These reactions indicate that mairogallol is derived by condensation from $\text{CO} < \begin{smallmatrix} \text{C(OH)} \\ \text{C(OH)} \end{smallmatrix} > \text{CCl}_2$ (Webster).

MALACHITE GREEN v. TETRA-METHYL-DIAMIDO-TRI-PHENYL-CARBINOL.

MALAMIC ACID v. MALLIC ACID.

MALEIC ACID $\text{C}_4\text{H}_2\text{O}_4$, i.e.

$\text{CO}_2\text{H.CH:CH.CO}_2\text{H}$. Mol. w. 116 (confirmed by Raoult's method, Paternò, B. 21, 2158). [130°]. R_D 38.6 (in a 6.9 p.c. aqueous solution; Kannonikoff, J. pr. [2] 31, 347; cf. Knop, A. 248, 175). H.C. v. 331,702 (Lougouine, C.R. 106, 1290). H.C. v. 326,900 (Stohmann, Kleber & Langbein, J. pr. [2] 40, 217). H.C. p. 326,300 (S. K. a. L.). H.F. 187,700 (S. K. a. L.). Heat of solution: -4,438 (Gal & Werner, B. [2] 47, 158). Heat of neutralisation: 26,648 (G. a. W.).

Formation.—1. Together with fumaric acid (q. v.) by the distillation of maleic acid (Lassaigne A. Ch. [2] 11, 93; Pelouze, A. Ch. [2] 56, 72; Liebig, A. 11, 276; Buchner, A. 49, 57; Kekulé A. Suppl. 1, 129; 2, 85; Von Richter, Z. [2] 5 453).—2. By heating silver succinate at 180° (Bourgoïn, C. R. 72, 52).—3. By saponification of the ether obtained from di-chloro-acetic ether by heating with reduced silver at 220°, or by the action of sodium upon its ethereal solution in the cold (Tanatar, B. 12, 1563).—4. By the action of KCN on α -di-bromo-propionic acid (Tanatar, B. 13, 159).—5. From (8)-bromo-pyromucic acid and dilute HNO_3 (Hill & Sanger, A. 232, 65).—6. By the action of baryta on tri-

chloro-phenomalic acid $\begin{pmatrix} \text{CH}_2\text{C(OH).CCl}_2 \\ \parallel \\ \text{CH.CO} \end{pmatrix}$.

Preparation.—Maleic acid is rapidly distilled until the residue thickens, the flame being the withdrawn; the distillation then continues by itself until the residue is solid (fumaric acid). The distillate consists of maleic acid and maleic anhydride, and may be wholly converted into maleic anhydride by AcCl . The maleic anhydride may be purified by crystallisation from

HOAc and then converted by hot water into maleic acid (Anschütz, *B.* 12, 2281; cf. Perkin, *B.* 14, 2547).

Properties.—Monoclinic prisms. V. sol. water and alcohol, m. sol. ether. Its aqueous solution reddens litmus strongly. Begins to boil at 160°, being then restored into maleic anhydride and water, which partially re-unite in the receiver. An aqueous solution of maleic acid is ppd. by baryta (difference from fumaric acid). Unlike fumaric acid, maleic acid is not ppd. by adding mineral acids to solutions of its salts.

Reactions.—1. Reduced by water and sodium amalgam to succinic acid. Zinc added to an aqueous solution of maleic acid yields zinc maleate and succinate.—2. Calcium maleate fermented in contact with cheese also changes to succinate (Dessaignes).—3. *Electrolysis* gives acetylene, succinic acid, and a small quantity of fumaric acid (Kekulé, *A.* 130, 1).—4. Combines readily with bromine in the cold, forming iso-di-bromo-succinic acid and some di-bromo-succinic acid derived from fumaric acid into which a portion of the maleic acid is at the same time transformed (Kekulé; Petri, *A.* 195, 59). Chlorine gives a di-chloro-succinic acid (Petrieff, *Bl.* [2] 41, 309). Bromine in presence of water forms iso-di-bromo-succinic, bromo-fumaric, bromo-succinic, and fumaric acids (Wislicenus, *A.* 246, 53).—5. Dissolves easily in aqueous HBr, the solution even at 0° soon depositing fumaric acid and bromo-succinic acid in equimolecular proportions. The bromo-succinic acid may easily be extracted from the product by water (Fittig a. Dorn, *B.* 9, 1191).—6. Converted into fumaric acid by boiling conc. HIAq, HIBaq, dilute HNO₃, or HClAq (Kekulé, *A. Suppl.* 1, 184; 2, 93; Kekulé a. Strecker, *A.* 223, 186). When HIAq is used the ultimate product is succinic acid. Dry HCl does not convert maleic acid into fumaric. Maleic acid is converted into fumaric acid by heating its aqueous solution at 100°–130° (Semenoff, *Bl.* [2] 46, 816). An aqueous solution of sodium maleate is not affected by being heated for 10 hours in sealed tubes at 100° to 135°.—7. With hypochlorous acid it forms a compound which reduced by sodium amalgam yields inactive malic acid, oxymaleic acid (?), and a liquid which breaks up on heating into CO₂ and C₂H₄O₃ (Petrieff).—8. KMnO₄ oxidises it to inactive tartaric acid.—9. Alcoholic NH₃ at 150° slowly forms aspartic acid (Engel, *C. R.* 104, 1805).—10. The acids of the maleic series readily split off H₂O from their acid aniline salts, when the aqueous solution of the latter is left to stand for several days or boiled; a crystalline pp. being formed of the acid anilide X" $\begin{smallmatrix} \text{CONHPh} \\ \text{CO}_2\text{H} \end{smallmatrix}$ or of

an isomeride thereof. Under the same conditions the acid aniline salts of the acids of the fumaric series are quite stable. This constitutes a ready method of determining to which of the two isomeric series a given acid belongs. The acid is half neutralised with aniline and either left to stand or heated to boiling, if a pp. is obtained insoluble in dilute HCl the acid belongs to the maleic series (Michael, *B.* 19, 1872).

Salts.—K₂A" (dried at 100°). Radiating crystals; v. sol. water, insol. alcohol.—KHA" & aq: small crystals; v. sol. water. The solution reddens litmus. Na₂A": needles. Ppd. as a

granular crystalline powder by adding alcohol to its aqueous solution. Is not deliquescent.—NaHA" & aq: Triclinic crystals (Bodewig, *J.* 1881, 716). Sl. sol. cold water.—KNaA" & aq: deliquescent crystalline powder (Büchner, *A.* 49, 60).—BaA" & aq: gelatinous pp., changing to scales. S. 11 at 20° (Regnault).—BaA" & aq (Anschütz).—BaH₂A", & aq: indistinct crystals, which reddens litmus; v. sol. water (Büchner).—CaA" & aq (dried at 100°): small needles, sol. water.—CaH₂A", & aq: long prisms, v. sol. water, insol. alcohol.—SrA" & aq: silky needles.—SrH₂A", & aq: rectangular prisms.—MgA" & aq.—MgH₂A", & aq: hard crystals, v. sol. water, insol. alcohol.—ZnA" & aq: crystals, v. sol. water, insol. alcohol.—NiA" & aq: apple-green crystals.—CuA": light-blue crystals, sl. sol. boiling water, v. sol. NH₄Aq, forming a solution whence alcohol ppds. an azure-blue crystalline powder.—PbA" & aq: amorphous pp., changing to needles.—PbA"O (dried at 100°; Otto, *A.* 127, 178).—AgA": white pp., changing to lustrous needles.—AgHA" (dried at 100°): needles.

Acid aniline salt C₆H₅NH₂HA" & aq: prisms, sol. water. On allowing the solution to stand for some days it forms phenyl-aspartic acid C₆H₅NH.C₂H₄(CO₂H)₂ [132°] (Anschütz a. Wirtz, *A.* 239, 140; cf. Michael, *B.* 19, 1873; *Am.* 9, 183, 197).—The neutral aniline maleate when boiled in aqueous solution deposits the phenylimide of phenyl-aspartic acid C₆H₅NH.C₂H₄$\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}$NC₆H₅, a body [212°] which was formerly described as the di-anilide of maleic acid C₂H₂(CONHPh)₂.

Phenyl-imide C₂H₂$\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}$NC₆H₅, [91°]. (162° at 12 mm.). Formed by the dry distillation of acid aniline maleate (Anschütz a. Wirtz, *Am.* 9, 238; cf. Michael a. Wing, *Am.* 7, 280). Long yellow needles; v. sol. benzene, CHCl₃, ether, and alcohol; sl. sol. CS₂ and ligroin. Its solution in chloroform takes up bromine, forming the phenyl-imide of di-bromo-succinic acid [159°]. Baryta-water at 40° gives the acid anilide of fumaric acid.

Mono-methyl ether HMeA". Probably exists in the solution of maleic anhydride in MeOH. Such a solution becomes hot when mixed with NaOMe, probably forming NaMeA", but the solution presently deposits a bulky white, partly crystalline, pp., which forms an alkaline aqueous solution, becoming neutral on boiling; the neutral solution contains the methyl derivative of sodium methyl maleate C₂H₃(OMe)(CO₂Na)(CO₂Me) (Purdie, *C.* 47, 873).

Di-methyl ether MeA". (205° i.v.). S.G. 1.153. H.C. 669,570 (Ossipoff, *C. R.* 109, 312). From silver maleate and MeI, excess of iodine being avoided, as this would convert it into di-methyl fumarate (Anschütz, *B.* 12, 2282). Bromine effects the same change.

Mono-ethyl ether HEtA". From the anhydride and boiling alcohol. Also from HAga" and EtI (Ossipoff, *J. R.* 20, 254). Not identical with the mono-ethyl ether of fumaric acid. Forms a salt NaEtA". By treating HEtA" with NaOEt and boiling the product with water C₂H₃(OEt)(CO₂Et)(CO₂Na) is obtained, identical with that derived from fumaric acid (Purdie).

Di-ethyl ether Et.A. (225° i. v.). From $\text{Ag}_2\text{A}'$ and EtI (Anschütz, *B.* 11, 1644; 12, 2281). Vapour density corresponds to the formula (Q). Colourless liquid. Converted by iodine into the fumaric ether. Bromine gives di-bromo-succinic ether. Boiling with NaOMe forms a product whence boiling water produces $\text{C}_2\text{H}_5(\text{OMe})(\text{CO}_2\text{Et})_2$ (Purdie, *C. J.* 47, 868).

Di-isopropyl ether $\text{Pr}_2\text{A}'$. Vapour density corresponds to the formula.

(Anschütz); [57°] (Pelouze, *A. Ch.* [2] 56, 72); [60°] (Fittig, *A.* 188, 87). (202° i. v.). (*A.*) V.D. 48 ($\text{H} = 1$) (calc. 49) (Hübner a. Schreiber, *Z.* [2] 7, 712). *H.C.* 336,920 (Ossipoff, *C. R.* 109, 311). Appears to be the sole anhydride of both fumaric and maleic acids.

Formation.—1. By rapidly distilling maleic or fumaric acid, and frequently rectifying the product (Pelouze, *A.* 11, 263; Kekulé, *A. Suppl.* 2, 87). *In vacuo*, maleic acid splits up into water and anhydride even at 100° (Reicher, *R. T. C.* 2, 312).—2. By heating fumaric acid with AcCl and HOAc at 100°.—3. From silver fumarate and fumaryl chloride (Perkin, *B.* 14, 2545).—4. By distilling chloro- or bromo-succinic anhydride (Anschütz a. Benfiet, *B.* 15, 643).—5. By distilling malic anhydride.

Preparation.—1. Malic acid is treated with an excess of acetyl chloride, and the product (which probably chiefly consists of acetyl-malic anhydride) is distilled, when it splits up into acetic acid and maleic anhydride; the yield is 45 p.c. (Perkin, *C. J.* 39, 562; *B.* 14, 2547).—2. By dry distillation of malic acid and treatment of the residue and distillate with AcCl ; the yield is 56 p.c. of the theoretical (Anschütz, *B.* 12, 2281).

Properties.—Trimetric crystals, $a:b:c = 6408:1:4807$ (Bodewig, *B.* 14, 2788). In contact with water it is converted into maleic acid, which is conveniently prepared in this way. The abnormal rapidity of the etherification of maleic acid by heating with alcohols appears to be due to an intermediate formation of anhydride (Reicher, *R. T. C.* 2, 308). Maleic anhydride heated in a sealed tube at 260° gives a carbonaceous residue and gases (Semenoff, *Bl.* [2] 46, 816).

Reactions.—1. Unites with bromine at 100°, forming iso-di-bromo-succinic anhydride, which is resolved at 180° into HBr and bromo-maleic anhydride.—2. PCl_5 gives the chloride of fumaric acid (Perkin, *B.* 14, 2548), but maleyl chloride (71° at 11 mm.) appears to be first formed (Anschütz a. Wirtz).—3. With a saturated solution of HCl in HOAc it forms at 100° chloro-succinic acid.—4. When heated with phenylhydrazine (1 mol.) at 150° it forms the phenylhydrazide $\text{C}_6\text{H}_5\text{C}_2\text{O}_2\text{N}_2\text{HPh}$, which crystallises in needles [259°], and turns brown at 180° (Hütte, *J. pr.* [2] 35, 295).—5. When heated with phenols it produces fluorescent compounds analogous to the phthaleins, which may therefore be called 'maleins.' The resorcin-malein has a green fluorescence, (a)-naphthol-malein has a greenish-red fluorescence (Burckhardt, *B.* 18, 2864).

Constitution.—The constitution of fumaric

and maleic acids is discussed under FUMARIC ACID, vol. ii. p. 585. The anomalous formula $\text{CO}_2\text{H.C.C}_2\text{H}_2\text{CO}_2\text{H}$ for maleic acid, based on the formula $\text{CO}_2\text{H.C.CBr}_2\text{C}_2\text{H}_2\text{CO}_2\text{H}$, is rendered improbable by the observation that bromo-fumaric and not pyruvic acid is the product formed, together with CO_2 , when barium iso-di-bromo-succinate is treated with moist Ag_2O in the dark (Demuth a. V. Meyer, *B.* 21, 264). Racemic acid is formed when silver iso-di-bromo-succinate is boiled with water. The representation of maleic and fumaric acids by formulae in space has been discussed by Wislicenus in his treatise *Ueber die räumliche Anordnung der Atome in organischen Moleculen*.

References.—AMIDO-, BROMO-, and CHLORO-MALEIC ACIDS.

Allo-maleic acid v. FUMARIC ACID.

MALEO-FLUORESCIN $\text{C}_{16}\text{H}_{12}\text{O}_8$ i.e.

with maleic anhydride (Lunge a. Burckhardt, *B.* 17, 1598). Small needles. Sol. alcohol, sl. sol. water. Dissolves in alkalis to a red solution, with a strong green fluorescence. With KOH , MeI , and MeOH it gives a dimethyl derivative, $\text{C}_{16}\text{H}_{16}\text{Me}_2\text{O}_8$, crystallising in red needles. AcCl in HOAc gives $\text{C}_{16}\text{H}_{16}\text{Ac}_2\text{O}_8$, crystallising from HOAc in yellowish needles, insol. water, CHCl_3 , and benzene, sl. sol. alcohol (Burckhardt, *B.* 18, 2864).

MALEYL CHLORIDE v. Chloride of FUMARIC ACID.

MALIC ACID $\text{C}_4\text{H}_6\text{O}_5$ i.e.

$\text{CO}_2\text{H.CH}_2\text{CH}(\text{OH}).\text{CO}_2\text{H}$. Mol. w. 134. [100°]. S.G. 1.56 (Schröder, *B.* 12, 1611). S.G. of solutions (Schneider, *A.* 207, 262). Heat of solution—3148. Heat of neutralisation 24,919 (Gal a. Werner, *Bl.* [2] 46, 803). $[\alpha]_D = -3$ in dilute solutions; as the liquid becomes more concentrated it approaches +5.9.

Occurrence.—Malic acid was discovered by Scheele in 1785, but its composition was first correctly determined by Liebig (*A.* 26, 166). It is very widely diffused in the vegetable kingdom, being contained in plants sometimes in the free state, sometimes in the form of potassium, calcium, or magnesium salt. It is found in abundance, together with citric acid, in unripe apples, in the fruits of the barberry, sloe, elder, and mountain ash, and in gooseberries, cherries, bilberries, strawberries, raspberries, and many other fruits. It is likewise found in the roots of marsh-mallow, angelica, aristolochia, bryony, liquorice, primrose, and madder; in carrots and potatoes; in the leaves and stems of aconite, belladonna, hemp, celandine, holy thistle, lettuce, tobacco, poppy, rue, sage, house-leek, tansy, thyme, valerian, and melilot; in the flowers of chamomile, elder, and mullein; in pine-apples and grapes; in the seeds of caraway, cummin, parsley, anise, flax, and pepper; in asafoetida, opoponax, and myrrh. It also occurs in the leaves of the common ash (Gintl, *Z.* [2] 6, 377), and in the fruit of the sumach (Reinsch, *Z.* 1866, 221). Yolk, the sweat of sheep, contains potassium malate to the extent of 2.5 p.c. of the solid residue (Buisine, *C. R.* 106, 1426).

Formation.—1. Malic acid, with the same

optical properties as those with which it exists in plants, may be formed from asparagine or active aspartic acid by treatment with nitrous acid (Piria, *A. Ch.* [3] 22, 160).—2. Malic acid, with a rotatory power equal and opposite to that contained in plants, may be obtained from ordinary tartaric acid by the action of phosphorus, iodine, and water (Dessaignes, *A.* 117, 134; Bremer, *Bl.* [2] 25, 6; *B.* 8, 861, 1594).

Preparation.—1. The juice of mountain-ash berries, not quite ripe, after being pressed, boiled *tip*, and filtered, is partly neutralised with carbonate of potassium, leaving, however, a sufficient excess of acid to redden litmus pretty strongly; then precipitated by nitrate of lead; set aside for a few days, till the curdy precipitate is completely converted into small needles; these crystals freed from the admixed mucous or flocculent compound of lead oxide and colouring matter by careful elutriation with cold water, are, lastly, well washed with water. The needles of impure malate of lead are boiled with a slight excess of dilute sulphuric acid; the filtrate divided into two equal portions; one portion exactly neutralised with ammonia; the other portion then added, and the reddish liquid evaporated and cooled; it then yields nearly colourless crystals of acid malate of ammonia, which may be refiltered quite colourless by recrystallisation. These crystals are then precipitated by acetate of lead, and the precipitate, after thorough washing, is decomposed by sulphydric or sulphuric acid (Liebig).—2. The juice is boiled for some time with milk of lime in quantity not quite sufficient for neutralisation, and the pp. poured into a boiling mixture of HNO_3 (1 pt.) and water (10 pts.). The acid calcium malate which crystallises out on cooling is recrystallised from water, dissolved in water, ppd. by lead acetate, and the lead malate decomposed by H_2S (Liebig, *A.* 88, 259). By similar processes malic acid may be obtained from house-leek, from cherries or barberries, from the berries of *Rhus coriaria*, from the stems of rhubarb, from apples, and from tobacco.

Properties.—The aqueous solution, concentrated to a syrup and left to evaporate in a warm place, yields groups of colourless shining needles or prisms of 4 or 6 faces. They melt at 83° (Pelouze) or 100° (Pasteur), and do not suffer any loss of weight at 120° . They deliquesce in the air, and are v. e. sol. water and alcohol. Dilute solutions of malic acid are levorotatory, but the rotation changes so rapidly with concentration that concentrated solutions are dextrorotatory. These dextrorotatory solutions are rendered levorotatory by the addition of H_2SO_4 or of HOAc . $[\alpha]_D = 5.891 - .0895c$ (where c = percentage of water in solution) (Schneider, *A.* 207, 268). Solutions of sodium malate containing about 54 pts. of the salt to 46 pts. of water are inactive at 20° ; stronger solutions are levorotatory, while more dilute solutions are dextrorotatory (Thomson, *J. pr.* [2] 35, 153). Malic acid kills algae (*Zygnemaceæ*) (Loew & Bokorny, *J. pr.* [2] 80, 272). Malic acid prevents the ppn. of cupric and ferric salts by alkalis; 2 mols. holding 1 mol. of CuO in solution (Hotmeister, *A.* 189, 27; cf. Jette, *Fr.* 7, 489). A dilute solution of malic acid or of a malate is not immediately ppd. by lime-water or by CaCl_2 either in

the cold or on heating; but on the addition of alcohol a white pp. of calcium malate separates (Braconnot, *A. Ch.* [2] 51, 331; H. Rose, *P.* 31, 210). However, a solution of malic acid (1 mol.) mixed with pure milk of lime (2 mols.) may solidify to a pasty mass (Iwig & Hecht, *A.* 238, 171). A concentrated solution of an alkaline malate is ppd. by CaCl_2 , but presence of NH_4Cl hinders the ppn., which, however, takes place on adding alcohol. Lead acetate gives a white pp., soluble in excess of malic acid and in ammonia; when the pp. is heated in the mother-liquid it melts to a semifluid translucent mass. Malates are not blackened by heating with fuming H_2SO_4 . Dilute HOAc at 60° dissolves lead malate, but not lead tartrate or citrate (Hartsen, *Fr.* 14, 373; *Ar. Ph.* [3] 6, 110). Malic acid may be separated from oxalic and tartaric acids by ppg. the latter with CaCl_2 , filtering, and ppg. calcium malate by adding alcohol to the filtrate (Barfoed, *Fr.* 7, 403). Ammonium malate may be separated from ammonium citrate, tartrate, and oxalate by solution in alcohol (Barfoed).

Reactions.—1. Heated for some hours at 140° it yields water and fumaric acid. At 180° it gives off water and maleic anhydride, while fumaric acid remains as a solid residue. If the malic acid be suddenly heated to 200° and kept at that temperature a comparatively large quantity of maleic anhydride is obtained. The maleic anhydride, combining with the water in the distillate, is partially converted into maleic acid. Malic acid is carbonised when suddenly exposed to a red heat.—2. By treatment with potash and bromine, bromoform is obtained (Caours, *A. Ch.* [3] 19, 507).—3. Nitric acid easily oxidises it to oxalic acid and CO_2 .—4. Conc. HIAg at 180° reduces it to succinic acid (Schmitt, *A.* 114, 106). Succinic acid is also formed when calcium malate is fermented in contact with yeast (Piria, *A.* 70, 102; Liebig, *A.* 70, 104, 363). Fermentation of calcium malate by certain *Schizomycetes* produces succinic, acetic, butyric, and propionic acids and ethyl alcohol (Fitz, *B.* 11, 1896; 12, 481; cf. Dessaignes, *C. R.* 28, 16; Liebig, *A.* 70, 104, 363; Kohl, *A.* 78, 252; Baer, *Ar. Ph.* [2] 69, 147; Winckler, *Jahrb. pr. Pharm.* 22, 300; Rebling, *Ar. Ph.* [2] 67, 300; Béchamp, *C. R.* 70, 999).—5. By slow oxidation in the cold with $\text{K}_2\text{Cr}_2\text{O}_7$ it is converted into malonic acid (Dessaignes, *A.* 107, 251).—6. When boiled in dilute aqueous solution with MnO_2 it yields a distillate containing aldehyde (Liebig, *A.* 113, 14).—7. Heated with KOH it yields acetic and oxalic acid.—8. When calcium malate (1 pt.) is heated with PCl_5 (4 pts.) the chloride of fumaric acid passes over (Perkin & Duppa, *A.* 112, 24; Lié-Bodart, *A.* 100, 327).—9. Boiling aqueous H_2SO_4 at 185° gives aldehyde, CO_2 , water, and CO (Weith, *B.* 10, 1744).—10. The electrolysis of potassium malate gives aldehyde, CO_2 , and some acetic acid (Bourgoin, *Bl.* [2] 9, 427).—11. Water containing a few drops of H_2SO_4 at 160° gives fumaric acid (Malkownikoff, *A.* 182, 351).—12. When heated with phenol and H_2SO_4 it gives

—13. Long boiling with conc. HClAq gives fumaric acid.—14. Conc. HBr at 100° gives bromo-succinic acid and fumaric acid (Kekulé,

A. 180, 11).—15. *Chiral* at 125° forms $\text{O} \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$
 $\text{CO}_2\text{H} \cdot \text{CH} \cdot \text{O} \cdot \text{OO}$ [140°]. This forms

large crystals, al. sol. cold water (Wallach, A. 193, 42). With PCl_5 it gives the oily chloride $\text{C}_4\text{H}_4\text{Cl}_4\text{O}_6$, whence alcohol forms $\text{C}_4\text{H}_4\text{Cl}_4(\text{OEt})_6\text{O}_6$ [46°], and MeOH gives $\text{C}_4\text{H}_4\text{Cl}_4(\text{OMe})_6\text{O}_6$ [85°].—16. *Phenyl hydrazine* at 120° forms $\text{C}_{16}\text{H}_{16}\text{N}_4\text{O}_6$, i.e. $\text{C}_6\text{H}_5\text{O}(\text{CO} \cdot \text{N} \cdot \text{H}_2 \cdot \text{Ph})_2$ [223°], which crystallises from dilute alcohol in plates (Bülow, A. 236, 195; cf. Fischer a. Passmore, B. 22, 2734).—17. Malic acid (3 pts.) heated with *m*-amido-benzoic acid at 150° forms a product whence by washing with hot water and alcohol, dissolving in aqueous NH_3 and ppg. by HCl, there is obtained a white powder $\text{C}_8\text{H}_8\text{O}_4(\text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H})_2$. The ammonium salt of this acid forms with cupric acetate a pp. of $\text{Cu}_2(\text{C}_8\text{H}_8\text{N}_4\text{O}_{10})_2$. AcO decomposes it, forming $\text{NHAc} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ (Schiff, G. 16, 28; A. 232, 166).

Salts.—Malic acid has a tendency to form acid salts. At 200° the salts give off water and are converted into fumarates.— $\text{NH}_4\text{HA}''$: transparent trimetric prisms. Not hemihedral, but becomes so after fusion and recrystallisation. S.G. 1.55. S. 32 at 157°. $[\alpha]_D = -6^\circ$. On dry distillation it forms fumarimide, fumaric, and maleic acids, and active and inactive malic acid. Combines with acid ammonium tartrate. Normal ammonium malate $(\text{NH}_4)_2\text{A}''$ is v. c. sol. water, and its solution gives off NH_3 to the air, becoming acid. In a solution containing 63 p.c. of the salt $[\alpha]_D = -4.2$. In a 17 p.c. solution $[\alpha]_D = -7.2$ (Schneider, A. 207, 276).— KHA'' : crystals. Begins to decompose at 100°. Sol. water, insol. alcohol. $[\alpha]_D = -5$ in a 21 p.c. solution; $= -5.7$ in a 9.4 p.c. solution at 20°.— $\text{K}_2\text{A}''$: Uncrystallisable and deliquescent mass. $[\alpha]_D = -2.2$ in a 62 p.c. solution; $= -6.8$ in a 9.4 p.c. solution at 20° (Schneider).— NaHA'' : Crystallisable and permanent in the air; sol. water, insol. alcohol. $[\alpha]_D = +0.15$ in a 60.6 p.c. solution; $= -5.64$ in a 20 p.c. solution at 20° (Schneider).— $\text{Na}_2\text{A}''$: Uncrystallisable. $[\alpha]_D = +4.7$ in a 65.5 p.c. solution; $= -8.4$ in a 5.8 p.c. solution.— LiHA'' : Uncrystallisable. $[\alpha]_D = -4.6$ in a 50 p.c. solution; $= -8.4$ in a 10 p.c. solution.— $\text{Li}_2\text{A}''$: Uncrystallisable. $[\alpha]_D = -4.1$ in a 39 p.c. solution; $= -12$ in a 6 p.c. solution at 20° (Schneider, A. 207, 273).— BaA'' : thin plates. $[\alpha]_D = +8.2$ in a 9.4 p.c. solution; $= -2.6$ in a 9 p.c. solution at 20°.— $\text{BaH}_2\text{A}''$: Uncrystallisable and more soluble than the neutral salt.— SrA'' : (dried at 100°). Crystalline mass, v. sol. water.— $\text{SrH}_2\text{A}''$: Crystalline pp. formed by adding malic acid to a solution of the preceding. Sl. sol. cold, m. sol. hot, water.— CaA'' : 3aq. S. 839 at 15°; 711 at 45°; 566 at 58°; 600 at 65°; 663 at 72°; 737 at 86° (Iwig a. Hecht, A. 233, 170). Granular crystalline mass. When a solution of malic acid is added to lime water a pasty mass of $\text{A}''\text{Ca}_2(\text{OH})_2$ 3aq (?) is first formed, but when the theoretical quantity of malic acid has been added this dissolves up again, and the clear liquid deposits nodules of CaA'' 3aq in the course of 24 hours.— $\text{CaH}_2\text{A}''$: 6aq (Hagen, A. 88, 263). Occurs in stems of *Geranium zonale*, the berries of *Rhus glabrum* (Rogers, Am. S. 27, 294), and in tobacco. Separates in well-formed trimetric

octahedra from a solution of the neutral salt in warm dilute nitric acid. S. (of $\text{CaH}_2\text{A}''$) 1287 at 15°; 8514 at 45°; 32236 at 57°; 13127 at 68°; 7437 at 78° (I. a. H.). $[\alpha]_D = +5$ (Brömer, R. T. C. 3, 164). When the solution obtained by neutralising malic acid with CaCO_3 is boiled a nearly insoluble granular pp. is got, which consists of CaA'' 3aq (Richardson a. Meunier, A. 20, 135), or of CaA'' (Hagen, A. 38, 257).— MgA'' 5aq. Prisms, which separate from a highly concentrated solution (Liebig, A. 5, 148). Alcohol ppts. MgA'' .— $\text{MgH}_2\text{A}''$ 4aq (or 3aq). Flattened prisms.— ZnA'' 3aq. Monoclinic crystals (Handl, J. 1859, 289). Slowly deposited in the cold from the product of solution of zinc carbonate in aqueous malic acid at 30°. When these substances are boiled together a basic salt $\text{ZnO}(\text{ZnA}'')$ 4aq is deposited as a jelly, changing to a sandy powder, while the filtrate deposits ZnA'' 3aq as hard, four-sided prisms. S. 1.7 at 20°.— $\text{ZnH}_2\text{A}''$ 2aq. Elongated octahedra. S. 4 in the cold.—The neutral manganese salt is very soluble and uncrystallisable; by adding malic acid to its solution the acid salt is ppd. as a white powder, S. 2.5. From boiling water it separates in rose-coloured crystals.—The neutral and acid ferric salts are gummy masses, v. sol. water and alcohol.— CuA'' 3aq: green gummy mass, v. sol. water.— $\text{CuH}_2\text{A}''$ 2aq: blue crystals, obtained by evaporation at 40°.— $\text{CuO}(\text{CuA}'')$ 4aq: green insoluble powder obtained by boiling aqueous malic acid with cupric carbonate. If evaporated at 45° dark-green crystals of $\text{CuO}(\text{CuA}'')$ 6aq may be got. H. Schulze (dr. Ph. [2] 57, 273) obtained green crystals of a double salt of cupric malate and ammonium sulphate.— PbA'' 3aq. Obtained by ppg. neutral lead acetate with a solution of calcium or potassium malate, as a white curdy pp., which slowly changes to radiating four-sided needles. Melts in boiling water. V. sl. sol. cold, m. sol. boiling, water, from which it is deposited in needles. Dissolves easily in nitric acid; acetic and malic acids do not dissolve it more readily than water. When dry it does not melt at 170° but at 220° it forms lead fumarate.— PbA'' 3aq (dried at 100°) (Otto, A. 127, 175).— $\text{PbO}(\text{PbA}'')$: Obtained by digesting the neutral salt with ammonia, or by dropping a solution of a neutral malate into a boiling solution of lead subacetate. Amorphous pp., not becoming crystalline. Does not melt under water. Melts under hot dilute HOAc , evidently changing to the neutral salt. Nearly insol. water, to which, however, it imparts an alkaline reaction.— $\text{Ag}_2\text{A}''$: White granular pp., formed by adding silver nitrate to a solution of neutral or acid ammonium malate.—Aniline malate $\text{C}_6\text{H}_5\text{NH}_2\text{HA}''$ [144°]. White prisms (from alcohol). On dry distillation it gives water, aniline, the phenyl-imide of phenyl-aspartic acid [211°], and the phenyl-imide of malic acid [91°] (Anschütz a. Wirtz, Am. 9, 337; A. 239, 140).

Acetyl derivative $\text{C}_4\text{H}_4(\text{OAc})(\text{CO}_2\text{H})_2$ [132°]. From the acetyl derivative of the anhydride and water (Anschütz, A. 254, 165).

Di-methyl ether $\text{Me}_2\text{A}''$. (122° at 10 mm.).

S.G. 1.2886. Formed, together with MeHA'' ,

by passing HCl into a cooled solution of malic acid in MeOH (Demondésir, A. 80, 801; O. R.

23, 227; Anschütz, *B.* 14, 2790; 18, 1953).— $\text{Ca}(\text{MeA})_2$ is sol. alcohol.

Acetyl derivative of the di-methyl ether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Me})_2$. (129° at 11 mm.). From the ether and AcCl .

Di-ethyl ether $\text{Et}_2\text{A}''$. (128° at 10 mm.). Formed in like manner. Can only be distilled in *vacuo*.— $\text{Ca}(\text{EtA})_2$ is sol. alcohol.

Acetyl derivative of the di-ethyl ether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Et})_2$. (137° at 12 mm.).

Nitroxy derivative of the di-ethyl ether $\text{C}_2\text{H}_5(\text{ONO}_2)(\text{CO}_2\text{Et})_2$. S.G. 1.202. From the ether, fuming HNO_3 , and conc. H_2SO_4 (Henry, *B.* 3, 532). Thick oil.

Di-n-propyl ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{Pr})_2$. (151° at 10 mm.). (Anschütz).

Acetyl derivative of the di-n-propyl ether $\text{C}_2\text{H}_5(\text{OAc})(\text{CO}_2\text{Pr})_2$. (157° at 12 mm.).

Mono-isoamyl ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CO}_2\text{C}_4\text{H}_9)$. From malic acid and isoamyl alcohol at 120° (Breunlin, *A.* 91, 323).— $\text{NH}_4\text{A}'$: needles.— CaA'_2 : plates.

Acetyl derivative of the anhydride $\text{CH}(\text{OAc})\text{CO}$.

$\text{CH}_2\text{—CO}$ O . [54°]. (161° at 14 mm.).

Formed, together with malic anhydride, by heating malic acid with AcCl (Anschütz, *B.* 14, 2791). Decomposed by distillation under atmospheric pressure into HOAc and maleic anhydride.

Amide $\text{C}_2\text{H}_5(\text{OH})(\text{CONH}_2)_2$. *Malamide*. When gaseous NH_3 is passed into an alcoholic solution of malic ether crystals of malamide are deposited. Separates from water in well-defined crystals. Resolved by hydrolysis into NH_3 and malic acid.

Amic ether $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{Et})(\text{CONH}_2)_2$. *Malamic ether*. Formed as a crystalline mass when gaseous NH_3 is passed into malic ether (Pasteur, *J.* 1853, 411).

Di-anilide $\text{C}_2\text{H}_5(\text{OH})(\text{CONHPh})_2$. [175°]. Formed, together with the phenyl-imide, by boiling aniline (2 mols.) with malic acid (1½ mols.). The phenyl-imide is extracted by boiling water, and the residue recrystallised from alcohol, using animal charcoal (Arppe, *A.* 96, 106). Colourless scales. Nearly insol. water, dilute acids, and alkalis.

Mono-anilide $\text{C}_2\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CONHPh})_2$. *Malanilic acid*. [145°]. Obtained by boiling the phenyl-imide with aqueous ammonia; the product is ppd. by baryta, and the Ba salt decomposed by H_2SO_4 , avoiding any excess. White granules composed of very minute needles (from alcohol); v. sol. water, m. sol. alcohol, sl. sol. ether. Reddens litmus. Hot dilute H_2SO_4 resolves it into water and the phenyl-imide. Its salts are soluble in water.— AgA' : white pp., crystallising from water in shining scales.

Phenyl-imide $\text{C}_2\text{H}_5(\text{OH})\text{COCONHPh}$. [170°]. Formed by heating malic acid with aniline and crystallising from water. Groups of delicate needles; v. sol. water, alcohol, and ether.

Inactive malic acid $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}$. [c. 108°] (Pictet, *B.* 14, 2648); [c. 114°] (Kekulé); [188°] (Pasteur; Loyd; Bischoff). Occurs as calcium salt in the leaves of the common ash (*Fraginus excoecior*) (Gintl, *J.* 1868, 800; Garot, *J.* 1853, 409).

Formation.—1. By mixing equal parts of *levo*- and *dextro*-malic acids (Van't Hoff, jun., *B.* 18, 2170; *R. T. C.* 4, 130).—2. By reducing racemic acid with HIAg (Bremer, *Bl.* [2] 45, 6).—3. By the action of nitrous acid on inactive aspartic acid obtained from fumarimide (Pasteur, *A. Ch.* [3] 84, 46; *A.* 82, 330).—4. By the action of moist Ag_2O on bromo-succinic acid (Kekulé, *A.* 117, 126; 130, 24).—5. By heating fumaric acid with a large quantity of water at 150°–200° (Jungfleisch, *Bl.* [2] 30, 147).—6. By heating fumaric acid (1 pt.) with NaOH (4 pts.) and water (40 pts.) for 100 hours at 100° (Linne-mann a. Loyd, *A.* 192, 80; *B.* 9, 925).—7. Together with fumaric acid, by treating di- β -chloropropionic ether with a weak alcoholic solution of KC_2 , and boiling the product with potash (Werigo a. Tanatar, *A.* 174, 367). Also in like manner from di- β -bromopropionic acid (Tanatar, *B.* 13, 160).—8. From chloro-ethanetri-carboxylic ether $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CCl}(\text{CO}_2\text{Et})_2$, and dilute alcoholic KOH (Bischoff, *A.* 214, 49).

Properties.—Crystallises more readily than active malic acid, being less soluble in water and not deliquescent, or at any rate less deliquescent than the active acid. V. s. sol. water, v. sol. alcohol, v. sl. sol. ether. When heated at 200° it yields fumaric acid.

Salts.— $\text{NH}_4\text{HA}''$: trimetric crystals (Van't Hoff).— $\text{NH}_4\text{HA}'$: monoclinic crystals. *ac:b* = 5856:1:5377; β = 68° 12'.— CaA'' : granular pp.; sl. sol. water.— CaA' ag.— CaA''_2 ag: nodules of transparent crystals (Pasteur). The acid calcium salt resembles that of the active acid except that its crystals exhibit hemihedral faces. The lead salt melts under water, but crystallises less easily than the inactive salt. The lead salt obtained by Tanatar from di-bromopropionic acid did not melt under water.— AgA' .

By crystallising the cinchonine salt Bremer (*B.* 13, 352) was able to separate it into salts of *levo*- and *dextro*-malic acid.

Ethyl derivative $\text{C}_2\text{H}_5(\text{OEt})(\text{CO}_2\text{H})_2$. [86°]. Obtained by saponifying its di-ethyl ether (Purdie, *C. J.* 39, 348). Transparent crystals (from ether), sol. water. Not ppd. by lead subacetate, but in neutral and feebly acid solution it is ppd. by lead nitrate and, more slowly, by neutral lead acetate. Fuming HCl at 120° reduces it to succinic acid.— CaA'' : insoluble.— AgA'' : sl. sol. water.— BaA'' ag: hygroscopic; v. sol. water.

Di-ethyl ether of the ethyl derivative $\text{C}_2\text{H}_5(\text{OEt})(\text{CO}_2\text{Et})_2$. (195°–200°) at 250 mm ϕ . From fumaric ether and NaOEt , the product being neutralised (Purdie).

Isobutyl derivative $\text{C}_2\text{H}_5(\text{OC}_4\text{H}_9)(\text{CO}_2\text{H})_2$. Crystalline, deliquescent mass (Purdie).— CaA' : insol. water.— $\text{Ag}_2\text{A}'$: flocculent, insol. water.

The following compounds are probably also derivatives of the same inactive malic acid:—

Amic acid $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CONH}_2$. *Malamic acid*. [146°]. Obtained, together with its ether, by boiling the amide of diazo-succinic ether with water (Curtius, *J. pr.* [2] 86, 470). Colourless prisms; v. sol. water, alcohol, and ether.

Methyl ether of the amic acid $\text{CO}_2\text{Me}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CONH}_2$. [105°]. Formed,

together with methyl fumarate, by boiling methyl diazo-succinamate

$\text{CO}_2\text{Me} \cdot \text{CH}_2 \cdot \text{CN}_2 \cdot \text{CONH}_2$, with slightly acidified water (Curtius, *J. pr.* [2] 38, 482). Silky plates; v. s. sol. alcohol, ether, and water. With benzoic acid at 150° it forms crystalline $\text{CO}_2\text{Me} \cdot \text{CH}(\text{OBz}) \cdot \text{CONH}_2$ [80°]; v. sol. ether.

Benzoyl derivative of the ethyl ether of the amic acid $\text{CO}_2\text{Et} \cdot \text{CH}_2 \cdot \text{CH}(\text{OBz}) \cdot \text{CONH}_2$. [97°]. Formed by heating ethyl diazo-succinamate with HOBz at 145°. Colourless rhombohedra.

Dextro-malic acid $\text{CO}_2\text{H} \cdot \text{CH}_2 \cdot \text{CH}(\text{OH}) \cdot \text{CO}_2\text{H}$. [c. 100°]. Formed from dextro-asparagine (from sprouting vetch seeds) by treatment with nitrous acid (Piutti, *B.* 19, 1693). The cinchonine salt is obtained by crystallisation from the cinchonine salt of inactive malic acid. Resembles ordinary malic acid, except that it is dextrorotatory.

Isomeride of malic acid $\text{C}_4\text{H}_6\text{O}_5$. [155°-168°]. Formed by heating acetylene dibromide (5 pts.) with KCy (4 pts.) and alcohol (28 pts.) at 100°, and saponifying the resulting nitrile with potash (Sabanejeff, *A.* 216, 275). Crystals; v. sol. water.— $\text{Ag}_2\text{A}''$.

Isomalic acid of Kümmerer (*J. pr.* 88, 321; *A.* 139, 257) is identical with citric acid (Ostwald, *B.* 21, 3534).

Paramalic acid is described as **DIGLYCOLLIC ACID**.

Iso-malic acid $\text{CH}_2 \cdot \text{C}(\text{OH})(\text{CO}_2\text{H})_2$. [c. 140°]. From bromo-iso-succinic acid and moist Ag_2O (Schmöger, *J. pr.* [2] 14, 77; 19, 168; 21, 38). Crystals; v. sol. water, alcohol, and ether. At 170° it splits up into CO_2 and lactic acid. Inactive. Its neutral solutions give no pp. with CaCl_2 (unlike methyl-tartronic acid, which gives a pp. on warming).— BaA'' 2aq: amorphous pp. S. 1 at 100°. Loses its water of crystallisation at 130° (unlike methyl-tartronic acid).— PbA'' . Does not melt under water.— $\text{Ag}_2\text{A}''$: needles.

Methyl-tartronic acid $\text{CH}_2 \cdot \text{C}(\text{OH})(\text{CO}_2\text{H})_2$. [178°]. Obtained from pyruvic acid by addition of KC_2 and HCl , the product being boiled with baryta-water (Böttlinger, *B.* 14, 148; 17, 144). Rhombohedral crystals. Decomposes on fusion, giving off CO_2 . Boiling conc. HClAq splits it up into CO_2 and lactic acid.— BaA'' aq (dried at 130°). Heavy crystalline powder, ppd. on boiling.— ZnA'' 2aq: crystalline powder.— $\text{Ag}_2\text{A}''$ aq: white crystalline powder.

Reference.—Bromo-malic acid.

MALLOTOXIN $\text{C}_8\text{H}_8\text{O}_8$, or $\text{C}_8\text{H}_{10}\text{O}_8$. May be extracted by CS_2 from finely-divided kamala, a yellow dye got from the seeds of *Mallotus Phillippensis* (A. G. Perkin a. W. H. Perkin, jun., *B.* 19, 8109). Flesh-coloured needles; insol. water, v. sol. hot alcohol. Dissolves readily in alkalis, forming a yellowish-red solution. Ac_2O yields a di-acetyl derivative, *r. ROTTERLIN*.

MALOBIBRIC ACID $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$, i.e.

$\text{OO} \langle \text{NH} \cdot \text{CO} \rangle \text{CH} \cdot \text{CO} \cdot \text{NH}_2$ (?). Formed, as ammonium salt, by heating barbituric acid (malonyl-urea) with urea at 160° (Baeyer, *A.* 135, 312). Formed also by boiling cyanuromalic acid with HClAq (Nencki, *B.* 5, 888). Ppd. by adding HCl to solutions of its salts as a granular pp., which, when quite pure, can be obtained in crystals. Dissolves completely in bromine and

water, forming di-bromo-barbituric acid. Nitric acid converts it into nitro-barbituric (dilituric) acid.— KA'' aq: long needles. S. 16 in hot water.

MALONAMIC ACID *v.* MALONIC ACID.

MALONAMIDE *v.* Amide of MALONIC ACID.

MALONANILIC ACID *v.* Mono-anilide of MALONIC ACID.

MALONIC ACID $\text{C}_2\text{H}_2\text{O}_4$, i.e. $\text{CH}_2(\text{CO}_2\text{H})_2$. *M.A.* w. 101. [134°] (Krafft a. Noerdlinger, *B.* 22, 816). S. 109 at 1°; 138 at 16° (Miczynski, *M.* 7, 258); 109 at 15° (Bourgoin, *Bl.* [2] 33, 423). H.F. 212,700 (Stohmann, Kleber a. Langbein, *J. pr.* [2] 40, 206). H.C. v. 207,900. H.C. p. 207,300 (S., K. a. L.); 208,650 (Lougouine, *C. R.* 107, 597). *Heat of solution* = -4573. *Heat of neutralisation* by NaOH 27,120 (Gal a. Werner, *Bl.* [2] 46, 803); 26,650 (Massol); by KOH 27,300; by NH_3 25,040; by $\text{BaO}_2 \cdot \text{H}_2\text{O}$ 30,135; by $\text{CaO} \cdot \text{H}_2\text{O}$ 27,090 (Massol, *C. R.* 107, 257, 393; 108, 813, 1060; 109, 27). S.I.L. (0° to 50°) -2832; (0° to 110°) -3262 (Hess, *P.* [2] 35, 410).

Occurrence.—In beet-root (Lippmann, *B.* 14, 1183).

Formation.—1. Discovered by Dessaignes (*C. R.* 47, 76) as a product of the slow oxidation of malic acid by cold aqueous $\text{K}_2\text{Cr}_2\text{O}_7$.—2. By the action of alkalis or acids on cyano-acetic acid (semi-nitrile of malonic acid) or cyano-acetic ether (Kolbe, *A.* 131, 349; Hugo Müller, *C. R.* 17, 109).—3. By oxidation of allylene or propylene with cold alkaline KMnO_4 (Berthelot, *J.* 1867, 335).—4. By boiling barbituric acid with potash (Baeyer, *A.* 130, 143; Heinzel, *A.* 139, 129).—5. By boiling mucobromic acid with baryta-water (Jackson a. Hill).—6. From di-chloro-acrylic ether by treatment with Ag_2O at 125°, and saponifying the product (Wallach a. Hunsauer, *A.* 193, 25). 7. By treating $\text{CBr}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CBr}_3$ with fuming HNO_3 (Denole, *B.* 11, 1714).

Preparation.—1. From ethylic, or better from potassic, chloro-acetate. Chloro-acetic acid (100 g.) dissolved in water (200 g.) is neutralised by K_2CO_3 (75 g.), mixed with KC_2 (70 g.), and warmed. The reaction heats the liquid to boiling and is soon over. KOH (100 g.) is now added, and the liquid boiled as long as NH_3 escapes. The liquid is then acidified with HCl , evaporated to dryness, and the malonic acid extracted by ether (H. v. Miller, *J. pr.* [2] 19, 326; cf. Finkelstein, *A.* 133, 338).—2. Chloro-acetic acid (100 pts.) is dissolved in twice its weight of water, and neutralised with potassium carbonate (75 pts.). To the solution is added 75 to 80 pts. potassium cyanide (98 p.c.), and the mixture heated for two hours, with continual renewal of the evaporated water. The remaining mass is decomposed with concentrated potash. When the odour of ammonia has disappeared the solution is neutralised with hydrochloric acid, and ppd. as a calcium salt. This is decomposed with the requisite quantity of oxalic acid, the residue extracted with ether, and the solution evaporated (Conrad, *A.* 204, 121).—3. By dissolving chloro-acetic acid (100 gms.) in double its weight of water, saturating the solution with potassium bicarbonate (110 gms.), adding potassium cyanide (75 gms.), and warming on the water-bath. At the end of the reaction double the volume of concentrated hydrochloric acid is added and the precipitation of potassium chloride rendered complete by passing in a current of HCl gas. The

potassium and ammonium chlorides are filtered off, and the filtrate evaporated. The nearly dry residue is taken up with ether, which on evaporation yields pure malonic acid (70 gms.) (Bourgoin, *A. Ch.* [5] 20, 271).—4. Chloro-acetic ether is boiled with pure KCl dissolved in 70 p.c. alcohol for 4 hours. The alcohol is distilled off, and the residue mixed with dilute HCl and evaporated to dryness. The cyano-acetic ether is extracted with ether and decomposed by fuming HClAq at 100° (Patrieff, *J. R.* 10, 64; *B.* 7, 400).—5. In like manner from bromo-acetic ether (Franchimont, *B.* 7, 216).

Properties.—Triclinic laminae or prisms. Decomposes a little over its melting-point into CO₂ and acetic acid, but when heated under 10 mm. pressure it may be sublimed. V. sol. water, alcohol, and ether. When heated with Ac₂O, malonic acid gives a reddish-yellow liquid with greenish-yellow fluorescence:—0.01 g. is sufficient for this test (Kleemann, *B.* 19, 2030). A small quantity of malonic acid treated with urea and POCl₃ yields a product which when evaporated with nitric acid leaves a residue which gives with ammonia the purple colour due to murexide (Grimaux, *C. R.* 88, 85).

Reactions.—1. A solution of the free acid is hardly affected by the passage of an electric current. But the electrolysis of a concentrated alkaline solution gives off oxygen, CO, and CO₂ at the positive pole, without any hydrocarbon (von Miller; Bourgoin, *A. Ch.* [5] 20, 80; *C. R.* 90, 608).—2. Malonic acid (5 g.) heated with bromine (10 c.c.) and water (12 c.c.) for 18 hours at 120° to 145° gives bromoform, tri-bromo-acetic acid, CO₂, and HBr (Bourgoin, *Bl.* [2] 34, 215).—3. HNO₃ (S.G. 1.53) in the cold gives off CO₂ (2 mols.) (Franchimont, *R. T. C.* 3, 422).—4. PCl₅ gives malonyl chloride and a compound C₂H₂ClO₂, crystallising in needles [122°], decomposed by water and alcohol with evolution of CO₂ (Béhal a. Augur, *Bl.* [2] 50, 631).—5. Malonic acid (1 pt.), NaOAc (1 pt.), and Ac₂O (3 pts.) at 100° forms a brownish-yellow acid C₁₀H₈O₆. The sodium salt C₁₀H₇NaO₆ is v. sol. water, alkaline, and conc. H₂SO₄, m. sol. HOAc. Its solutions exhibit fluorescence, but on heating CO₂ is evolved and the fluorescence disappears. An acetic acid solution of the salt C₁₀H₇NaO₆ boiled with a solution of phenyl-hydrazine acetate forms CO₂, NaOAc, and C₁₀H₇O₆(N.NHPh)₂, a substance insol. water and ether, v. sol. alcohol and HOAc, forming a green solution in conc. H₂SO₄, and melting with decomposition about 180° (Kleemann, *B.* 19, 2030).—6. *Benzoic aldehyde* and HOAc forms benzylidene-malonic acid C₆H₅.CH:CH(CO₂H)₂.—7. *Propionic aldehyde* and HOAc gives CH₃.CH₂.CH:CH.CO₂H (Komnenos, *A.* 218, 168).—8. *o-Oxy-benzoic aldehyde* and HOAc at 100° forms coumarin-carboxylic acid (vol. ii. p. 269).—9. *Cinnamic aldehyde* and HOAc at 100° gives phenyl-butenene dicarboxylic acid C₆H₅.CH:CH.CH:CH(CO₂H)₂ (Stuart, *C. J.* 49, 866).—10. Heated with *phenyl thiocarbimide* it gives acetanilide and the dianilide of malonic acid (Moine, *Ann. Chim. Farm.* [4] 4, 201).

Salts.—The salts, with the exception of those of the alkali metals, are sparingly soluble in water, more soluble in dilute malonic acid, HOAc, or nitric acid (Finkelstein, *A.* 133, 888).—NaHA"aq: well-defined crystals (F.).—

NaHA"aq: trimetric prisms (Shadwell, *J.* 1881, 699).—Na₂A"aq (Mulder, *Bl.* [2] 29, 532; cf. Massol, *C. R.* 107, 393).—KHA"aq: prisms.—KHA"aq: monoclinic prisms (Haushofer, *J.* 1881, 699).—K₂A"2aq: deliquescent monoclinic crystals. Gives CO₂ and hydrogen on electrolysis (H. von Miller).—K₂A"aq: monoclinic prisms (H.).—NH₄A": very deliquescent crystals. Heat of formation from solid malonic acid and NH₃: 22,780 (Massol, *C. R.* 108, 1060).—(NH₄)₂A": very deliquescent needles. Heat of formation from solid malonic acid and NH₃: 41,015.—BaA"2aq: bulky flocculent pp. gradually becoming crystalline. Crystallises from water in long slender needles. At 100° it loses aq, and when heated in a current of hydrogen at 140° it becomes anhydrous. BaA"aq is not dehydrated by heating in air at 150° (Pinner a. Bischoff, *A.* 179, 84). S. 14 at 0°; 20 at 18°; 32 at 70° (Miezynsky, *M.* 7, 261). Heat of solution: —3830 (Massol, *C. R.* 109, 29).—CaA"2aq: monoclinic needles (from water). Ppd. in gelatinous form on adding CaCl₂ to a solution of ammonium malonate. S. 3 at 0°; 37 at 20°; 47 at 72° (Miezynski). According to Massol (*C. R.* 108, 813) this salt separates in small brilliant scales on slow evaporation of its solution at 35°.—CaA"4aq: silky needles. Obtained by slow evaporation at 15° (Massol). V. sl. sol. water. May be dehydrated in a current of hydrogen at 135°.—SrA": small brilliant scales (Ossipoff, *C. R.* 108, 815).—MgA"2aq, MgA"aq, and MgA"3aq are described by Finkelstein as crystalline powders.—ZnA"2aq: monoclinic crystals.—MnA"2aq: trimetric prisms.—CoA"2aq: monoclinic crystals (Haushofer).—NiA"2aq: bluish-green powder.—CdA": deliquescent.—CdA"4aq: monoclinic crystals.—CdA"12aq: triclinic (Haushofer, *J.* 1882, 362).—PbA": crystalline powder, sol. HOAc.—CuA"3aq: blue triclinic crystals (H.).—Cu₂OA": bluish-green pp.—Ag₂A": crystalline pp., not blackened by boiling water.—Ethylamine salt NEt₃HA": gives at 180° water and the

whence concentrated caustic potash solution forms NH₄Et.CO.CH:CH.CO₂H [126°] (Pintti, *C. C.* 1888, 1529).

Methyl ether MeA" (181.5° cor.). S.G. 1.1603; $\frac{d}{4}$ 1.1511 (Perkin, *C. J.* 45, 509); $\frac{d}{20}$ 1.1753 (W.). M. M. 5.28 at 17°. S.V. 187.6 (Wiens, *A.* 253, 297). From silver malonate and Mel (Osterland, *B.* 7, 1286). Oil, sol. alcohol and ether.

Mono-ethyl ether CO₂Et.CH₂.CO₂H. When alcoholic ROH (1 mol.) is added to alcoholic malonic ether the liquid forms a crystalline pulp of CO₂Et.CH₂.CO₂K composed of needles (Van't Hoff, *B.* 7, 1571; Freund, *B.* 17, 780). PCl₅ converts it into CO₂Et.CH₂.COCl (170°–180°).

Ethyl ether CH₃(CO₂Et)₂ (198° cor.) (Perkin, *C. J.* 45, 509); $\frac{d}{4}$ 1.0761 (Wiens). S.G. 1.0610; $\frac{d}{20}$ 1.0525. M. M. 7.41 at 14°. S.H. 489 at 0°; 45 between 10.6° and 82.2° (R. Schiff, *Zeit. Phys. Chem.* 1, 376; *G.* 16, 464). S.V. 185.1 (Wiens, *A.* 253, 297).

Preparation.—1. Calcium malonate is boiled with H₂SO₄ and 4 times the theoretical quantity of alcohol for 24 hours (Conrad, *B.* 12, 749).—

2. Chloro-acetic acid (250 g.) is dissolved in water (500 g.) and K_2CO_3 (187 g.); KOy (175 g.) is added, and the whole heated on a sand-bath until the reaction begins. The product is evaporated until its temperature is 185° , and is then allowed to cool. When cold it is treated with two-thirds of its weight of alcohol and gaseous HCl is passed in. The product is poured into iced water, extracted with ether, dried over $CaCl_2$, and distilled (Venable a. Claisen, A. 218, 131). Tricarballic ether (287°) is obtained as a by-product (Dümmichen, C. O. 1888, 1347).

Reactions.—1. Water at 150° gives CO_2 and acetic ether (Hjelt, B. 13, 1949).—2. Boiling with *m*-amido-benzoic acid and a little alcohol forms $CH_3(CO.NH.C_6H_4.CO.H)_2$, a powder which will not melt and is insol. water, hardly sol. boiling alcohol, sol. dilute NH_4Ag , and dissolves without change in conc. H_2SO_4 (Schiff, A. 232, 143; B. 17, 403; G. 15, 534). The intermediate compound $CO_2Et.CH_2.CO.NH.C_6H_4.CO.H$ [173°] is also formed at the same time.—3. Chlorine forms chloro-malonic ether.—4. Cautious treatment with nitric acid (5 pts. of S.G. 1.6) gives nitro-malonic ether (Franchimont a. Klobbie, R. T. C. 8, 293).—5. According to Lang (B. 19, 2937) zinc methyl or zinc ethyl act in the cold, forming phloroglucin tricarboxylic ether, methane, and ethane.—6. When a mixture of malonic ether (1 mol.) and EtI (2 mols.) is heated with zinc there is formed ethane and ethyl-malonic ether (90 p.c. of the theoretical amount) (Daimler, B. 20, 203). When malonic ether (20 g.), EtI (100 g.), and granulated zinc are heated with inverted condenser at 100° there is formed di-ethyl-malonic ether (Joullowsky, J. pr. [2] 39, 446).—7. With allyl iodide and zinc there is formed di-allyl-malonic ether and propylene (Matvéeff, J. pr. 39, 452).—8. When malonic ether (2 mols.) is treated with glycolal (1 mol.) and zinc chloride it forms di-oxy-butane tetracarboxylic ether (CO_2Et), $CH_2.CH(OH).CH(OH).CH(CO_2Et)_2$ (Polonowsky, A. 246, 1).—9. With benzoic aldehyde and HCl it forms benzylidene-malonic ether $C_6H_5.CH:C(CO_2Et)_2$ (Claisen a. Cremer, A. 218, 129).—10. Furfuraldehyde and acetic anhydride give furfuryl-methenyl-malonic ether $C_4H_3O.CH:C(CO_2Et)_2$ which boils with slight decomposition at 293° , and gives on saponification the acid ether $C_4H_3O.CH:C(CO_2H)(CO_2Et)$ [102.5°], and finally the acid $C_4H_3O.CH:C(CO_2H)_2$ [187°], which may be reduced by sodium-amalgam to $C_4H_3O.CH_2.CH(CO_2H)_2$ [125°] (Marckwald, B. 21, 1081).—11. Aldehyde forms $CH_3.CH:C(CO_2Et)_2$ and $CH_3.CH:CH(CO_2Et)_2$ (Komnenos, A. 218, 145).—12. Diazobenzene chloride forms benzene-azo-malonic acid, identical with the phenyl hydrazide of mesoxalic acid (R. Meyer, B. 21, 118).

Sodium-malonic ether $CHNa(CO_2Et)_2$. Formed, with evolution of hydrogen, by dissolving sodium in malonic ether. The reaction is stopped by the crust of the sodium compound which forms on the surface of the metal; but this may be removed by adding alcohol (2 vols.) which first forms $NaOEt$, and this then reacts with the malonic ether. The sodium-malonic ether crystallises on cooling, and may be freed from alcohol by heating to 150° in a current of hydrogen (Conrad, B. 12, 750). If, however, it be required merely for synthetical purposes the presence of alcohol is for the most part not injurious, and

the mixture of malonic ether and alcoholic $NaOEt$ may be used at once. This reacts upon organic halogen compounds thus:—

$CHNa(CO_2Et)_2 + XI \rightarrow CHX(CO_2Et)_2 + NaI$, the reaction being energetic at first but often requiring heat to finish it. If the substances are mixed in the right proportion the end of the reaction is recognised by the solution becoming neutral. Water is then added, and if X is a hydrocarbon radicle, $CHX(CO_2Et)_2$ separates as an oil, which may be purified by fractional distillation. The resulting $CHX(CO_2Et)_2$ still contains hydrogen displaceable by sodium, and if it be mixed with alcoholic $NaOEt$ and another halogen compound, say YI , the reaction

$CNaX(CO_2Et)_2 + YI \rightarrow NaI + CXY(CO_2Et)_2$, takes place (Conrad a. Bischoff, A. 204, 121). When the substituted malonic ethers are saponified acids are obtained, which at 150° or 160° give off CO_2 and leave derivatives of acetic acid: $CHX(CO_2H)_2 = CO_2 + CH_2X.CO.H$
 $CXY(CO_2H)_2 = CO_2 + CHXY.CO.H$.

Hence malonic ether may be used, like acetoacetic ether, to effect the synthesis of organic acids of the general formula $CXYH.CO_2H$ where X and Y may be alkyls, groups like $CH_2.CO_2Et$, or other radicles. When it is desired to prepare a di-alkyl-malonic ether it is not necessary to perform the operation in two stages, for the proper quantity of $NaOEt$ (2 mols.) may be added all at once, and then the alkyl iodide (2 mols.). By the action of $AcCl$ on sodio-malonic ether in ethereal solution it may be converted into acetyl-malonic ether (120° at 17 mm.), which is soluble in $KOHAq$; the yield is 55 p.c. of its weight. This ether forms an oxim and a phenyl-hydrazide, and therefore appears to be $CH_3.CO.CH(CO_2Et)_2$. When sodio-aceto-acetic ether is acted upon by chloroformic ether $ClCO_2Et$ the same ketonic ether $CH_3.CO.CH(CO_2Et)_2$ should be formed; but the product is found to be insol. conc. $KOHAq$, and to boil at a higher temperature (127° at 17 mm.). It is decomposed by cold dilute KOH , and gives CO_2 and alcohol. The latter compound would therefore appear to be $CH_3.C(OCO_2Et):CH.CO_2Et$ (Michael, Ann. 10, 158; J. pr. [2] 37, 473; cf. Lange, B. 20, 1325).

Reactions.—1. EtI gives ethyl-malonic ether.

2. Benzyl chloride gives mono- and di-benzyl-malonic ether and regenerated malonic ether (Bischoff a. Siebert, A. 239, 94).—3. Malonic ether (32 g.), sodium (9.2 g.), dry alcohol (200 g.) and chloroform (12 g.) react thus (Conrad a. Guthzeit, A. 222, 250). $2CNa(CO_2Et)_2 + CHCl_3 = 3NaCl + CNa(CO_2Et)_2.CH:C(CO_2Et)_2$, forming sodium di-carboxy-glutaconic ether (q. v.).—4. Trimethylene bromide reacts with formation of

$(CO_2Et)_2C < \begin{smallmatrix} CH_2 \\ CH \end{smallmatrix} > CH_2$ (Perkin, jun., C. J. 51,

1, 702, 820).—5. $NaOEt$, allyl iodide, and isobutyl iodide gives an acid C_4H_9O , instead of allyl-isobutyl-malonic acid.—6. Chloro-formic ether $ClCO_2Et$ forms methane tricarboxylic ether $CH(CO_2Et)_3$ (Conrad a. Bischoff, A. 214, 81; Claisen, B. 21, 3567).—7. Tri-bromo-di-nitro-benzene dissolved in ether reacts with formation of $C_6H_2Br(NO_2)_2.CH(CO_2Et)_2$ [75°], although bromobenzene does not react (Jackson a. Robinson, B. 21, 2034).—8. Phthalyl chloride (1 mol.) added to sodium-malonic ether (2 mols.) dissolved in ether forms phthalyl-malonic ether C_6H_4O ,

[75°], phthalyl-dimalonic ether $C_{20}H_{20}O_{10}$ [48-5°], and 'phthaloxyl-dimalonic' ether $C_{20}H_{20}O_{10}$ [116-5°] (Wislicenus, *A.* 242, 23).—9. Treatment with the *chloride of mono-ethyl phthalate* $CO_2Et.C_6H_4.COCl$ dissolved in benzene forms $(CO_2Et.C_6H_4.CO)_2C(CO_2Et)_2$ [above 180°] (Zelinsky, *B.* 20, 1012).—10. In alcoholic solution it is probably converted by carbonic acid gas into $(CO_2Et)_2CH.CO_2Na$ (Michael, *J. pr.* [2] 35, 453).—11. Carbon disulphide added to an alcoholic solution of sodium-malonic ether gives yellow plates of $(CO_2Et)_2CNa.CS.Na$.—12. SO_3 acts according to the equation $SO_3 + CHNa(CO_2Et)_2 + HOEt = CH_2(CO_2Et)_2 + NaO.SO.OEt$.—13. Resorcin dissolved in alcoholic sodium malonic ether gives a greenish-blue fluorescence, when after a few days the liquid is poured into water and acidified, a small pp. of needles of a condensation product $C_{12}H_8O_8$ [191°] is got. A little above its melting-point it is split up into CO_2 and (β)-methyl-umbelliferone of which it is probably the carboxylic acid (Michael, *J. pr.* [2] 37, 469).—14. Sulphur dissolves in alcoholic sodium-malonic ether, and at 100° crystals separate. From these, acids liberate a stinking oil (thiotartronic ether?).—15. With alcohol and cinnamic ether at 100° it forms $C_{18}H_{22}O_8$ (305°-310°). It is probably $Ph.CH(CHNa.CO_2Et).CH(CO_2Et).CO_2Et$, for on saponifying and heating the resulting acid, phenyl-glutaric acid $CO_2H.CH_2.CH_2.CH_2.CO_2H$ is got (Michael, *J. pr.* [2] 35, 519).—16. Phenyl cyanate $PhNCO$ acts violently upon an alcoholic solution of sodium-malonic ether with formation of $(CO_2Et)_2CH.CONHPh$ [124°] and the salt of an acid $C_{12}H_9NO_5$ [172°] (Michael, *J. pr.* [2] 35, 452).—17. Phenyl thio-carbinol forms crystalline $C_{12}H_{11}NaSNO_5$, whence acids separate $NHPh.CS.CH(CO_2Et)_2$ [60°] (Michael, *Ann.* 9, 124).—18. Urea dissolves in malonic ether and rhombic prisms of $CHNa < \begin{smallmatrix} CO-NH \\ CO-NH \end{smallmatrix} > CO$ separate, whence acids liberate barbituric acid (Michael, *J. pr.* [2] 35, 456).—19. Thio-urea gives similarly flat plates of sodium thio-barbiturate $CHNa < \begin{smallmatrix} CO-NH \\ CO-NH \end{smallmatrix} > CS$, whence acids liberate thiobarbituric acid, which crystallises in six-sided plates from water.—20. Acetamide forms crystalline $C_{10}O_4N_4Na_4H_8$, the reaction which occurs being $2CHNa(CO_2Et)_2 + 2CH_3.CO.NH_2 = C_{10}O_4N_4Na_4H_8 + CH_2(CO_2Et)_2 + 2HOEt$.—21. $CSCl_2$ forms $CS.C(CO_2Et)_2$, which crystallises in flesh-coloured needles [178°] (Bergreen, *B.* 21, 337). 22. Iodine forms $(CO_2Et)_2CH:CH(CO_2Et)_2$. 23. Di-bromo-maleic ether yields 'di-malonylmaleic' ether [75°], whence by saponification the corresponding acid $C_8H_4O_8$ [148°] may be obtained. This acid, the formula of which is $(CO_2H)_2CH.C(CO_2H):C(CO_2H).CH(CO_2H)_2$, may be better called butylene hexa carboxylic acid. It crystallises in plates, v. sol. water, and forms the salts, Na_2A' 10aq and Ag_2A' , and the ethers Me_2A' [129°] and Et_2A' [75°] (Pum, *M.* 9, 460). When the acid is heated it splits up into CO_2 and butylene tetracarboxylic acid $CO_2H.CH_2.C(CO_2H):C(CO_2H).CH_2.CO_2H$. [176°]. 24. Dry cyanogen chloride forms cyano-malonic ether (Haller, *A. Ch.* [6] 16, 419).

Di-sodium-malonic ether

$ONa_2(CO_2Et)_2$. Obtained by ppg. malonic ether (1 mol.) with $NaOEt$ (2 mols.) (Bischoff a. Raab,

B. 17, 2782). Very unstable. Iodine converts it into $(CO_2Et)_2C:C(CO_2Et)_2$.

Ethyl propyl ether EtPrA'. [211°]. S.G. § 1-0498. S.V. 207-8 (Wiens, *A'* 253, 297).

Propyl ether PrA'. [228°]. S.G. § 1-0371. S.V. 234-6 (Wiens, *A.* 253, 297). S.H. (from 11-6° to 82-3°) 453 (R. Schiff, *G.* 17, 286).

Butyl ether (C₄H₉)₂A'. [251-5°]. S.G. § 1-0049. S.V. 269-1 (Wiens, *A.* 253, 297).

Chloride $CH_2(COCl)_2$. (58° at 27 mm.). From malonic acid and $CSCl_2$ heated above 100° (Béhal a. Auger, *Bl.* [2] 50, 594). Liquid. Smells slightly like chloral.

Amide $CH_2(CONH_2)_2$. [170°] (Van't Hoff, *Ar. Nécl.* 10, 274). S. 8-3 at 8° (Henry, *Bl.* [2] 43, 618). From malonic ether (50 c.c.) by shaking with strong aqueous NH_3 (150 c.c.) (Osterland, *B.* 7, 1286; Freund, *B.* 17, 133). The yield, in 2 days, is 75 p.c. Silky needles (from dilute alcohol), insol. alcohol and ether. Boiling aqueous NH_3 converts it into ammonium malonamate. Salt.— $CH_2 < \begin{smallmatrix} CO.NH \\ CO.NH \end{smallmatrix} > Hg$: white

amorphous powder, insol. alcohol and ether, sl. sol. hot water, v. sol. $HClAq$ (Freund).

Di-methyl-amide $CH_2(CO.NHMe)_2$. [128°] (F.); [125°] (Henry); [136°] (Franchimont, *It. T. C.* 4, 199). Formed by the action of methylamine on malonic ether (Freund, *B.* 17, 133). Small flat needles. V. e. sol. water and alcohol, sl. sol. ether. Fuming HNO_3 converts it into $CH_2(CO.N(NO_2)Me)_2$ [150°].

Di-ethyl-amide $CH_2(CO.NHEt)_2$. [149°]. Six-sided tables (Wallach a. Kamenski, *B.* 14, 170).

Ethylene diamide $CH_2 < \begin{smallmatrix} CO.NH \\ CO.NH \end{smallmatrix} > C_2H_4$.

Formed by heating malonic ether or malonamide with ethylene-diamine (Freund, *B.* 17, 137). Crystalline solid. V. sol. water, nearly insol. alcohol.

Amide-anilide $CONH_2.CH_2.CONHPh$. [163°]. Obtained by heating malonamide with 1 mol. of aniline for ½ hour at 200°-220° (Freund, *B.* 17, 135). Fine white felted needles. Sol. hot water and alcohol.

Mono-anilide $CO_2H.CH_2.CO.NHPh$. *Phenyl-malonamic acid*. *Malonanilic acid*.

Malonphenylamic acid. [132°]. Formed by boiling the amide-anilide with milk of lime (Freund, *B.* 17, 135). Formed also by heating sodiumacetyl-phenyl-carbamate $C_6H_5Nac.CO_2Na$ for 5 or 6 hours at 130°-140° under pressure (Seifert, *B.* 18, 1359), and by heating malonic acid (1 mol.) with aniline (1 mol.) at 105° (Rügheimer, *B.* 17, 737). Large colourless monoclinic crystals, slender needles. At its melting-point it breaks up quantitatively into CO_2 and acetanilide.— $A'Ag$: small white needles.— A'_2Ca 4½aq: large needles.

Ethyl ether of the mono-anilide $CO_2Et.CH_2.CONHPh$. [39°]. From aniline and $CO_2Et.CH_2.COCl$, both dissolved in benzene (Rügheimer a. Hoffmann, *B.* 17, 739). Crystals (from ether-ligroin). Insol. water and ligroin, v. e. sol. alcohol and benzene.

Anilide $CH_2(CONHPh)_2$. [223°]. Obtained by boiling malonic ether or malonamide with aniline (Freund, *B.* 17, 134). White needles. Insol. water and ether, s. sol. hot alcohol.

Benzoyl derivative
 $C_6H_5.CH(OH).C(NH_2)NOBz.$ [149°]. From
 mandelamidoxim and $BzCl$ (1 mol.). With

AsCl it gives $C_6H_5.CH(OAc).C(NH_2).NOBz$ [165°] (Gross).

MANDELIC ACID $C_6H_5.CO_2H$, i.e. $C_6H_5.CH(OH).CO_2H$. *Phenyl-glycollic acid*. *Oxy-phenyl-acetic acid*. Mol. w. 152. [115°] (Müller, *Ar. Ph.* [8] 2, 385); [118°] (Claisen, *B.* 10, 847; Lewkowitz, *B.* 16, 1568). S.G. 1.361 (Schröder, *B.* 12, 1612). S. 16 at 20°. *Heat of solution*: -3100. *Heat of neutralisation* by NaOH: +13860 (Berthelot, *A. Ch.* [6] 7, 185).

Formation.—1. Discovered by Winckler (*A.* 18, 810), who obtained it by heating bitter almond water with HCl, the benzoic aldehyde reacting with the HCl present (Liebig, *A.* 18, 819).—2. By heating amygdalin with fuming HClAq (Wöhler, *A.* 66, 238).—3. By boiling the compound of benzoic aldehyde with $KHSO_5$ for several hours with KCy and alcohol. The nitrile $C_6H_5.CH(OH).CN$ thus formed is saponified by dilute HClAq (O. Müller, *B.* 4, 980).—4. By reducing phenyl-glyoxylic acid $C_6H_5.CO.CO_2H$ with sodium-amalgam (Schwobel, *B.* 10, 2045).—5. From di-bromo-acetophenone $C_6H_4.CO.CHBr_2$ by boiling with dilute KOHAq (1:20), the compound $C_6H_5.CO.CH(OH)$, being a theoretical intermediate product (Engler, *A.* Wöhler, *B.* 20, 2202).—6. In small quantity, by boiling pseudo-phenyl-hydantoin with baryta (Pinner, *B.* 21, 2327).—7. By boiling α -chloro-phenyl-acetic acid with alkalis (Spiegel, *B.* 14, 239).

Preparation.—Benzoic aldehyde (100 g.), water (3500 c.c.), fuming HClAq (200 g.), and 4 times the calculated quantity of hydrogen cyanide are boiled for 36 hours. The product is evaporated at 100°, the residue extracted with ether, the extract evaporated, and the mandelic acid left recrystallised from water (Wallach, *A.* 193, 88; cf. Strecker, *A.* 75, 27).

Properties.—Large trimetric crystals; v. sol. water, alcohol, and ether. Inactive to light. By crystallisation of the cinchonine salt it can be separated into equal quantities of the dextro- and levorotatory acids. If *Penicillium glaucum* is grown in it the levorotatory acid is destroyed, leaving the dextrorotatory (Lewkowitz, *B.* 16, 1568).

Reactions.—1. $KMnO_4$ and KOH convert it, in the cold, into phenyl-glyoxylic acid (R. Meyer, *A.* A. Baur, *A.* 220, 39).—2. Dry distillation yields benzoic aldehyde.—3. Boiling with MnO_2 and H_2SO_4 yields benzoic aldehyde and CO_2 .—4. Fuming $HBrAq$ converts it slowly in the cold, quickly at 125°, into α -bromo-phenyl-acetic acid, whence alcoholic NaOEt forms the ethyl derivative of mandelic acid (Glaser, *A.* Radziszowsky, *Z.* [2] 4, 140).—5. Fuming HClAq at 140° gives α -chloro-phenyl-acetic acid.—6. Phosphorus and HI reduce it to phenyl-acetic acid.—7. When taken internally it passes unaltered into the urine (Schotten, *H.* 8, 68).—8. Cannot be nitrated. Conc. HNO_3 forms benzoic aldehyde (Liebig, *A.* 18, 321), dilute HNO_3 forms phenyl-glyoxylic acid (Zincke, *A.* Hannäus, *B.* 10, 1489).—9. Dilute H_2SO_4 in sealed tubes at 180° converts* mandelic acid nearly quantitatively into benzoic aldehyde and formic acid (Biedermann, *B.* 19, 638).—10. Chloral at 120° forms

which forms large transparent crystals (83°); insol. water, sol. alcohol and chloroform (Wal-

lach, *A.* 193, 1).—11. *Phenyl-hydrasine* forms a compound [182°], crystallising in needles and almost insol. boiling water (Reissert, *A.* Kayser, *B.* 22, 2928).

Salts.—The ammonium and potassium salts are very soluble and difficult to crystallise. The Ba salt forms small needles. S. 8 at 24°; 16 at 100° (Zinin, *Z.* 1868, 710). The lead salt is a crystalline powder, scarcely sol. water.— CuA' , (dried at 100°).— AgA' , crystalline pp. May be crystallised from water.

Methylether MeA'. [48°]. Small laminae (from benzene-ligroin) (Zincke, *A.* Breuer, *B.* 13, 636).

Ethyl ether $Ph.CH(OH).CO_2Et$. (254°). Formed by the action of water on the hydrochloride of mandelic imido-ether (*q.v.*). Solidifies in a freezing mixture, but is liquid at ordinary temperatures (Beyer, *J. pr.* [2] 31, 889). But Naquet and Luguinin (*A.* 139, 800), who prepared it from silver mandelate and EtI, say it melts at 75°.

Methyl derivative $Ph.CH(OMe).CO_2H$. [72°]. Formed from $Ph.CHCl.CO_2Me$, $MeOH$, and NaOMe (R. Meyer, *A.* H. Boner, *A.* 220, 44; *B.* 14, 2392). Needles grouped concentrically (on solidifying) or thick tables (from light petroleum). V. sol. alcohol or ether, sl. sol. cold water or cold petroleum. $\ll OH$ and $KMnO_4$ forms phenyl-glyoxylic acid.

Salts.— NaA' , 2aq.— BaA' , 2aq.— CaA' ,— CuA' , 2aq.— AgA' .

Methylether of the methyl derivative $Ph.CH(OMe).CO_2Me$. (246° cor.).

Ethyl derivative $C_6H_5.CH(OEt).CO_2H$. From $C_6H_5.CHBr.CO_2H$ and alcoholic KOEt. Viscid mass.— AgA' : pulverulent pp.

Phenyl derivative $Ph.CH(OPh).CO_2H$. [108°]. From methyl α -chloro-phenyl-acetate and sodium phenate (R. Meyer, *A.* H. Boner, *A.* 220, 51). Radiating groups of slender needles (from water). V. sl. sol. cold water, v. s. sol. alcohol or ether. KOH and $KMnO_4$ convert it into phenyl-glyoxylic acid. HNO_3 forms picric acid and benzoic aldehyde.— NaA' , 3aq.— CuA' ,— AgA' .

Acetyl derivative of the ethyl ether $C_6H_5.CH(OAc).CO_2Et$. [74°]. From mandelic acid by successive treatment with AcCl and alcohol (Naquet, *A.* Luguinin, *A.* 130, 302). Slender needles (from ether). Insol. water, v. sol. alcohol and ether.

Amide $C_6H_5.CH(OH).CONH_2$. [132°]. S. 3 at 21°. S. (boiling 93 p.c. alcohol) 100 (Z.). Formed, together with benzoic aldehyde, by heating the compound $(C_6H_5.CHO).CNH$ with water or alcohol at 180° (Zinin, *Z.* [2] 4, 709). Formed also by allowing a mixture of the nitrile with fuming HClAq to stand in the cold (Tiemann, *A.* Friedländer, *B.* 14, 1967). Likewise obtained by the action of NH_3 on mandelic ether, and by heating mandelic imido-ether (C. Beyer, *J. pr.* [2] 31, 896). Prismatic needles or plates. Sol. hot, sl. sol. cold, water; sl. sol. ether, v. sol. alcohol. Decomposed by acids and alkalis with production of mandelic acid. A polymeride (?) melts at 190°.

Nitrile $C_6H_5.CH(OH).CN$. [-10°]. S.G. 1.124. Obtained by adding fuming HClAq to a mixture of benzoic aldehyde and KCy (Spiegel, *B.* 14, 239; Völkel, *A.* 52, 361). Oil; sol. alco-

hol and ether. Dissolved in ether, mixed with alcohol (1 equivalent), and treated with HCl gas it forms $C_6H_5.CH(OH).C(OEt).NH_2.HCl$ [125°]. This is decomposed by water, forming NH_4Cl and mandelic ether (Beyer, *J. pr.* [2] 28, 190). At 170° mandelonitrile splits up into benzoic aldehyde and HCl. Boiling aqueous HCl gives NH_4Cl and mandelic acid. Fuming $HClAq$ forms the amide in the cold, but on heating it gives α -chloro-phenyl-acetic acid. NH_3 in the cold forms $C_6H_5.CH(NH_2).CN$. Methylamine yields $C_6H_5.CH(NHMe).CN$. Phenyl-hydrazine produces the phenyl-hydrazone of benzoic aldehyde (Reissert, *B.* 17, 1451).

(*dextro*)-Mandelic acid [133° cor.]. $[\alpha]_D$ at 20° = +156. Prepared by converting inactive mandelic acid into the cinchonine salt and adding a crystal of cinchonine *dextro*-mandelate to the aqueous solution when the *dextro*-salt crystallises out, leaving the *lavo*-salt in solution. It can be also obtained by growing *Penicillium glaucum* in the inactive acid, which destroys the levorotatory acid, leaving the *dextro*rotatory (Lewkowitsch, *B.* 16, 1568). Resembles the *lavo*-acid, having the same solubility in water.

(*lavo*)-Mandelic acid [133°]. $S. 8.64$ at 20° $[\alpha]_D$ at 20° = -158. Prepared by heating amygdalin with strong HCl for several hours on the water-bath. It can also be obtained from inactive mandelic acid, which can be separated into equal quantities of the *lavo*- and *dextro*-rotatory acids by crystallisation of the cinchonine salt (Lewkowitsch, *B.* 16, 1565; cf. Wöhler, *A.* 66, 240).

Nitro-mandelic acid v. NITRO-OXY-PHENYL-ACETIC ACID.

MANDELIC IMIDO-ETHER

$Ph.CH(OH).C(NH).OEt$. [72°].

Preparation.—Benzoic aldehyde (100 g.) treated with KCN, dilute HCl and ether forms the cyanhydrin $Ph.CH(OH).CN$ which is dissolved by the ether. If this is mixed with an equivalent of alcohol and dry HCl be passed in, the liquid being cooled, needles of the hydrochloride of mandelic imido-ether (80g.) are formed (C. Beyer, *J. pr.* [2] 81, 384). $Ph.CH(OH).CN + EtOH + HCl = PhCH(OH).C(NH).OEt.HCl$. These melt at [125°]. The free ether is got by shaking these simultaneously with conc. KOH and ether. After evaporating the ether the residue is crystallised from ligroin.

Properties.—White needles. Extremely soluble in ether, alcohol, and benzene.

Reactions.—1. At 140° the hydrochloride splits up thus: $PhCH(OH).C(NH).OEt.HCl = EtCl + PhCH(OH).CONH_2$, forming mandelamide. 2. Alcoholic NH_3 converts the hydrochloride into the hydrochloride of α -amidine, $Ph.CH(OH).C(NH)NH_2.HCl$. This forms prisms [214°]. Shaken with ether and potash, the free mandelamide, $Ph.CH(OH).C(NH)NH_2$, is dissolved by the ether. It forms feathery needles of narcotic odour, melting at [110°].—3. Water quickly converts the hydrochloride into mandelic ether (q. v.) $C_6H_5.CH(OH).C(NH).OEt.HCl + H_2O = C_6H_5.CH(OH).CO.OEt + NH_4.HCl$.

MANDRAGORINE $C_{17}H_{25}NO_4$. [c. 79°]. Extracted from powdered mandragora root by alcohol. The extract is evaporated and the residue treated with very dilute acid. The alkaloid is liberated from the acid solution by $Vol. III.$

adding K_2CO_3 and shaking with ether (Ahrens, *A.* 251, 812). Hygroscopic brittle mass. Picric acid gives with a solution of mandragorine hydrochloride light-yellow needles of the picrate. Iodine in $KIAq$ gives an oily periodide. K_2FeO_4 gives no pp. Phosphotungstate gives a white pp. The sulphate is crystalline and very geliquescent. Dropped into the eye, its solution causes enlargement of the pupil.— B^+HAuCl_4 : [155°]; yellow plates; sol. hot water and $HClAq$.— $B^+H_2P_2Cl_6$: [194°]. Red nodules or yellow plates (from hot water).— $B^+HCl_4HgCl_2$: [160°]. Plates or needles (from water) or long slender needles (from alcohol). V. sol. alcohol (Ahrens, *B.* 22, 2161).

Mandragora root also contains a second alkaloid of which the platinochloride [181°] and aurochloride [147°–153°] are crystalline (Ahrens).

MANGANATES. Salts of the form $M^+MnO_4^-$, derived from the hypothetical acid H_2MnO_4 ; v. MANGANESE, OXYACIDS OR, p. 186.

MANGANESE. Mn. At. w. 55. Mol. w. probably same as At. w. (v. *infra*). [c. 1800°–1900°]. S.G. 6.85 to 8.01; according to Glatzel, S.G. of pure Mn is 7.3921 at 22° (*B.* 22, 2857). S.H. 14° to 97° 1217 (Regnault, *A. Ch.* [3] 67, 427; specimen contained Si). Chief lines in emission-spectrum are 6521, 6016, 6018, 4823, 4783, 4765, 4762, 4753, 4235, 4027 (Thalén). For absorption-spectrum of Mn vapour v. Lockyer & Roberts (*Pr.* 23, 344).

Occurrence.—The metal does not occur uncombined. Mn compounds are widely distributed; the chief are *pyrolusite* MnO_2 , *braunite* Mn_2O_3 , *manganite* $Mn_2O_3.H_2O$, *hausmannite* Mn_3O_4 , *psilomelane* $(Mn,Ba,K)_2O.4MnO_3$, *manganese-spar* $MnCO_3$, *manganese-blende* MnS . Small quantities of Mn compounds are found in sea-water (Forchhammer, *Pr.E.* 2, 803); in many mineral waters (Buchanan, *Pr.* 24, 593); in blood (Cottureau, *J.* 1849. 530; Burin de Buisson, *J.* 1852. 377; Campani, *B.* 5, 287); in the liver (Béchamp, *C. R.* 49, 895); in milk (Pelacoi, *Naturforscher*, 4, 122); in human urine (Horsford, *J.* 1851. 602); in wines, cereals, most vegetables used as human food, and in considerable quantities in tea (Maumené, *C. R.* 98, 1056, 1416). Mn also occurs in the sun's atmosphere (Cornu, *C. R.* 86, 315, 530).

Manganese dioxide was recognised as a compound of a distinctive metal by Scheele in 1774; it had previously been looked on as a compound of iron. The metal Mn was first isolated by Gahn. Native MnO_2 was long known as *magnesia nigra* (probably because of its supposed magnetic properties); a new medicine was introduced in the early years of the eighteenth century, and was called *magnesia alba*, seemingly in contradistinction to *magnesia nigra*; when *magnesia nigra* was shown to contain a distinctive metal, this metal was called sometimes *maguestum* and sometimes *manganesium*; finally the name *maguestum* was retained for the metal of *magnesia alba*, and the name *manganesium* (hence *manganese*) was given to the metal of *magnesia nigra*.

Formation.—1. By reducing the oxides by C at a white heat.—2. By reducing MnF_2 or $MnCl_2$ by Na or by Mg.—3. By heating Mn amalgam in a stream of H; the amalgam is made by the reaction of Na amalgam with $MnCl_2Aq$ (Giles, *N.*

P. M. [4] 24, 328; Roussin, *Bl.* 6, 93).—4. By electrolysis MnCl_2 in a porous cell placed in a carbon crucible containing HClAq (Bunsen, *P.* 91, 619).

Preparation.—1. Crystallised MnCl_2 is thoroughly dried by heating; it is then finely powdered and 100 grams are intimately mixed with 200 grams well dried and powdered KCl ; the mixture is packed into a Hessian crucible which is loosely covered and heated in an air-furnace until the contents melt (the temperature must not be raised so high that white vapours begin to come off); the lid is removed and 15 grams Mg are thrown into the crucible in four or five portions, each weighing 3 to 4 grams, two to three minutes being allowed to elapse between the entrance of each piece; the lid is now replaced and the crucible is strongly heated for a few minutes, and then allowed to cool very slowly in the furnace. About 20 to 25 grams Mn are thus obtained as a compact regulus. If the temperature of the final heating is not sufficiently high, the regulus does not form a compact mass; if the temperature is too high and the heating is unduly prolonged, the KCl is vaporised and the surface of the Mn is oxidised (Glatzel, *B.* 22, 2357).—2. Brunner (*P.* 101, 264) recommends the following method:—2 pts. MnF_2 (obtained by dissolving moist MnCO_3 in HFAq , evaporating and drying at 100°) and 1 pt. Na are arranged in alternate thin layers in a Hessian crucible, the mixture is pressed down and covered with NaCl over which is placed a layer of CaF_2 in small pieces (to prevent spitting); the crucible is covered and heated in an air-furnace, at first gently, and then to near a white heat for about $\frac{1}{2}$ an hour; the crucible is then allowed to cool very slowly in the furnace.—3. For an account of the older methods of preparing Mn from MnO_2 , v. John (Gehlen's *Journ. Chem. Phys.* 3, 452), and Deville (*A. Ch.* [3] 46, 182). Tamm describes a method for obtaining approximately pure metal (99.91 p.c. Mn , .05 p.c. Fe , .115 p.c. Si , and .025 p.c. O) from MnO_2 (*C. N.* 26, 73, 111).

Properties.—A white-grey, lustrous, metal; very hard; brittle; may be highly polished; non-magnetic (Glatzel). According to Glatzel (*B.* 22, 2357), Mn prepared by reducing MnCl_2 by Mg (*v. Preparation* No. 1) is unchanged by keeping for months in a bottle closed with a glass stopper; but in moist air the surface undergoes slight oxidation. Mn is usually described as very easily oxidised in ordinary air, and as capable of decomposing water, with evolution of H_2 , almost as rapidly as K . Mn obtained by Brunner (*v. Preparation* No. 2) by reducing MnF_2 by Na was scarcely oxidised in cold water. According to Bullock (*C. N.* 60, 20), Mn prepared by reducing the oxides by C is very easily oxidised, while specimens obtained by reducing MnCl_2 by Na are no more oxidisable than iron. It is probable that some specimens have contained small traces of Si and C which have affected the properties of the metal. Mn melts at a very high temperature (c. 1800° – 1900°), and is said to volatilise at a full white heat.

The atomic weight of Mn has been determined (1) by estimating Cl in MnCl_2 (Arfvedson, *S.* 42, 202; Dumas, *A. Ch.* [3] 55, 151; Berzelius, *P.* 18, 74); (2) by dissolving Mn in HNO_3 ,

evaporating, and calcining the nitrate (Berzelius, *P.* 8, 185); (3) by oxidising MnO to Mn_2O_3 by heating in air (*v. Hauer*, *W. A. B.* 25, 138); (4) by reducing Mn_2O_3 in H_2 and weighing H_2O produced (Rawack, *P.* 107, 665, 616); (5) by analysing MnC_2O_4 (Schneider, *P.* 107, 605); (6) by reducing AgMnO_2 and estimating Ag produced (Dewar & Scott, *Pr.* 35, 44); (7) by determining S.H. (Regnault, *A. Ch.* [3] 67, 427).

Molecular weight of manganese.—Ramsay (*C. J.* 55, 521) has determined the lowering of the vapour pressure of Hg produced by dissolving Mn in Hg ; the results render it probable that the molecular weight of Mn is the same as the atomic weight. This conclusion assumes the accuracy of Van't Hoff's law that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved substances, and it also supposes the molecular weight of liquid Hg to be the same as the atomic weight of Hg .

Mn is metallic in its physical, and some of its chemical, properties; but in many of its reactions it behaves as a non-metal. The oxides MnO and Mn_2O_3 are basic, forming salts, such as MnSO_4 and $\text{Mn}_2(\text{SO}_4)_3$, of which the manganous salts, corresponding with MnO , are much the more stable. The oxide MnO_2 reacts as a basic peroxide, e.g. with H_2SO_4 , it forms MnSO_4 and O ; it also reacts with some positive oxides, e.g. CaO , to produce salts of the form $x\text{MO} \cdot y\text{MnO}_2$; when this oxide is treated with molten KOH in presence of O the salt K_2MnO_4 is formed, in which Mn forms part of the acidic radicle. The oxides MnO and Mn_2O_3 have also been isolated; both are very unstable; both react with water to form manganic acid HMnO_3 , the former (MnO_2) at the same time also producing MnO_2 ; these oxides are distinctly acidic. The acid HMnO_3 has been isolated, and many salts derived from the hypothetical acid H_2MnO_4 are known.

Mn shows marked analogies with the iron metals Fe , Ni , and Co ; it is also related, although less distinctly, to the halogens; and it is also related to the chromium metals, Cr , Mo , W , and U . In the classification of the elements based on the periodic law, Mn occupies a position different from that of any known element: it is placed in the same group as the halogens (Group VII.), and in the same family (even-series members) as F , but no member of this family coming after Mn (i.e. with a greater atomic weight than Mn) has yet been isolated; Mn finds a place in series 4 (K , Ca , Sc , Ti , V , Cr , Mn), all the members of which are metallic, and it is immediately followed by Fe , Ni , Co , and Cu . The strongly marked negative character of the halogens is impressed on Mn , but this is counterbalanced by the positive characteristics of the metals which come before and after Mn in order of atomic weights (*v. HALOGEN ELEMENTS*, vol. ii. p. 666; also *IRON GROUP OF ELEMENTS*, this vol. p. 65).

The atom of Mn is divalent in the gaseous molecule MnCl_2 .

Reactions.—1. Mn is oxidised in air or oxygen, forming MnO .—2. Mn reacts energetically with dilute mineral acids forming salts of MnO . 3. Fused with potassium nitrate or chlorate KMnO_4 is produced.—4. Heated in bromine MnBr_2 is formed.—5. When Mn is heated in a stream

of hydrogen chloride MnCl_2 is produced.—*v. mn* decomposes water readily, with evolution of H_2 . The reactions of the metal have not been much examined.

Combinations.—Mn forms alloys with many metals, and compounds with most of the non-metals, but few have been formed by the direct union of their elements.

Detection and estimation.—Mn is usually detected by the colour its compounds impart to a borax-bead, and by the ppn. of buff-coloured MnS by addition of NH_4 sulphide to an alkaline or neutral solution of Mn salts. Mn is usually estimated gravimetrically by ppn. with NH_4Aq , heating the pp. in air, and weighing as Mn_2O_3 . As MnO_2 is much used in technical chemistry it is necessary to have accurate and rapid methods for determining the quantity of this oxide in specimens of Mn ores; for descriptions of these methods, and also for other methods for estimating Mn, reference must be made to *Manuals of Analysis*.

Manganese, alloys of. Several alloys of Mn have been prepared; none has been made by directly alloying Mn with other metals.

1. With *aluminium*. Wöhler & Michel (*A.* 115, 102) obtained a crystalline powder, having the composition MnAl_3 , by fusing together MnCl_2 , Al, and a mixture of NaCl and KCl.

2. With *copper*. Alloys of Mn and Cu are obtained by reducing mixtures of MnO_2 and Cu with charcoal; an alloy containing 25 p.c. Mn is white, fairly hard, very elastic, and tolerably easily melted (Allen, *C. N.* 22, 184). Alloys containing from 8 to 20 p.c. Mn resemble bronze (Valenciennes, *C. R.* 70, 607; *v. also* Schröter, *D. P. J.* 210, 865; Prieger, *ibid.* 177, 303; Gintl, *ibid.* 224, 653).

3. With *iron*. Alloys of Mn and Fe, containing from 8 to 80 p.c. Mn, are used in the manufacture of steel, under the names of *spiegeleisen* and *ferromanganese*. These alloys are prepared by heating MnO_2 with iron filings and charcoal in the blast-furnace, or in graphite crucibles, or by reducing a mixture of FeO and MnCO_3 on the hearth of a Siemens' furnace, and then fusing under a reducing flame.

4. With *mercury*. An amalgam of Mn is obtained by reducing MnCl_2Aq by Na-amalgam (Giles, *P. M.* [4] 24, 328); also by electrolyzing MnCl_2Aq in contact with Hg (Ramsay, *C. J.* 55, 582; Moissan, *Bl.* [2] 31, 149). Alloys of Mn with Pb, Sn, and Zn are described by Allen (*loc.*) and Valenciennes (*loc.*).

Manganese, arsenates of; v. vol. i. p. 309.

Manganese, arsenide of. Mn and As combine when heated together to redness. An arsenide, approximately As_3Mn_2 , occurs native (Kane, *P.* 19, 145).

Manganese, arsenite of; v. vol. i. p. 306.

Manganese, boride of. By heating Mn_2O_3 (*v. Manganese, carbides of*) with B_2O_3 in a graphite crucible, Troost and Hautefeuille obtained small greyish-violet crystals of MnB_2 (*C. R.* 81, 1283). This compound decomposes water at 100° and dissolves in acids with evolution of H_2 ; it reacts with moist HgCl_2 to produce MnCl_2 , boric acid, and HCl .

Manganese, bromides of. Only one bromide, MnBr_2 , has been isolated; the tetrabromide also perhaps exists in solution.

MANGANESE BROMIDE, MnBr_2 . *Manganese dibromide.* The hydrate $\text{MnBr}_2 \cdot 4\text{H}_2\text{O}$ is obtained as clear, red, deliquescent, crystals, by dissolving MnCO_3 in HBrAq , or by digesting Mn with Br (Balard, *J. pr.* 4, 178; Marignac, *Ann. M.* [5] 12, 7); crystallises in monoclinic forms, $a:b:c = 0.645:1:1.165$ (Marignac). The anhydrous salt MnBr_2 is obtained by heating powdered Mn in Br vapour; it forms a rose-red deliquescent mass; heated in air it gives Br and Mn_2O_3 . Thomsen gives the thermal data:— $[\text{Mn}, \text{Br}^2, \text{Aq}] = 106,120$ (*Th.* 3, 271).

MANGANESE BROMIDE, MnBr_4 . (*Manganese tetrabromide*). This compound perhaps exists in the green solution obtained by treating Mn_2O_3 or MnO_2 with HBr gas and dry ether; the solution is easily decomposed with formation of MnBr_2 (Nicklès, *C. R.* 60, 79).

Manganese, carbides of. According to Brown (*J. pr.* 17, 492), the compound MnC is obtained by heating $\text{Mn}(\text{SCy})_2$ and MnC_2 by heating MnCy_2 . Troost and Hautefeuille obtained graphite-like, lustrous, crystals of MnC by melting Mn in a charcoal crucible, and cooling slowly (*C. R.* 80, 960).

Manganese, chlorides of. The only chloride of Mn which has been isolated as MnCl_2 . A solution of MnO_2 or Mn_2O_3 in conc. cold HClAq very probably contains Mn_2Cl_2 , perhaps also some MnCl_4 . The existence of MnCl_4 , described by Dumas, is very doubtful.

MANGANESE CHLORIDE, MnCl_2 . Mol. w. 125.74. Rose-coloured crystals of $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ are obtained by dissolving MnCO_3 , or any oxide of Mn, in HClAq , and evaporating; by heating the dried crystals in a stream of dry HCl , the anhydrous salt, MnCl_2 , is obtained. MnCl_2 is also formed by heating Mn, MnCO_3 , or Mn_2O_3 in a stream of dry HCl . By heating very finely powdered MnO_2 with half its weight of NH_4Cl gradually to redness, MnCl_2 is formed. MnCl_2 is very deliquescent; Brandes (*P.* 22, 263) gives S. at $10^\circ = 62.16$, at $31.25^\circ = 85.72$, at $62.5^\circ = 122.22$, at $87.5^\circ = 122.22$, and at $103.25^\circ = 123.81$. S. in alcohol at $11^\circ = 50$. S.G. of $\text{MnCl}_2 = 2.473$ (Schröder), of $\text{MnCl}_2 \cdot 4\text{H}_2\text{O} = 1.913$ (Schröder), 2.015 (Boedeker). The tetrahydrated salt is isomorphous with $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$; monoclinic, $a:b:c = 1.1409:1:1.6406$ (Marignac, *Ann. M.* [5] 15). All water is removed at 100° . Thomsen gives the thermal data: $[\text{Mn}, \text{Cl}^2] = 111,990$; $[\text{MnCl}_2, \text{Aq}] = 16,010$; $[\text{MnCl}_2 \cdot 4\text{H}_2\text{O}] = 14,470$ (*Th.* 3, 270). Heated in O_2 , a crystalline oxide containing 37 p.c. MnO , is produced (Schulze, *J. pr.* [2] 21, 407). MnCl_2 melts, in absence of air, at a red heat and sublimes at higher temperature. Scott found V.D. at c. $1200^\circ\text{--}1500^\circ$ to be 132.8 (*Pr. E.* 14, 410).

MnCl_2 forms double salts with the alkali chlorides, of the composition $\text{MnCl}_2 \cdot 2\text{XCl} \cdot 3\text{H}_2\text{O}$. The best examined are those in which $\text{X} = \text{NH}_4$, Rb , and Cs ; the NH_4 salt contains one H_2O only according to Rammelsberg (*J. pr.* 65, 181; confirmed by Pickering, *C. J.* 35, 672). The double salts are obtained by mixing MnCl_2Aq or a solution of an oxide of Mn in HClAq , with the alkali chloride, and evaporating slowly (*v. Godefroy, B.* 8, 9; *v. Hauer, J. pr.* 63, 436). Another double salt $\text{MnCl}_2 \cdot 3\text{CuO} \cdot 3\text{H}_2\text{O}$, is formed by boiling MnCl_2Aq with powdered CuO , filtering, and cooling (André, *C. R.* 106, 854). The double

salt $\text{MnCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$, is described by Bunsen (P. 17, 181).

MANGANIC CHLORIDE, Mn_2Cl_7 ; and MANGANESE TETRACHLORIDE, MnCl_4 . Neither of these chlorides has been isolated. Mn_2O_3 and MnO_2 dissolve in cold conc. HClAq to form deep-brown liquids, which slowly evolve Cl and after a time contain MnCl_2 . Nicklès (A. Ch. [4] 5, 161), by passing HCl into ether in which MnO_2 was suspended, obtained a green liquid, of varying composition and very unstable; one analysis gave results approximately agreeing with the formula $\text{MnCl}_2 \cdot 12\text{C}_2\text{H}_{10}\text{O} \cdot 2\text{H}_2\text{O}$. These results are quite inconclusive of the formation of MnCl_2 (cf. Pickering, C. J. 35, 672). Fisher's experiments (C. J. 33, 409) led him to conclude that a solution of MnO_2 in cold conc. HClAq contains MnCl_2 ; but the more complete experiments of Pickering (C. J. 35, 651) make it very probable that Mn_2Cl_7 , and not MnCl_2 , is produced when either Mn_2O_3 or MnO_2 is dissolved in cold conc. HClAq . When the solutions are decomposed by adding water, the pp. varies in composition but may always be expressed as $x\text{MnO}_2 \cdot y\text{MnO}$, x varying from 16 to 36 and y being usually 5. Pickering expresses the reactions of HClAq with Mn_2O_3 and MnO_2 , and the decomposition of the solutions by H_2O , in the following equations:—
 $\text{Mn}_2\text{O}_3 + 6\text{HClAq} = \text{Mn}_2\text{Cl}_7\text{Aq} + 3\text{H}_2\text{O}$
 $2\text{MnO}_2 + 8\text{HClAq} = \text{Mn}_2\text{Cl}_7\text{Aq} + \text{Cl}_2 + 4\text{H}_2\text{O}$
 $\{x\text{Mn}_2\text{Cl}_7\text{Aq} + 2\text{H}_2\text{O} = \text{MnO}_2 + \text{MnCl}_2\text{Aq} + 4\text{HClAq}\}$
 $\{y\text{Mn}_2\text{Cl}_7\text{Aq} + 3\text{H}_2\text{O} = \text{Mn}_2\text{O}_3 + 6\text{HClAq}\}$

The average values of x and y are 4 and 1 respectively. Christensen (J. pr. [2] 35, 57) thinks that Mn_2Cl_7 is the product of the reaction of cold HClAq with MnO_2 ; he supposes that some MnCl_2 is produced at 10° . According to C., ether holding HCl in solution produces a solution of Mn_2Cl_7 when shaken with Mn_2O_3 . According to Vernon (C. S. Proc. 1890, 58), a solution of MnO_2 in conc. HClAq evolves less than half the Cl , at ordinary temperatures, required by the equations given by Pickering (*supra*); at -18° Cl is evolved very slowly, and at -26° only '35 p.c. of the available Cl comes off when air is drawn through the solution for two hours. Vernon thinks that MnCl_2 is the only higher chloride formed by dissolving MnO_2 , Mn_2O_3 , or Mn_3O_4 in cold conc. HClAq .

Franke (J. pr. [2] 36, 38) obtained *chloromanganic acid*, HMnCl_4 , by adding KMnO_4 to ether containing HCl , shaking with dry ether, and surrounding the deep-brown liquid thus produced with a freezing mixture.

MANGANESE HEPTACHLORIDE, MnCl_7 (?). Dumas (B. J. 7, 112; 8, 177) described a greenish gas, condensing at -15° to -20° to a green-brown liquid, produced by adding excess of conc. H_2SO_4 to KMnO_4 , and throwing in small pieces of fused KCl or NaCl ; he gave the formula MnCl_7 to this substance. Aschoff's analyses of the compound proved the presence of O in it, and led to the formula MnO_2Cl (J. pr. 81, 29). The exact composition of the substance is not yet settled.

Manganese, chromate of; v. vol. ii. p. 155.

Manganese, cyanides of; v. vol. ii. p. 342.

Manganese, ferri- and ferro-cyanides of; v. vol. ii. pp. 335, 339.

Manganese, fluorides of. Two fluorides of Mn have been certainly isolated, MnF_2 and

Mn_2F_7 . The existence in solution of MnF_3 is doubtful. Wöhler obtained a gas by the reaction of H_2SO_4 with a mixture of K_2MnO_4 and KF . To this gas he assigned the composition MnF_3 , but the composition of the substance cannot be regarded as settled. Nicklès asserts the existence of Mn_2F_7 .

MANGANOUS FLUORIDE, MnF_2 (Manganese difluoride). A reddish crystalline powder, obtained by dissolving MnCO_3 in excess of HFAq , and evaporating; undecomposed by heating to redness (Berzelius).

MnF_2 forms double compounds with SiF_4 , &c. (Berzelius; Stolba, C. C. 1888, 292; Margnac, J. pr. 83, 202). These compounds, better regarded as silicofluoride, titanofluoride, &c., of Mn, have the composition $\text{MnXF}_2 \cdot 6\text{H}_2\text{O}$, where $\text{X} = \text{Si}, \text{Ti}, \text{or Sn}$; they are isomorphous, crystallising in hexagonal forms, $a:c = 1:1.515$ (Marnagac, Ann. M. [3] 15). There is also a zirconofluoride of Mn, $\text{MnZnF}_2 \cdot 5\text{H}_2\text{O}$, which crystallises in monoclinic forms, $a:b:c = 2.09:1:1.2515$ (M. l. c.).

MANGANESE SESQUIFLUORIDE, Mn_2F_7 . Crystals of $\text{Mn}_2\text{F}_7 \cdot 6\text{H}_2\text{O}$ were obtained by Christensen (J. pr. [2] 35, 57) by dissolving artificially prepared MnO in HFAq , filtering through spongy Pt, evaporating, and placing over H_2SO_4 . Boiling or diluting the solution of MnO in HFAq produces an oxyfluoride.

The double salts $\text{Mn}_2\text{F}_7 \cdot 4\text{KF} \cdot 2\text{H}_2\text{O}$, $\text{Mn}_2\text{F}_7 \cdot 4\text{NH}_4\text{F}$, $\text{Mn}_2\text{F}_7 \cdot 4\text{NaF}$, and $\text{Mn}_2\text{F}_7 \cdot 2\text{AgF} \cdot 8\text{H}_2\text{O}$ are described by Christensen (l. c. and *ibid.* p. 161). They are obtained by adding solution of the alkali fluoride to solution of Mn_2O_3 or MnO_2 in HFAq , washing with water containing HF , and drying on Pt; the Ag salt is obtained by dissolving freshly ppd. Ag_2CO_3 in HFAq , adding Mn_2F_7 in HFAq , and evaporating. According to Christensen, the salt $\text{Mn}_2\text{F}_7 \cdot 4\text{KF} \cdot 2\text{H}_2\text{O}$ is identical with the compound to which Nicklès gave the formula $\text{MnF}_2 \cdot 2\text{KF}$ (C. R. 65, 107).

MANGANESE TETRA- and HEPTA- FLUORIDES, MnF_4 and Mn_2F_7 (?). The former compound was supposed by Nicklès to exist in the solution of MnO in HFAq (C. R. 65, 107); by adding KF or NaF the double salts $\text{MnF}_2 \cdot 2\text{K}(\text{Na})\text{F}$ were said to be formed. The investigations of Christensen (J. pr. [2] 35, 57, 161) have made it very probable that Mn_2F_7 , and not MnF_4 , is formed when MnO_2 or Mn_2O_3 is dissolved in HFAq (v. *supra*; cf. Manganic chloride, *supra*).

The formula MnF_3 was given by Wöhler (P. 3, 619) to a purple-yellow gas obtained by adding conc. H_2SO_4 to a mixture of 2 parts commercial KMnO_4 and 1 part CaF_2 in a Pt retort. The gas dissolves in water to form HMnO_4Aq and HFAq , and on evaporation HF and O are evolved, and MnF_2 remains. The composition of the gas is still very doubtful; no analyses are given in Wöhler's paper.

MANGANO-MANGANIC FLUORIDE, Mn_2F_7 . According to Nicklès (C. R. 67, 448), brown crystals, having the composition $\text{Mn}_2\text{F}_7 \cdot 10\text{H}_2\text{O}$, are obtained by reacting on MnO with warm HFAq and evaporating.

Manganese, haloid compounds of. The compounds MnX_4 ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$) have been isolated. Mn_2F_7 has also been obtained in definite form. There are very strong reasons in favour of the existence of Mn_2Cl_7 in the solutions obtained by dissolving Mn_2O_3 or MnO in cold conc. HClAq .

The existence, even in solution, of tetra-haloid compounds, MnX_4 , is doubtful. Nickles claims to have obtained mangano-manganic fluoride Mn_2F_7 corresponding with Mn_2O_7 . The only haloid compound of Mn which has been gasified is $MnCl_4$. The general formula MnX_3 probably expresses the atomic composition of the molecules of the more stable haloid compounds of Mn; the formula Mn_2X_3 may or may not be molecular. The existence of hepta-haloid compounds MnX_7 might be expected from the position of Mn in the periodic scheme of classification; but the existence of these compounds is extremely doubtful.

Manganese, hydroxides of, v. Manganese, oxides and hydrated oxides of; for $HMnO_3$, v. Manganese, oxyacids of.

Manganese, iodide of. MnI_4 . Obtained, with $4H_2O$, in rose-red deliquescent crystals, isomorphous with $MnCl_4 \cdot 4H_2O$, by dissolving $MnCO_3$ in $HIAg$, and evaporating. Turns brown when exposed to air and light; heated in absence of air, it is not decomposed; heated in O it burns like tinder, evolving vapours of I . Thomsen gives the thermal data $[Mn, I^2, Ag] = 75,700$ (Th. 3, 271).

Manganese, oxides and hydrated oxides of. The oxides MnO , Mn_2O_3 , Mn_3O_4 , MnO_2 , probably also MnO , and Mn_2O_3 , have been isolated. A number of oxides intermediate between Mn_2O_3 and MnO_2 , having the general form $xMnO_{2-y}MnO$, also exist. Hydrates of most of these oxides exist, but their stability is generally small. $Mn_2O_3 \cdot H_2O = H_2Mn_2O_4$ is known; it is an acid. The acid corresponding to MnO_2 (H_2MnO_4) has not been isolated, but salts of this acid (manganates) are known. The oxides MnO , Mn_2O_3 , and Mn_3O_4 are basic. MnO reacts with acids to form manganous salts MnX_2 ($X = NO_3, \frac{1}{2}SO_4$, &c.); Mn_2O_3 forms manganic salts Mn_2X_3 , which are readily reduced to MnX_2 ; Mn_3O_4 does not form corresponding salts, but with acids yields MnX_2 and Mn_2X_3 , or in some cases MnX_3 and MnO_2 . Nickles, however, asserts the production of Mn_2F_7 by the action of $HFAg$ on Mn_2O_3 (v. *Mangano-manganic fluoride*, p. 180). MnO_2 reacts with acid to form manganic salts Mn_2X_3 , or manganous salts MnX_2 , according to temperature. It is possible that a few salts corresponding with MnO_2 may exist, but their isolation is doubtful. MnO_2 also combines with some oxides more basic than itself to form *manganites*, salts of the form $xMO \cdot yMnO_2$. MnO_2 is very unstable; it does not form salts. The existence of $(MnO_2)_2SO_4$ is probable. With water MnO_2 forms $H_2Mn_2O_4$ and MnO_2 . Mn_2O_3 is very unstable; with water it forms permanganic acid, $H_2Mn_2O_4$.

The molecular weight of none of the oxides of Mn is known with certainty, as none has been gasified.

Manganous oxide, MnO . (*Manganese monoxide or protoxide*.) S.G. 5.09, crystalline (Rammelsberg); 5-18, *manganosite* (Blomstrand, B. 8, 180).

Occurrence.—In small quantities, as *manganosite*, in bright green hexagonal forms (Blomstrand, l.c.).

Preparation.—1. By heating to redness in a Pt vessel a mixture of equal parts $MnCl_2$ and Na_2CO_3 , with a little NH_4Cl ; $MnCO_3$ is formed

and then decomposed, the formation of higher oxides is prevented by the NH_4Cl ; the residue is washed and dried (Liebig & Wöhler, P. 21, 578). 2. By heating any of the higher oxides of Mn, very finely divided, to redness in a stream of H until the powder is green. According to Wright & Menke (C. J. 37, 28), pure MnO can be thus obtained, even from specimens of MnO_2 containing c. 10 p.c. of potash.—3. $MnCO_3$ or Mn_2CO_3 is strongly heated in absence of air, and the product is then heated in H (Liebig, A. 95, 116).—4. Deville (C. R. 53, 199) obtained MnO in bright green regular octahedra by heating MnO_2 in H containing a very little HCl .

Properties and Reactions.—A grass-green powder; Deville's crystalline specimen (v. *supra*) formed lustrous, diamond-like, green regular octahedra. According to Moissan (A. Ch. [5] 21, 199, 251), MnO prepared by reduction of higher oxides by CO at 140° is pyrophoric. When pure, MnO does not oxidise by exposure to air (Wright & Menke, C. J. 37, 28 note); but if it contains minute quantities of potash oxidation occurs. Heated in air or O , Mn_2O_3 is produced; if the heating is done carefully till the weight is constant at dull redness, Mn_2O_3 is produced (v. Gorgeu, C. R. 106, 743). MnO melts at white heat in absence of air. It is not reduced by heating in H or CO , or with C at 500° – 600° (Wright & Luff, C. J. 33, 523). When heated in H_2S , MnS and H_2O are formed. MnO reacts with acids to form manganous salts, MnX_2 ($X = NO_3, ClO_3, \frac{1}{2}SO_4, \frac{1}{2}PO_4$, &c.).

HYDRATE OF MANGANOUS OXIDE, $MnO \cdot H_2O$. Occurs in small quantities in Sweden, in white crystalline tablets, as *pyrochroïte*. Prepared, as small white hexagonal prisms, by adding 300 grm. KOH in 500 c.c. air-free water to an air-free solution of 15-17 grm. crystallised $MnCl_2$ in 15 c.c. air-free water, in a vessel filled with H or coal-gas, heating to 160° , and allowing to cool (A. de Schulten, C. R. 105, 1265). Rapidly oxidises in air. When a manganous salt is present the compound $2MnO \cdot MnO_2 \cdot xH_2O$ is formed; when exposed to O for several years the product is $MnO_2 \cdot MnO$ (Gorgeu, C. R. 108, 948). When NH_4Ag is added to solution of a manganous salt, $MnO \cdot H_2O$ is not pptd., as it is soluble in NH_4Ag ; but this solution rapidly absorbs O from the air, and after a time all the Mn is pptd. as hydrates of Mn_2O_3 . The presence of NH_4 salts hinders the oxidation process; solutions of double NH_4 -Mn salts are scarcely changed in air if free NH_3 is absent. Thomsen gives the thermal data: $[Mn, O, H^2O] = 94,770$; $[MnO \cdot H^2O] = 21,560$; $[MnO \cdot H^2, \frac{1}{2}SO_4 Ag] = 26,480$ (Th. 3, 271).

MANGANO-MANGANIC OXIDE, Mn_2O_3 . (*Red oxide of manganese*.)

Occurrence.—As *hausmannite*, in small brownish-black tetragonal forms, $a:c = 1:1.1537$; S.G. 4.8.

Preparation.—1. Pure $MnCl_2$ is pptd. by Na_2CO_3 , the pp. is thoroughly washed, dried, and then heated to whiteness for some time until the weight is constant (cf. Wright & Luff, C. J. 33, 520, with Reissig, A. 103, 27).—2. By strongly heating Mn_2CO_3 in air (Lassaigne, A. Ch. [8] 40, 329).—3. Crystals of *hausmannite* were obtained by Debray by strongly heating a mixture of $MnSO_4$ and K_2SO_4 in a Pt crucible (C. R. 52, 985); also by passing a very slow stream of HCl

over amorphous Mn_2O_3 heated to redness (Deville, *C. R.* 63, 199); also by keeping molten $MnCl_2$ in an atmosphere laden with moisture (Gorgeu, *C. R.* 96, 1044); also by melting amorphous Mn_2O_3 with borax (Nordenskjöld, *P.* 114, 112; v. also Debray, *Ann. M.* [5] 1, 124; Sidot, *C. R.* 69, 201; v. Hauer, *J. pr.* 63, 425; Ebell, *D. P. J.* 220, 64, 155).

It is generally stated that Mn_2O_3 is produced by heating any of the other oxides of Mn to redness in air; according to the experiments of Dittmar (*C. J.* 1864, 294) the composition of the product of heating MnO_2 in a mixture of O and N varies according to the pressure of the O; if the pressure of the O is about 19 atmos. the product is approximately Mn_2O_3 , while if the pressure of the O is greater than about 26 atmos. the product approximates more or less closely to Mn_2O_3 . The experiments of Wright and Luff (*C. J.* 83, 520), on the effect of heating $MnCO_3$ in air, showed that unless the heating is continued for a long time and the temperature is kept very high the product contains more O than Mn_2O_3 . According to Gorgeu (*C. R.* 106, 743), finely powdered Mn_2O_3 can be oxidised to $\alpha MnO_2 \cdot \gamma MnO$, finally to Mn_2O_3 , by heating in air.

Properties and Reactions.—A reddish-brown solid powder; crystalline Mn_2O_3 is brown. S.G. crystalline 4.856, amorphous 4.018. Mn_2O_3 is not changed when heated to a very high temperature. It is reduced to MnO by H, CO, and C (Bell, *C. N.* 23, 258; Müller, *P.* 136, 160); reduction by CO begins at c. 100°, by H at c. 240°, and by C at c. 420° (Wright and Luff, *C. J.* 33, 520). Mn_2O_3 with conc. H_2SO_4 forms a solution containing $MnSO_4$ and $Mn_2(SO_4)_3$; when the acid is hot, only $MnSO_4$ is formed and O is evolved. With boiling HNO_3 Aq, $Mn(NO_3)_2$ and MnO_2 are produced. Hot conc. HCl Aq produces $MnCl_2$ and evolves Cl. Fused with alkalis, alkaline manganate is formed. Cl in presence of an alkaline solution reduces an alkaline permanganate. The reactions of Mn_2O_3 with acids, $KIAg$, &c., suggest the constitution $2MnO \cdot MnO_2$ (Pickering, *C. J.* 35, 657).

HYDRATES OF MANGANO-MANGANIC OXIDE. $Mn_2O_3 \cdot xH_2O$. Such hydrates appear to exist, but their composition varies. Gorgeu (*C. R.* 84, 177) says a yellowish-green hydrate is formed by shaking an aqueous solution of a manganese salt with alkali in presence of air. Hydrates of Mn_2O_3 are also said to be formed by placing finely-powdered MnO_2 in excess of an ammoniacal solution of $MnCl_2$ and heating (cf. J. Otto, *A.* 93, 372). Veley (*C. J.* 41, 63) obtained a substance nearly agreeing in composition with the formula $8Mn_2O_3 \cdot 31H_2O$, by heating $\alpha MnO_2 \cdot \gamma MnO \cdot xH_2O$ in H to 200°.

MANGANIC OXIDE, Mn_2O_3 . (*Sesquioxide of manganese*.)

Occurrence.—As *braunite* in quadric octahedra; S.G. 4.752 (Rammelsberg, *P.* 124, 513). The hydrate $Mn_2O_3 \cdot H_2O$ occurs native as *manganite*.

Preparation.—1. The pp.—approximately $MnO_2 \cdot xH_2O$ —obtained by passing Cl into Na_2CO_3 Aq holding finely-powdered $MnCO_3$ in suspension, is made into a thin cream with conc. H_2SO_4 and slowly heated on an oil-bath to 100°, at which temperature O is suddenly evolved, and the mass becomes thicker and

grayish-violet in colour; it is then heated to 138° until it is dark green. The impure $Mn_2(SO_4)_3$, thus produced is placed on a warm porous plate, by which H_2SO_4 is absorbed; it is then rubbed with conc. HNO_3 Aq, free from HNO_2 , again dried on a porous tile, and then warmed to 130°. The $Mn_2(SO_4)_3$, thus produced is exposed to air, when it rapidly deliquesces to form a violet solution, which afterwards becomes turbid from separation of $Mn_2O_3 \cdot H_2O$ ($Mn_2(SO_4)_3 + 4H_2O = Mn_2O_3 \cdot H_2O + 3H_2SO_4$). The brown solid which separates is washed, dried at 100° and then gently heated until the water is removed (Carius, *A.* 98, 53).—2. According to Schreider (*P.* 107, 605), Mn_2O_3 is obtained by heating MnO_2 , MnO , or Mn_2O_3 in O (but v. account of Dittmar's experiments under *Manganomanganic oxide, supra*). Moissan says that artificially prepared MnO_2 goes to Mn_2O_3 when heated in O to 230° (*A. Ch.* [5] 21, 232). According to Berthelot (*A. Ch.* [5] 15, 185) and Knab, Mn_2O_3 is obtained by heating $MnCl_2$, $MnBr_2$, or MnI_2 in air or O. This oxide is also said to be formed, with evolution of O, by passing H_2O vapour over heated K_2MnO_4 . Gorgeu (*C. R.* 108, 1106) obtained Mn_2O_3 by allowing ppd. $MnCO_3$ to remain in contact with aerated water for 10 years; also by exposing $MnO \cdot H_2O$ to O in presence of excess of a mangano-salt; also by exposing solutions of $MnSO_4$, $MnCl_2$, and $Mn(C_2H_3O_2)_2$ to sunlight.

Properties and Reactions.—A black powder, S.G. 4.325; the mineral *braunite* forms brownish-black, very hard, lustrous quadric octahedra, S.G. 4.752. Deoxidised at white heat to Mn_2O_3 . Soluble in conc. H_2SO_4 , forming a reddish liquid, which evolves O on warming, and then contains $MnSO_4$; boiled with dilute H_2SO_4 Aq or HNO_3 Aq, MnO_2 is separated, and mangano-sulphate or nitrate goes into solution (Christensen, *J. pr.* [2] 28, 1). Soluble in cold conc. HCl Aq, forming a brown liquid, which most probably contains Mn_2Cl_4 (v. *Manganic chloride*, p. 180).

Mn_2O_3 is a basic oxide; the corresponding salts are not numerous, they are readily reduced to mangano-salts. $Mn_2(SO_4)_3$ combines with alkali sulphates to form alums. Mn_2O_3 reacts with hot HCl Aq, with $KIAg$, and other reagents, as if it were $MnO \cdot MnO_2$ (Pickering, *C. J.* 35, 657). Laugier (*C. R.* 104, 1508) describes several compounds of Mn_2O_3 with SeO_2 , prepared by the reaction of MnO_2 with H_2SeO_4 Aq.

HYDRATE OF MANGANIC OXIDE, $Mn_2O_3 \cdot H_2O$. Occurs native as *manganite*; S.G. 4.335; isomorphous with *gibbsite* and *diaspore*, the corresponding Fe and Al compounds. The preparation of $Mn_2O_3 \cdot H_2O$ is described under *Manganic oxide* (v. *supra*); it forms a brownish-black powder. Warmed with conc. H_2SO_4 to c. 100°, $Mn_2(SO_4)_3$ is formed without evolution of O (Carius, *A.* 98, 53). According to Carius (*l.c.*), $Mn_2O_3 \cdot H_2O$ is not dissolved by dilute H_2SO_4 Aq even on gently warming; but if a little MnO is present solution occurs in the cold. $Mn_2O_3 \cdot H_2O$ is said by Hermann (*P.* 74, 303) to dissolve in tartaric acid, forming a brownish-red liquid, from which mangano-sulphate separates on standing, the liquid becoming colourless and now containing formic acid and CO_2 . In a stream of H_2S , a little $MnSO_4$, and also MnS

and Mn_2O_3 , are formed (Wagner, *D. P. J.* 195, 532). When moist $Mn_2O_3 \cdot H_2O$ is shaken with *magnesia alba*, K_2CO_3 , or Na_2CO_3 , or even with water, and much As_2O_3 , nitrates are produced according to Reichardt (Henneberg's *J. für Landwirthsch.* 26, 167).

MANGANESE PEROXIDE, MnO_2 . (*Manganese dioxide.*)

Occurrence.—As *pyrolusite*; in iron-black, opaque, rather brittle trimetric crystals, $a:b:c = .776:1:1.066$; S.G. 4.82 to 4.97. The name is supposed to have been given from the use of the mineral to remove the colour from glass coloured by compounds of iron ($\pi\pi p$ = fire, and $\lambda\epsilon\iota\upsilon\upsilon$ = wash out).

Preparation.—Pure MnO_2 is dissolved in as small a quantity as possible of dilute HNO_3 Aq, the solution is evaporated to a syrup, which is heated to 160° – 165° for some hours; the product is thoroughly washed with boiling water, then dried over H_2SO_4 , and heated to $c. 180^\circ$ – 200° , until every trace of water is removed. Pure MnO_2 is thus obtained, exactly resembling *pyrolusite* (Gorgeu, *C. R.* 88, 796; Wright a. Menke, *C. J.* 37, 45; cf. Schlösing, *C. R.* 55, 284; and Kuhlmann, *D. P. J.* 211, 25). Even if the $Mn(NO_3)_2$ used contain a large quantity of KNO_3 , MnO_2 practically free from K_2O is obtained by this method.

Very many attempts have been made to obtain pure MnO_2 by ppn. from Mn salts; e.g. by ppg. with $BrAq$ in presence of Na acetate, by passing Cl into an alkaline solution containing $MnCO_3$ in suspension, by reacting on a Mn salt solution with $KMnO_4$ Aq, &c. The various methods have been examined by Gorgeu (*C. R.* 88, 796; *A. Ch.* [3] 66, 153); Guyard (*Bl.* [2] 1, 89); Hannay (*C. J.* 33, 269; cf. Beilstein a. Jawein, *B.* 12, 1530); Pickering (*C. J.* 35, 654); Volhard (*A.* 198, 318); Kessler (*J. r.* 18, part 1); Pattinson (*C. J.* 35, 365); Veley (*C. J.* 37, 581); Wright a. Luff (*C. J.* 33, 504); and Wright a. Menke (*C. J.* 37, 22). The outcome of the work is that pure MnO_2 cannot be obtained by any of the ppn. methods; either the pp. is $xMnO_2 \cdot yMnO$, or, if all the Mn is present as MnO_2 , the pp. contains also K_2O or some other base besides H_2O . Volhard's method—adding excess of $KMnO_4$ Aq to $MnSO_4$ Aq in presence of HNO_3 (exact quantities are given by V.)—gave all the Mn as MnO_2 , accompanied by a small quantity of K_2O (c. 3 p.c.), which could not be removed by washing (W. a. M., *L. c.*).

Properties.—A black, or brownish-black, hard, crystalline powder. S.G. 5.02. Heated to moderate redness, Mn_2O_3 is formed; heated to whiteness, Mn_2O_3 remains (cf. *Mangano-manganese oxide; Preparation*, p. 182). MnO_2 is a conductor of electricity; it is strongly electro-negative to the metals. Reacts with acids to form salts corresponding with MnO_2 ; with cold conc. $HClAq$ most probably, forms Mn_2Cl_8 .

Reactions.—1. Heated, gives Mn_2O_3 at moderate redness, and Mn_2O_4 at white heat.—2. Heated in hydrogen, or carbon monoxide, is reduced to MnO ; reduction in H begins at $c. 190^\circ$, and in CO at $c. 87^\circ$; when heated with carbon reduction begins at $c. 850^\circ$ (Wright a. Luff, *C. J.* 33, 518).—3. Heated with *potassium chlorate*, O is evolved and MnO_2 and KCl remain;

a little Cl is evolved, and at one stage of the change $KMnO_4$ is produced. The reaction between MnO_2 and $KClO_3$, probably produces $KMnO_4$, Cl, and O; the $KMnO_4$ then decomposes to K_2MnO_4 , MnO_2 , and O; and the K_2MnO_4 reacts with Cl to form KCl, MnO_2 , and O. The following equations are given by McLeod as expressing approximately the various changes:

- (1) $2MnO_2 + 2KClO_3 = 2KMnO_4 + Cl_2 + O_2$;
- (2) $2KMnO_4 = K_2MnO_4 + MnO_2 + O_2$;
- (3) $K_2MnO_4 + Cl_2 = 2KCl + MnO_2 + O_2$ (v. McLeod, *C. J.* 55, 184; Hodgkinson a. Lowndes, *C. N.* 59, 63; Fowler a. Grant, *C. J.* 57, 272; Baudrimont, *J. Ph.* [4] 14, 84, 161; Warren, *C. N.* 58, 247; Veley, *T.* 1888 [1], 271; Spring a. Prost, *Bl.* 1889, 340).—4. With hot conc. *sulphuric acid*, $MnSO_4$ is formed and O evolved.—5. With cold conc. hydrochloric acid, Mn_2Cl_8 is very probably produced; on warming, Cl is evolved and $MnCl_2$ remains (cf. *Manganic chloride*, p. 180).—6. Heated with *sulphuric acid* and *oxidisable bodies*, MnO_2 acts as an oxidiser; e.g. $H_2C_2O_4$ is thus oxidised to CO_2 and H_2O .—7. Not acted on by moderately dilute *nitric acid* alone; but in presence of an *oxidisable body*, $Mn(NO_3)_2$ and oxidised products are formed, e.g. with HNO_3 and HCl , Cl is evolved.—8. Compounds of Mn_2O_3 with SeO_2 were obtained by Laugier (*C. R.* 104, 1508), by heating ppd. MnO_2 with *selenious acid*.—9. With *hydrogen peroxide* and an acid, forms a salt of MnO and H_2O and evolves O; with *hydrogen peroxide* alone, O is evolved and the same quantity of MnO_2 remains as was originally used (v. *Hydrogen peroxide; Reactions* 11 and 19, vol. ii. pp. 723, 724).—10. Heated with *magnesium chloride*, $MnCl_2$ and MgO are formed and Cl is evolved.—11. Fused with *alkalis* in presence of air or oxygen, *manganates*, M^1MnO_4 , are formed (v. *Manganates* under *Manganese, oxyacids* of, p. 185).

12. MnO_2 combines with a number of *basic oxides* to form salts of the form $xMnO_2 \cdot yMnO_2$, known as *manganites*. According to Gorgeu (*A. Ch.* [3] 66, 153) MnO_2 decomposes neutral solutions of many salts of Ca, Ba, Ag, and Mn, making the solutions acid to litmus and combining with the bases. From dilute solutions of K_2CO_3 and Na_2CO_3 , MnO_2 withdraws and combines with 7 p.c. K_2O , and 4.1 p.c. Na_2O , respectively, according to Gorgeu; the *manganites* thus produced approximately correspond with the formula $M_2O \cdot 15MnO_2$. According to Jolles (*Chem. Zeitung*, 1, 1394) K_2MnO_4 is obtained, as a brown-yellow solid, by mixing equivalent quantities of K_2MnO_4 and C_2H_5O . Wright and Menke (*C. J.* 37, 22) have examined the *potassium manganites* formed by ppg. MnO_2 in presence of K salts, by passing Cl into K_2CO_3 Aq holding $MnCO_3$ in suspension, by adding $MnSO_4$ Aq to $KMnO_4$ Aq, &c.; they conclude that the amount of K_2O ppd. in combination with MnO_2 varies according to the relative masses of the reacting bodies, the temperature, the quantity of free acid present, &c., and that it tends to the maximum $5MnO_2 \cdot K_2O$. W. a. M. failed to obtain $8MnO_2 \cdot K_2O \cdot 3H_2O$ described by Stingl a. Morawski (*J. pr.* [2] 18, 91) as produced by acting on $KMnO_4$ Aq with a reducing agent such as SO_2 , glycerin, or alcohol; they say that K_2O is ppd. in combination with MnO_2 , but that the ratio of K_2O to MnO_2 varies much. Weldon (*C. N.* 20,

109) gave the formula CaO.MnO_2 and CaO.2MnO_2 to the *manganites* formed by oxidising $\text{MnO.H}_2\text{O}$ by air in presence of lime. *Manganites* of the form MO.5MnO_2 , where $\text{M} = \text{Ca, Ba, Sr, Zn, and Pb}$, are described by Bisler (*Bl.* [2] 80, 110) as produced by heating KMnO_4 with slight excess of various metallic chlorides, and washing with water. By heating metallic chlorides with MnO_2 , and then adding MnCl_2 , Rousseau obtained *manganites*, which he classes as MO.5MnO_2 , MO.MnO_2 , and 2MO.MnO_2 (*C. R.* 101, 167; cf. also Post, *B.* 12, 1484, 1537; Rammelsberg, *B.* 8, 283; Rousseau, *C. R.* 102, 425, 615; 103, 261; 104, 786, 1796). Various compounds of MnO with MnO_2 seem to exist; these may be regarded as *manganese manganites*; v. *Oxides intermediate between manganic oxide and manganese peroxide, infra*.

18. While MnO , reacts as an acidic oxide towards the oxides of the more positive metals, it also reacts as a basic oxide with some acids. The usual reactions of MnO , with acids are those of a basic peroxide (v. *Reactions*, 3 to 6, *supra*). The salt $\text{MnO}_2.\text{SO}_3$ is said by Fremy to be formed by carefully reacting on $\text{MnO}_2.x\text{H}_2\text{O}$ with conc. H_2SO_4 , and allowing to stand in air (*C. R.* 82, 476). By adding MnSO_4 to a freshly prepared solution of PbO_2 in acetic acid, as long as PbSO_4 was pptd., Schönbein (*J. pr.* 74, 325) obtained a deep brownish-red liquid, which had strongly oxidising properties, and from which MnO_2 separated on standing, or more quickly on boiling. Schönbein thought that this liquid contained an acetate of MnO_2 , but he did not succeed in isolating this salt.

HYDRATES OF MANGANESE PEROXIDE. When approximately pure MnO_2 is pptd., by oxidising manganous salts in alkaline solutions, or by reactions between manganous salts and permanganates, or by decomposing KMnO_4 by H_2SO_4 or HNO_3 , the pp. always contains water; but it is very doubtful whether any definite, and fairly stable hydrate of MnO_2 exists. When the process of formation results in ppn. of all the Mn as MnO_2 , the composition of the pp. approximates to $\text{MnO}_2.x\text{H}_2\text{O}$, but this body loses water in dry air (v. Wright a. Menke, *C. J.* 37, 22). When the whole of the Mn is not pptd. as MnO_2 , the pp. consists of compounds of the form $x\text{MnO}_2.y\text{MnO}.z\text{H}_2\text{O}$ containing variable quantities of metallic oxides according to the conditions of formation. It appears to be possible to obtain hydrates which are stable for many hours within definite limits of temperature, but these hydrates are of the form $x\text{MnO}_2.y\text{MnO}.z\text{H}_2\text{O}$ (v. Veley, *C. J.* 37, 581; 41, 56).

OXIDES INTERMEDIATE BETWEEN MANGANIC

OXIDE AND MANGANESE PEROXIDE. These oxides belong to the general formula $x\text{MnO}_2.y\text{MnO}$. The composition of the pp. obtained by adding water to solutions of MnO_2 , or Mn_2O_3 , in cold conc. HClAq varies between $16\text{MnO}_2.5\text{MnO}$ and $86\text{MnO}_2.5\text{MnO}$ (Pickering, *C. J.* 85, 659). By passing Cl for a limited time into solution of Mn acetate, Veley obtained a pp. approximating in composition to $5\text{MnO}_2.\text{MnO}.x\text{H}_2\text{O}$ (*C. J.* 37, 581; 41, 56); by heating this pp. in a current of air, the compound $11\text{MnO}_2.\text{MnO}.x\text{H}_2\text{O}$ was produced; and by heating the first compound in O, the body produced had the composition $23\text{MnO}_2.\text{MnO}.2\text{H}_2\text{O}$. Wright a. Menke (*C. J.* 37, 22) obtained a number of bodies $x\text{MnO}_2.y\text{MnO}.z\text{H}_2\text{O}$ by various processes of oxidising manganous salts, and reducing permanganates; in every case, however, K_2O , or other alkali, was held in combination. Further accounts of these intermediate oxides, many of which were probably mixtures of the better defined oxides of Mn, will be found in the memoirs referred to under **HYDRATES OF MANGANESE PEROXIDE** (v. *supra*), especially in the memoirs of Gorgeu.

MANGANESE TRIOXIDE, Mn_2O_3 . This compound is formed, in very small quantities, by slowly dropping a solution of KMnO_4 in cold conc. H_2SO_4 (c. 6 grams KMnO_4 in 100 c.c. H_2SO_4) on to dry Na_2CO_3 . The Na_2CO_3 is placed in a distilling flask surrounded by cold water. The flask is connected with a U-tube filled with fragments of glass, and surrounded by a mixture of ice and salt, and this tube is connected with another U-tube containing a little dilute $\text{H}_2\text{SO}_4\text{Aq}$. As each drop of the green solution of KMnO_4 in H_2SO_4 falls on to the Na_2CO_3 , a pink cloud is formed; the cloud partly condenses in the first U-tube, and part of it passes on and is dissolved in the H_2SO_4 in the second tube (Franke, *C. J.* [2] 36, 81, 166; v. also Thorpe a. Hambly, *C. J.* 53, 175). Only a very small quantity of Mn_2O_3 can be obtained. It appears as a reddish, amorphous, deliquescent mass. It slowly decomposes at ordinary temperatures, but is fairly stable if surrounded by ice and salt (T. a. H., *l. c.*). Mn_2O_3 is decomposed by water yielding HMnO_2Aq and MnO_2 (T. a. H.); according to Franke, H_2MnO_3 is produced, but quickly decomposes to MnO_2 , O, and HMnO_2 , and probably also $\text{H}_2\text{Mn}_2\text{O}_7$. Mn_2O_3 dissolves in conc. H_2SO_4 , forming a green solution. Franke thinks this liquid contains $(\text{MnO}_2)_2\text{SO}_4$. Mn_2O_3 dissolves in KOH Aq , forming KMnO_4 . Mn_2O_3 liberates I from KI, and acts on Hg similarly to ozone (T. a. H.).

MANGANESE HEPTOXIDE, Mn_2O_7 . (*Permanganic anhydride*.) This oxide was obtained by Thenard (*C. R.* 42, 362). Its composition was determined by Aschoff (*J. pr.* 81, 34). Pure KMnO_4 , free from Cl compounds, is added little by little to conc. H_2SO_4 , S.G. 1.845, kept cold by a freezing mixture. To the green solution thus obtained a few drops of water are added, when Mn_2O_7 slowly separates in dark reddish-brown oily drops. If acid of the composition $\text{H}_2\text{SO}_4.\text{H}_2\text{O}$ (S.G. c. 1.78) is used, oily drops of Mn_2O_7 are formed without addition of water. According to Franke (*J. pr.* [2] 86, 81), a solution of KMnO_4 in conc. H_2SO_4 contains $(\text{MnO}_2)_2\text{SO}_4$, and this is decomposed by a little water, giving Mn_2O_7 and H_2SO_4 .

Tatell (*Bl.* 1862, 40) prepares Mn_2O_3 by dissolving $KMnO_4$ in well-cooled H_2SO_4 , containing water in the ratio $H_2SO_4 : H_2O$, placed in a stoppered retort, the neck of which passes into a glass balloon surrounded by a freezing mixture. Corks or organic material must not be used in any part of the apparatus. He heats the retort to 60° – 65° (not over 70°), when purple-red vapour is evolved and condensed to a thick greenish-black liquid, which is Mn_2O_3 . Only a few drops of Mn_2O_3 can thus be prepared at a time. As soon as a certain quantity collects in the balloon, decomposition occurs, with slight detonation (v. also Spiess, *J. pr.* [2] 1, 421).

P. Thenard (*J. pr.* 69, 58) describes Mn_2O_3 as a dark olive-green liquid, with a smell recalling Cl compounds and ozone. Aschoff (*J. pr.* 81, 34) describes it as dark brownish-red oily drops, which do not solidify at -20° . Mn_2O_3 slowly decomposes in air at ordinary temperatures, with evolution of O. It may be heated to 60° – 65° , under reduced pressure, without volatilising; at a somewhat higher temperature it is suddenly and violently decomposed to MnO_2 and O. Mn_2O_3 is very hygroscopic. It dissolves in water to form a purple liquid, probably containing $HMnO_3$. This liquid is slowly decomposed on warming into MnO_2 and O. Mn_2O_3 dissolves in conc. H_2SO_4 , apparently without decomposition, to form an olive-green liquid (this liquid contains $(MnO_3)_2SO_4$ according to Franke, *J. pr.* [2] 36, 31). Mn_2O_3 is at once decomposed by contact with small quantities of MnO_2 , Ag_2O , or HgO (Aschoff, *l. c.*). Mn_2O_3 is a powerful oxidiser. It inflames paper or alcohol.

MANGANESE RETROXIDE (?). Franke (*J. pr.* [2] 36, 31, 166) states that a blue gas is obtained by leading air or CO_2 , saturated with water at 40° – 50° , over the green liquid formed by dissolving $KMnO_4$ in well-cooled conc. H_2SO_4 . To this blue gas he gives the formula MnO_3 . Thorpe and Hambley repeated Franke's experiments (*O. J.* 53, 178), but failed to obtain any indications of the formation of a blue gas.

Manganese, oxyacids of, and their salts. Two series of salts derived from oxyacids of Mn are known—the *manganates* $Mn^{VI}MnO_4$, and the *permanganates* $Mn^{VII}MnO_4$. The acid corresponding to the manganates, viz. H_2MnO_4 , has not been isolated, but its anhydride MnO_3 is known. The anhydride of permanganic acid, viz. Mn_2O_7 , is known, and the acid itself has also probably been isolated.

MANGANATES, $Mn^{VI}MnO_4$, derived from the hypothetical acid H_2MnO_4 . The anhydride of this acid, viz. MnO_3 , is known. A solution of this oxide in water perhaps contains H_2MnO_4 , but it decomposes almost at once to $HMnO_3$ and MnO_2 (v. *Manganese trioxide*, p. 184). When an acid is added to solution of a manganate, the manganic acid produced at once decomposes to permanganic acid and MnO_2 . This change occurs even when CO_2 is passed into solution of a manganate. The manganates are isomorphous with the sulphates.

The fact that the product of fusing together pyrolusite, potash, and saltpetre dissolved in water to form a green liquid, which became blue, violet, and then red, on addition of much water, was known to Scheele. To the green substance Scheele gave the name '*Chamæleon minerale*.'

Chevillot and Edwards, in 1817, showed that the green substance was a definite compound of potash with an acid of Mn (*A. Ch.* [2] 4, 287; 8, 337). Forchhammer (*Annals of Phil.* 16, 310; 17, 150) and Frömmherz (*P.* 81, 677) investigated the manganates. Mitscherlich, in 1830, showed that two salts are obtained by the action of alkali on pyrolusite in presence of air or alkali nitrate (*P.* 25, 287).

Manganates of the alkalis and alkaline earths are obtained by heating MnO_2 with KOH , $CaO.H_2$, &c., to c. 150° in absence of air, or to higher temperatures in presence of air, or by strongly heating any Mn salt with KOH , $CaO.H_2$, &c., in presence of O or an oxidiser, e.g. $KClO_3$. K_2MnO_4 and Na_2MnO_4 dissolve without decomposition in water containing alkali. In pure water, $KMnO_4$ or $NaMnO_4$ is formed and MnO_2 ppt. Solutions of the alkali manganates are decolourised, with ppt. of MnO_2 , by easily oxidised bodies, e.g. $SO_2.Aq$, $As_2O_3.Aq$, H_2SAq , or ferrous salts. Ba and Sr manganates are insoluble in water.

Barium manganate $BaMnO_4$. A dark-green powder. S.G. 4.85. Insol. water. Unchanged in air; decomposed by acids. Prepared by calcining $Ba(NO_3)_2$ with MnO_2 , or by projecting finely-powdered MnO_2 into a molten mixture of $KClO_3$ and $BaO.H_2$, washing with hot water, and drying. By heating MnO_2 with $Ba(NO_3)_2$, $BaMnO_4$ is obtained as a green powder consisting of minute hexagonal crystals (Forchhammer, *Annals of Phil.* 16, 130; 17, 150; Rosenstiel, *J. Ph.* 46, 544; Schafarik, *J. pr.* 90, 16). The salt is also obtained by digesting $Ba(MnO_3)_2$ with $BaO.Aq$.

Didymium manganate $Di_2(MnO_4)_3$. A black powder; insol. water. Obtained by heating for 30 minutes 1 pt. MnO_2 with 4 pts. Di_3NO_3 , and washing with water (Friedrichs & Smith, *A.* 191, 353).

Lanthanum manganate $La_2(MnO_4)_3$. Resembles the Di salt; prepared similarly (F. & S. *l. c.*).

Potassium manganate K_2MnO_4 .

Formation.—1. A mixture of equal parts of finely-powdered MnO_2 and KOH is heated to bright redness in air, or in O; $3MnO_2 + 2KOH = K_2MnO_4 + Mn_2O_3 + H_2O$. K_2MnO_4 is formed by heating MnO_2 and KOH in absence of O to c. 150° (Beketoff, *Bl.* 1, 43); the reaction occurs in N at c. 180° (Elliot & Storer, *P. Am. A.* 5, 192). If the mixture is heated above 180° O must be present, because at c. 190° K_2MnO_4 is decomposed with re-formation of MnO_2 .—2. By boiling conc. $KMnO_4$ with $KOH.Aq$; $2KMnO_4.Aq + 2KOH.Aq = 2K_2MnO_4.Aq + H_2O + O$ (Aschoff, *J. pr.* 81, 29). According to Thenard (*J. pr.* 69, 58) this reaction only occurs when the KOH contains some oxidisable substances, e.g. a little organic matter.—3. By long-continued heating $KMnO_4$ to 240° ;

$2KMnO_4 = K_2MnO_4 + MnO_2 + O_2$ (Thenard, *l. c.*).—4. By fusing any oxide of Mn with KOH in presence of O, or an oxidiser such as $KClO_3$.

Preparation.—2 pts. KOH are dissolved in the smallest quantity of water, 1 pt. $KClO_3$, and 2 pts. very finely-powdered MnO_2 are added, the mixture is dried, and then heated, nearly to redness, for a long time in a Pt dish; the fused mass when cold is treated with a little water,

the conc. green solution is decanted, after standing until quite clear, and evaporated *in vacuo* over H_2SO_4 .

Properties and Reactions.—Dark-green crystals; isomorphous with K_2SO_4 and K_2CrO_4 . Soluble in water containing KOH without decomposition; dissolves in pure water with decomposition to $KMnO_4$ and MnO_2 . Dilute acids, even CO_2 , quickly decompose K_2MnO_4 , forming K permanganate and a manganous salt; e.g. with H_2SO_4 ;— $6K_2MnO_4.Aq + 4H_2SO_4.Aq = 2K_2Mn_2O_8.Aq + MnSO_4.Aq + 3K_2SO_4.Aq + 4H_2O$. Heated in CS_2 , MnS , CO_2 , and polysulphides of K are formed (Müller, *P.* 127, 404). Heated in a stream of water-vapour, Mn_2O_3 , KOH, and O are produced

($2K_2MnO_4 + 2H_2O = Mn_2O_3 + 4KOH + 3O$). By fusing MnO_2 with KOH in air, and then passing water-vapour over the product, then again fusing the products together, and repeating these processes, O may be obtained from the atmosphere.

Sodium manganate $Na_2MnO_4.10H_2O$. Obtained by long-continued heating equal pts. finely-powdered MnO_2 and $NaNO_3$, boiling with water, filtering, and allowing to cool (Gentele, *J. pr.* 82, 58). Said to form colourless crystals, resembling Glauber's salt, and to dissolve in water with partial decomposition to form a green solution.

PERMANGANIC ACID AND PERMANGANATES. The acid $HMnO_4$, or H_3MnO_4 , has probably been isolated; a series of salts derived from this acid is known. Permanganic anhydride, Mn_2O_7 , is a very unstable liquid; it dissolves in water to form $HMnO_4.Aq$, which slowly decomposes to MnO_2 and O. Permanganic acid and its salts readily part with O, and hence act as energetic oxidisers. The permanganates are isomorphous with the perchlorates $M'ClO_4$; they are purple red; all are soluble in water, the least soluble is the Ag salt. These salts are produced by the action of dilute acids, or of Cl, on the manganates; or by the reaction of several oxidisers, e.g. PbO_2 and dilute $HNO_3.Aq$, on Mn salts:—(Tamm, *J.* 1872, 910; Fresenius, *Fr.* 11, 415, 425; Crum, *A.* 60, 219; Gibbs, *Am. S.* [2] 14, 204; Chatard, *C. N.* 24, 196; Pichard, *C. R.* 75, 1821; Deshayes, *Bl.* [2] 29, 541; Volhard, *A.* 198, 354; Rose, *P.* 105, 289). $KMnO_4$ is reduced to K_2MnO_4 by boiling conc. $KMnO_4.Aq$ with potash (*cf.* POTASSIUM MANGANATE, *Formation* No. 2, p. 185). Solutions of permanganates are decomposed by $NH_4.Aq$ with separation of $xMnO_2.yMnO$; they are reduced to manganous salts by $HNO_3.Aq$, fairly conc. $HCl.Aq$, $SO_2.Aq$, $Na_2S_2O_4.Aq$, many organic compounds, &c. H_2SO_4 decomposes solid permanganates with separation of MnO_2 and evolution of O. Solutions of $HMnO_4$ and $KMnO_4$ absorb the green and yellow-green rays of the spectrum; the absorption-spectrum has been examined by Lecoq de Boisbaudran (*Spectres lumineux*, p. 108). According to Vogel (*B.* 8, 1534) $\frac{1}{1000}$ pt. of Mn may be detected, in presence of Cu and Fe compounds, by boiling with PbO_2 , or Pb_2O_3 and dilute $HNO_3.Aq$ free from Cl compounds, and examining the absorption-spectrum of the solution (of permanganate) produced.

Ammonium permanganate NH_4MnO_4 . Resembles $KMnO_4$, with which it is isomorphous; v. sol. water; decomposed by gently

heating. Prepared by rubbing together Ag_2MnO_4 and $NH_4Cl.Aq$ in the ratio $Ag_2MnO_4:NH_4Cl$, filtering, and evaporating at the ordinary temperature over H_2SO_4 ; also by decomposing $BaMnO_4$ by $(NH_4)_2SO_4$ (Böttger, *N. R. P.* 25, 115).

Barium permanganate $BaMnO_4$. Small, hard, rhombic octahedra; almost black, with violet sheen. Prepared by adding excess of $H_2SiF_6.Aq$ to $KMnO_4.Aq$, filtering from K_2SiF_6 , through asbestos, saturating with $BaO.Aq$ containing $BaO_2.H_2O$ in suspension ($BaCO_3$ should not be used as it causes ppn. of $MnO_2.xH_2O$), decanting from $BaSiF_6$, and evaporating (Rousseau a. Bruneau, *C. R.* 93, 229). Böttger (*N. R. P.* 25, 115) prepares $BaMnO_4$ by dissolving in water the product of the fusion of 2 pts. KOH and 1 pt. MnO_2 , filtering, and adding $BaCl_2.Aq$ until the green colour of the liquid disappears; he collects the violet-blue pp., and washes it with cold water till the washings begin to appear reddish; he heats this pp., which is $Ba(MnO_4)_2$, with water, passes in CO_2 till the liquid is purple-red, filters from MnO_2 , and evaporates.

Calcium permanganate $CaMnO_4.5H_2O$. A crystalline, deliquescent mass; prepared by decomposing $AgMnO_4$ by $CaCl_2.Aq$, following directions given for obtaining NH_4MnO_4 (*v. supra*).

Cobalt permanganate does not seem to have been isolated; but Klobb has prepared several *luteo-cobaltic permanganates*, viz. $Co_2(NH_4)_{12}(MnO_4)_6$, $Co_2(NH_4)_{12}Cl_2(MnO_4)_6$, $Co_2(NH_4)_{12}Br_2(MnO_4)_6$ (*C. R.* 103, 384; *Bl.* [2] 48, 240).

Potassium permanganate $KMnO_4$.

Formation.—1. By fusing together KOH and an oxide of Mn in the air or with $KClO_4$, dissolving the K_2MnO_4 in water, passing in CO_2 , filtering from MnO_2 , and evaporating

($3K_2MnO_4.Aq + 2CO_2 = 2KMnO_4.Aq + 2K_2CO_3.Aq + MnO_2$).—2. By warming solution of a Mn salt with K_2CO_3 and $KClO_4.Aq$.—3. By melting MnO_2 with KHO, making a conc. solution of the fused mass, adding saturated $MgSO_4.Aq$, and filtering

($3K_2MnO_4.Aq + 2MgSO_4.Aq = 2KMnO_4.Aq + 2K_2SO_4.Aq + 2MgO + MnO_2$) (Tessié du Mothay, *D. P. J.* 186, 231).—4. By passing Cl into a solution of the fused mass obtained as in 1 and 3, and evaporating (Städeler, *J. pr.* 103, 107) ($2K_2MnO_4.Aq + Cl_2 = 2KCl.Aq + 2KMnO_4.Aq$).

Preparation.—A mixture of 2 pts. KOH and 1 pt. $KClO_4$ is melted in a thin sheet-iron crucible; the crucible is removed from the lamp, and 2 pts. very finely powdered and sifted MnO_2 are added, little by little; heating is then continued, with stirring, until the mass gets quite hard; the temperature is then raised for a short time to full redness; when cold, the mass is broken up, and boiled with so much water that no crystals separate on cooling (c. 40 pts. water for 1 pt. $KClO_4$ used); a rapid stream of well-washed CO_2 is passed into the boiling liquid until a drop placed on paper makes a red stain (showing no green at the edges), the outer part of which soon becomes brown. After cooling, the greater part of the liquid is poured off, the rest is filtered (from MnO_2) through glass-wool, and the whole is evaporated until a drop placed on a cold surface quickly deposits crystals.

After standing 12 to 24 hours the greater part of the KMnO_4 separates out; a little is obtained by further evaporating the mother-liquor. 100 grms. pyrolusite give about 30 grms. KMnO_4 (Böttger, *J. pr.* 90, 156; for modification of this method, v. Gräber, *J. pr.* 96, 169; Wöhler, *P.* 27, 626; Gregory, *J. Ph.* 21, 312; Mitscherlich, *P.* 25, 287; Elliot a. Storer, *P. Am. A.* 5, 192). Béchamp (*A. Ch.* [3] 57, 293) heats MnO_2 with KOH , and oxidises by passing O over the fused mass; he then dissolves in water, passes in CO_2 , and evaporates.

Properties.—Dark purple-red, almost black, rhombic crystals; $a:b:c = 79523:1:6478$. S.G. 2.71 (Kopp). Isomorphous with KClO_4 . S. at $15^\circ = 6.25$ (Mitscherlich). Decomposed by heat, giving K_2MnO_4 and O . Pure conc. KMnO_4Aq can be boiled without change; in presence of oxidisable bodies KMnO_4Aq is quickly reduced.

Reactions.—1. Heated to 240° , MnO_2 , K_2MnO_4 , and O are produced (Chevillot a. Edwards, *A. Ch.* [2] 4, 290). At higher temperatures $x\text{MnO}_2.y\text{K}_2\text{O}$ is formed (Rousseau, *C. R.* 104, 786).—2. *Sulphuric or nitric acid* separates HMnO_4 , which decomposes with evolution of O and ppn. of MnO_2 , Mn_2O_3 , or $x\text{MnO}_2.y\text{MnO}$; with considerable excess of warm $\text{H}_2\text{SO}_4\text{Aq}$ or HNO_3Aq , MnSO_4 or $\text{Mn}(\text{NO}_3)_2$ is produced. Cold conc. H_2SO_4 dissolves KMnO_4 , forming a green liquid, from which a few drops of water cause separation of Mn_2O_3 (cf. *Manganese heptoxide*, p. 184; v. also *Manganese trioxide*, p. 184).—3. *Hydrochloric acid* in excess forms MnCl_2 and evolves Cl . Dry HCl evolves Cl , and forms H_2O , KCl , $\text{Mn}_2\text{O}_3.x\text{H}_2\text{O}$, MnCl_2 , and probably Mn_2Cl_4 (Thomas, *C. J.* 33, 372).—4. *Sulphuric acid* and *oxidisable bodies* either separate MnO_2 , or $x\text{MnO}_2.y\text{MnO}$, the oxidisable body being simultaneously oxidised; or if there be enough acid to prevent ppn. of $x\text{MnO}_2.y\text{MnO}$, MnSO_4 is formed. With $\text{H}_2\text{C}_2\text{O}_4$ and H_2SO_4 , CO_2 and H_2O (besides K_2SO_4 and MnSO_4) are produced (cf. Berthelot, *A. Ch.* [5] 21, 176; Harcourt, *C. J.* [2] 5, 460; Jones, *C. J.* 33, 95). Harcourt (l.c.) represents the reaction thus:

Jones (l.c.) says that H_2O , $\text{K}_2\text{C}_2\text{O}_4$, and $\text{Mn}_2\text{C}_2\text{O}_4$ are at first produced on adding KMnO_4Aq to $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, and that further addition of KMnO_4Aq forms K_2CO_3 , ppts. Mn_2O_3 , and evolves CO_2 and O . Alcohol gives Kacetate and a pp. containing MnO_2 , MnO , and K_2O ; glycerin gives a similar pp. and forms K_2CO_3 (Morawski a. Stingl, *J. pr.* [2] 18, 78; cf. Berthelot, l.c.).—5. According to Aschoff (*J. pr.* 81, 29) conc. KMnO_4Aq is reduced to K_2MnO_4 by boiling with *potash solution* ($2\text{KMnO}_4\text{Aq} + 2\text{KOH}\text{Aq} = 2\text{K}_2\text{MnO}_4\text{Aq} + \text{H}_2\text{O} + \text{O}$); Thenard (*J. pr.* 69, 59) says that this action does not occur unless traces of oxidisable substances, e.g. organic matter, are present.—6. KMnO_4Aq acidified by H_2SO_4 reacts with *hydrogen peroxide* to form H_2O , O , and MnSO_4 . At low temperatures, c. 12° , the KMnO_4 is decolourised, but O is not evolved, according to P. Thenard (*C. R.* 75, 177); Berthelot (*A. Ch.* [5] 21, 176) thinks that H_2O_2 (?) is formed (v. also Swiontowski, *A.* 141, 205; Aschoff, *P.* 111, 217).—7. KMnO_4Aq is decomposed with separation of MnO_2 , Mn_2O_3 , or $x\text{MnO}_2.y\text{MnO}$, by *ammonia* (Cloëz a. Guignet,

C. R. 47, 710; Wöhler, *A.* 136, 256; Wanklyn a. Gamgee, *C. J.* [2] 6, 25; Tamm, *C. N.* 25, 47); by *hydrogen* (Jones, *C. J.* 33, 96; Wanklyn a. Cooper, *P. M.* [5] 6, 288); by *phosphine*, *arsine*, and *stibine* (Jones, l.c.; Schobig, *J. pr.* [2] 14, 239; Parsons, *C. N.* 1877, 236); by *chlorine dioxide* [ClO_2] (Fürst, *A.* 206, 75).—8. With *potassium sulphocyanide*, K_2SCN , and KCNO are produced (Morawski a. Stingl, *J. pr.* [2] 18, 78).—9. *Sodium thiosulphate* in boiling solution is wholly oxidised to Na_2SO_4 by fairly conc. KMnO_4Aq ; if the KMnO_4Aq is very dilute from 1 to $2\frac{1}{2}$ p.c. $\text{Na}_2\text{S}_2\text{O}_3$ remains (Gläser, *M.* 7, 651).

Combination.—From conc. mixed solutions of KMnO_4 and K_2MnO_4 , the salt $\text{KMnO}_4.\text{K}_2\text{MnO}_4$ separates in small, six-sided, monoclinic tablets (Gorgeu, *J. pr.* 80, 123).

Sodium permanganate $\text{NaMnO}_4.3\text{H}_2\text{O}$. Formed similarly to KMnO_4 , or by the reaction between AgMnO_4 and NaClAq . V. sol. water, and hence obtained in crystals with difficulty.

Silver permanganate AgMnO_4 . Monoclinic crystals. S. '91 in cold water. Obtained by mixing conc. warm KMnO_4Aq with AgNO_3Aq , and allowing to cool (Dewar a. Scott, *Pr.* 35, 44). Klobb (*C. R.* 103, 381) obtained $\text{AgMnO}_4.2\text{NH}_3$ by saturating KMnO_4Aq with NH_3 , and then adding an equivalent quantity of AgNO_3 .

Permanganates of copper, dysprosium (Erichs a. Smith, *A.* 191, 354), **lanthanum** (F. a. S., l.c.), **lead**, **lithium**, **magnesium**, **strontium**, and **zinc**, have been isolated.

Permanganic acid, HMnO_4 . The solution obtained by decomposing powdered $\text{Ba}(\text{MnO}_4)_2$ by an exactly equivalent quantity of $\text{H}_2\text{SO}_4\text{Aq}$, contains this acid. Hünefeld (*Schweigger's Jahrb. der Chem. und Phys.* 30, 133) says that the acid can be obtained, in indigo-like crystals, by washing $\text{Ba}(\text{MnO}_4)_2$ with hot water, whereby it is decomposed to MnO_2 and BaMnO_4 , filtering, adding exactly enough phosphoric acid to decompose the Ba salt, heating to 60° – 100° , filtering, and evaporating at a low temperature. (No analyses are given.)

Manganese oxychlorides of. Several oxychlorides of Mn appear to exist, but they have not been satisfactorily examined. P. de Saint-Gilles (*C. R.* 55, 329) says that $\text{MnCl}_2.3\text{Mn}_2\text{O}_3$ is formed as a black powder, resembling MnO_2 , by heating to 280° , in a partially closed vessel, a mixture of MnCl_2 and NaNO_3 . Gorgeu (*A. Ch.* [6] 4, 515) obtained an oxychloride, to which he provisionally assigned the formula $\text{MnCl}_2.\text{MnO}$ by heating MnCl_2 in water vapour. According to Aschoff (*J. pr.* 81, 29) the gas which Dumas obtained by adding pieces of fused KCl or NaCl to a mixture of KMnO_4 and conc. H_2SO_4 , and which he said was MnCl_2 , is probably an oxychloride having the composition $\text{Mn}_2\text{O}_3.\text{Cl}$.

Manganese oxyfluoride of. According to Nicklès (*C. R.* 65, 107) the compounds MnOF.KF and $\text{Mn}_2\text{OF}_2.2\text{KF}$ are ppts., when solution of MnO_2 in ethereal HCl is poured into boiling KFAq or NaFAq . Christensen (*J. pr.* [2] 35, 57), however, asserts that the double compound obtained as described above is MnOF_2 .

Manganese oxysulphide of. The compound MnO.MnS is said to be formed, by Arfvedson (*P.* 1, 50), by heating MnSO_4 in H_2 ; it is a green solid, which dissolves in acids with evolution of H_2S ; heated in air it burns to Mn_2O_3 .

Manganese, phosphides of. Several compounds of Mn with P have been described. Mn_2P : an amorphous powder, S.G. 4.94, obtained by heating Mn and P together to low redness (Schrötter, *J. pr.* 51, 385). Also formed, according to H. Rose, by heating $MnCl_2$ in PH_3 . By heating Mn pyrophosphate mixed with sugar-charcoal, in a crucible filled up with charcoal, Struve (*J. pr.* 81, 821) obtained a brittle substance resembling pig-iron, the composition of which varied between Mn_2P_3 and Mn_3P . Merkel and Wöhler (*A.* 86, 371) obtained a crystalline, greyish, regulus, S.G. 5.95, by heating together 10 parts MnO_2 , 10 parts well-burnt bones, 5 parts quartz-sand, and 3 parts lamp-black. The composition agreed with the formula Mn_2P_3 ; but as part was soluble, and part insoluble, in $HClAq$, they regarded the substance as a mixture of two phosphides, Mn_2P_3 (soluble in $HClAq$) and Mn_3P (insoluble in $HClAq$).

Manganese, salts of. Compounds obtained by replacing the H of acids by Mn. Mn forms two series of salts: *manganous salts*, MnX_2 , and *manganic salts*, MnX_3 ; $X = NO_3$, ClO_3 , $\frac{1}{2}SO_4$, $\frac{1}{2}PO_4$, &c. One or two salts of the form MnX_3 —e.g. $Mn(SO_4)_2$ —are also said to exist. The manganous salts are considerably more stable than the manganic salts. A number of double salts of manganic sulphate are known; those with the alkali sulphates are alums, e.g. $Mn_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$. The manganous salts form a fair number of double salts and a few basic salts. The chief salts of Mn are the following: *antimonates*, *arsenates* and *arsenites*, *borates*, *carbonates*, *chlorate* and *perchlorate*, *chromates*, *ferri-* and *ferro-cyanides*, *iodate*, *nitrolybdate*, *nitrate* and *nitrites*, *phosphates* and *phosphites*, *selenates* and *selenites*, *silicates*, *sulphates* and *sulphites*, *thiosulphate*, *tungstate*, *vanadate*: v. CARBONATES, NITRATES, SULPHATES, &c.

Manganese, selenide of. Said to be produced in combination with H_2O as a red powder, decomposed in air, by adding an alkali selenide solution to solution of a manganous salt.

Manganese, silicides of. Mn and Si combine when heated together (Troost a. Hautefeuille, *C. R.* 81, 264). Silicides of Mn, containing from 6.5 to 13 p.c. Si, have been obtained by Wöhler (*A.* 106, 54) by fusing together MnF_2 , Na, K silicate, and cryolite; or $MnCl_2 \cdot 2NaCl$, CaF_2 , and K silicate; or $MnCl_2$, CaF_2 , K_2SiF_6 , and Na. These silicides form hard, brittle masses; they dissolve in $HClAq$ with evolution of K and SiH_4 .

Manganese, silicofluoride of. $MnSiF_6 \cdot 6H_2O$. Hexagonal crystals, $a:c = 1:1.515$; S.G. at $17.5^\circ = 1.9038$ (Stolba, *O. C.* 1883, 292). Formed by dissolving $MnCO_3$ or MnF_2 in H_2SiF_6Aq , and evaporating. When heated, the crystals give off water, and then SiF_4 , and leave MnF_2 (Borzelius).

Manganese, sulphides of. Two sulphides are known, MnS and Mn_2S_3 .

Manganous sulphide, MnS . Occurs native, as *manganese-blende*, in hexagonal crystals, S.G. 5.95. Produced by heating together MnO or $MnCO_3$ and S, not by heating S with Mn. Also formed by heating Mn in CS_2 (Gautier a. Hallopeau, *C. R.* 108, 806); also by heating various Mn compounds in H_2S (Carnot, *Bl.* [2] 82, 162). Sidot (*J.* 1868, 229) obtained MnS in hexagonal crystals by heating the amorphous substance in a stream of H_2S . MnS is pptd. from solutions of

Mn salts by NH_4 sulphide, as a pale buff-coloured amorphous solid, which quickly oxidises in air; if this pp. is rapidly dried and then warmed in H_2S , pure MnS is obtained. MnS is a greenish solid; decomposed by weak acids, e.g. acetic acid, with evolution of H_2S . Heated in air, SO_2 is evolved and Mn_2O_3 remains (P. W. Hofmann, *D. P. J.* 181, 364). Heated in H_2O vapour, H_2S and H are given off and Mn_2O_3 is formed. MnS is slowly decomposed by Cl with formation of $MnCl_2$ and S_2Cl_2 .

There appear to be two forms of MnS obtainable by ppn. from Mn salts by NH_4 sulphide: the pp. from conc. $MnCl_2Aq$ or $MnSO_4Aq$ is rose-coloured; if NH_4Cl is present the pp. is greenish and consists of small 8-sided plates. The green sulphide is not produced when K_2S or Na_2S is used as pptant. (Fresenius, *J. pr.* 82, 265; Muck, *Z.* 1869, 580; de Clermont a. Guyot, *Bl.* 27, 353; Geuther, *Z.* 1865, 347). The rose-coloured sulphide is said to be changed to the green sulphide by heating with a little water; but it may be heated to 305° with much water without changing. The change from rose to green is accomplished by heating with NH_4Aq to 250° in a closed tube, and the reverse change by heating in NH_3 gas. The rose sulphide is not changed by heating alone to 250° but in presence of H_2S the green sulphide is formed at 220° (De C. a. G., l.c.). The green sulphide is thought by Muck to be an oxysulphide of Mn.

Double compound, $3MnS \cdot K_2S$. Obtained by heating a mixture of 1 pt. dry $MnSO_4$, $\frac{1}{2}$ pt. lamp-black, and 3 pts. K_2CO_3 and S, and treating the fused mass with water; the compound remains insoluble in water, forming small lustrous dark-red tablets (Voelcker).

Manganic sulphide, Mn_2S_3 . Occurs native as *hauerite*, in large, brown-black, lustrous, regular octahedra, S.G. 3.463. Said to be obtained as a red amorphous powder, by heating $MnSO_4Aq$ with solution of K polysulphides to 160° – 180° in a closed tube (Sparmann, *J. pr.* 51, 385). Not changed in air; decomposed by acids.

Manganese, sulphocyanide of, v. vol. ii. p. 350. M. M. P. M.

MANGANITES. Salts in which MnO_2 acts as the acidic radicle; v. *Manganese peroxide*, *Reactions* 12, under MANGANESE, *Oxides* and *hydrated oxides of*, p. 183.

MANGANOCYANIDES v. vol. ii. p. 342.

MANGOSTIN $C_{20}H_{26}O_2$, [c. 190°]. Contained in the husk of the fruit of *Garcinia mangostana*. The dry husks are boiled with water to extract tannin, then treated with hot alcohol, and the alcoholic extract left to evaporate. The mangostin which is deposited is dissolved in alcohol and pptd. by lead subacetate. The pp. is decomposed by water and the mangostin finally crystallised from dilute alcohol (Schmid, *A.* 93, 83). Thin golden laminae without taste or smell. Insol. water, v. sol. alcohol and ether. Warm dilute acids dissolve it without alteration. Hot conc. HNO_3 gives oxalic acid. Alkalis dissolve it with yellowish-brown colour. Reduces chloride of gold solution. $FeCl_3$ gives a dark greenish-black solution, decolourised by acids. Its solution is not pptd. by any metallic salt except lead subacetate.— $(C_{20}H_{26}O_2)_2 \cdot 5PbO$ (dried at 100°): pptd. by adding alcoholic lead acetate and ammonia to an alcoholic solution of mangostin.

MANNITE $C_6H_{12}O_6$.

$OH(OH)OH(OH)OH(OH)OH(OH)OH(OH)OH(OH)$.
Mol. w. 182 (181 by Raoult's method, Brown & Morris, *Q. J.* 53, 620). $[155^\circ]$. S.G. 1.5. $[\alpha]_D^{20} = -25$. S. 15.6 at 18° (Berthelot, *A. Ch.* [3] 47, 801); 13 at 14° (Krusemann, *B. J.* 1467); 16 at 16.5° (Wanklyn & Erlenmeyer, *J.* 1862, 480). S. (alcohol) $.07$ at 14° . H.C. v. 728, 200. H.C. p. 728, 500 (Berthelot & a. Vieille, *Bl.* [2] 47, 868; *A. Ch.* [6] 10, 456). H.F. 318, 500 (B. a. V.); 287, 000 (Von Reichenberg).

Occurrence.—Discovered by Proust (*A. Ch.* [1] 57, 143). Occurs to the extent of 30 to 60 p.c. in manna, the dried juice which exudes from the manna ash (*Eragrostis Ormus*). Mannite occurs in many other plants, e.g.: the roots of *Aconitum napellus*; Celery, *Apium graveolens*; *Meum athamanticum*; *Eranthis crocata*; *Poly-podium vulgare*; *Scorzonera hispanica*, and *Triticum repens*; and in the root-bark of *Tunica granatum*. Mannite also occurs in the bark of *Canella alba* (8 p.c.), and of *Eragrostis excelsior*; in the leaves and young twigs of *Syringa vulgaris*; in the leaves of *Ligustrum vulgare* and of *Cocos nucifera*, and in the fruit of *Laurus Persea* and of *Cactus opuntia*. Mannite also occurs in *Laminaria saccharina*, in olives, and in several fungi, e.g.: *Lactarius vellereus*, *L. turpis*, *L. pyrogalus*, and *L. pallidus*. *Agaricus integer* contains 20 p.c. of its dry substance. It also occurs in the cambium layer of *Conifera* (Payen, *A.* 12, 60; Meyer & a. Reiche, *A.* 47, 234; Stenhouse, *A.* 51, 349; Knop & a. Schnerdmann, *A.* 49, 293; Döpping & a. Schlossberger, *A.* 52, 117; Müntz, *C. R.* 76, 649; 82, 210; Smith, *J.* 1850, 536; Roussin, *J.* 1851, 550; Ludwig, *J.* 1857, 503; De Luca, *J.* 1861, 740; 1862, 505; Thörner, *B.* 12, 1635; Reinsch, *J.* 1863, 612; Bourquelot, *C. R.* 108, 568; Kachler, *M.* 7, 410).

Formation.—1. In the lactic fermentation of sugar (Liebig, *J.* 1847, 466; Pasteur, *J.* 1857, 511; Dragendorff, *Ar. Ph.* [3] 15, 47).—2. In the viscous fermentation of sugar, 100 pts. of sugar yielding 51 pts. mannite and 46 pts. gum (Pasteur, *J.* 1861, 728).—3. In the spontaneous fermentation of the juice of the sugar-cane in tropical climates (Marcano, *C. R.* 108, 955).—4. By reducing glucose, levulose, or invert-sugar with sodium-amalgam (Linnemann, *A.* 123, 136; Dewar, *P. M.* [4] 39, 345; Bouchardat, *Bl.* [2] 16, 38; Krusemann, *B. J.* 9, 1465; Scheibler, *B.* 16, 8010).—5. By reducing mannose (E. Fischer, *B.* 21, 1808), or 'glucosone' (E. Fischer, *B.* 22, 94), with sodium-amalgam.—6. From the dilactone of meta-saccharic acid by treating with water and sodium-amalgam (3 p.c.), acidifying with H_2SO_4 (Kilian, *B.* 20, 2744; v. LEVOMANNITE, *infra*).

Preparation.—1. Manna is extracted with boiling dilute alcohol, and the crystals which separate on cooling are recrystallised from water.—2. Manna (5 pts.) is boiled with water (1 pt.) after addition of a little white of egg. The crystals which separate from the filtrate are boiled with water (6 pts.) to which some animal charcoal has been added, and the filtrate is allowed to crystallise (Ruspini, *A.* 65, 208).

Properties.—Needles or four-sided prisms. V. sol. water, v. sl. sol. alcohol, insol. ether. An aqueous solution, does not become syrupy on

spontaneous evaporation (difference from sugar).

Only slightly sweet to the taste. It has little, if any, action on light, but if borax be added to the solution it becomes dextrorotatory. Thus in a 10 p.c. solution containing 12.8 g. borax $\alpha = +22.5^\circ$, so that $[\alpha]_D = c + 225^\circ$ (Vignon, *A. Ch.* [5] 2, 483; *C. R.* 77, 1191; Müntz & a. Aubin, *C. R.* 83, 1213; Pasteur, *C. R.* 77, 1192; Bouchardat, *C. R.* 80, 120; 84, 34). Arsenic acid slowly develops levorotation in a solution of mannite. Salts of the alkalis and alkaline earths develop dextrorotation. Free alkalis render the solution levorotatory. A solution containing 8 g. mannite and 8 g. NaOH in 100 c.c. gives $\alpha = -3.4^\circ$, so that $[\alpha]_D = -42^\circ$. A solution of 12 g. mannite and 4 g. sodium tungstate made up to 100 c.c. shows $\alpha = +0.40'$ (Klein, *C. R.* 89, 484). These rotations vary with the amount of dissolved substances. The mannite may be recovered from these solutions without having undergone any change in optical properties. Mannite renders a borax solution acid, forming boric acid and sodium metaborate (Dunstan, *Ph.* [3] 13, 257; 14, 41; Lambert, *C. R.* 108, 1016). Mannite does not reduce Fehling's solution. It hinders the ppn. of ferric and cupric salts by potash. It is not turned brown by boiling KOHAq. With a solution of ammonio-sulphate of copper it gives a blue pp., sol. in ammonia, forming a blue solution which is not affected by boiling (Guignet, *C. R.* 109, 528, 645). Mannite does not reduce boiling solutions of silver or mercurous nitrates, of $HgCl_2$, or of chloride of gold; but it reduces Ag_2O and silver acetate (Hirzel, *A.* 131, 50). When alcohol is added to a solution of mannite mixed with lime, strontia, or baryta-water, pps. $(C_6H_{12}O_6)_2CaO$, $(C_6H_{12}O_6)_2SrO$, and $(C_6H_{12}O_6)_2BaO$ are formed (Hirzel, *A.* 131, 50; cf. Ubaldini, *A. Ch.* [3] 57, 213). Ammoniacal lead acetate gives a pp. On adding to an aqueous solution of mannite (1 mol.) and of lead nitrate (2 mols.) sufficient ammonia to neutralise two-thirds of the nitric acid present in the salt, a voluminous white pp. separates, which, if filtered off and dried over calcium chloride, forms a white crystalline powder $C_6H_6O_6Pb(NO_3)_2 \cdot 2H_2O$, S. 1:10 at 14° ; decomposing with explosion on heating, and separated into its constituents on long boiling with water and by carbonic anhydride with formation of lead carbonate (Smolka, *M.* 6, 198).

Reactions.—1. Mannite begins to sublime at c. 200° ; in a sealed tube it is unaltered at 250° . At 280° it splits up into water and mannitan $C_6H_{12}O_5$. When distilled *in vacuo* it yields isomannitan $C_6H_{12}O_5$.—2. A mixture of HNO_3 and H_2SO_4 forms the nitrate, so-called 'nitro-mannite' (Flores Domonte & a. Menard, *J.* 1847, 1145).—3. Nitric acid oxidises it to saccharic, racemic, and oxalic acids, no mucic acid being formed (Backhaus, *J.* 1860, 522; Carlet, *J.* 1861, 367).—4. Boiling HIAq gives sec-hexyl iodide (Wanklyn & a. Erlenmeyer; Domac, *M.* 2, 809; cf. Le Bel & a. Wassermann, *C. R.* 100, 1589).—5. Boiling conc. HClAq slowly forms mannitan.—6. Potash-fusion yields formic, acetic, and propionic and oxalic acids and acetone (Gottlieb, *A.* 52, 122).—7. On oxidation with $KMnO_4$ in alkaline solution it gives oxalic acid, formic acid, a little tartaric acid, a sugar which reduces Fehling's solution, and erythric acid $C_6H_8O_6$, which forms

the salts CaA' , 2aq , BaA' , 2aq , and $\text{C}_4\text{H}_2\text{BaO}$, 2aq (Hecht a. Iwig, *B. 14*, 1790; 19, 468; cf. Fabst, *C. R.* 91, 728, who states that he obtained a dibasic acid $\text{C}_4\text{H}_2\text{O}_4$, which he names dioxyisocitric acid).—8. Air and platinum black yield mannitic acid $\text{C}_4\text{H}_8\text{O}_4$, and mannitose $\text{C}_6\text{H}_{12}\text{O}_6$.—9. MnO_2 and H_2SO_4 give formic acid and acrolein (Backhaus).—10. When mannite (2 pts.) is heated with 80 p.c. formic acid (5 pts.) for 8 hours a mixture of formyl derivatives of mannitan appears to be formed. This mixture yields on distillation CO , CO_2 , isomannide $\text{C}_4\text{H}_{10}\text{O}_4$, a liquid $\text{C}_4\text{H}_8\text{O}_4$ (?) (157° at 17 mm.) and a liquid $\text{C}_4\text{H}_6\text{O}$ (108°), S.G. $\frac{2}{3}$ 9396; $[\alpha]_D = -168^\circ$; almost insol. water, and smelling like a carbamine and mustard oil (Fauconnier, *C. R.* 100, 914; cf. Henninger, *B. 7*, 264).—11. Distillation with oxalic acid yields formic acid, a formyl derivative of mannite or of mannitan being probably first formed (Lorin, *Bl.* [2] 24, 437).—12. Electrolysis of a solution of mannite acidulated by H_2SO_4 yields hydrogen, CO_2 , CO , oxygen, tri-oxy-methylene (? formic paraldehyde or mannitose), formic acid, oxalic acid, and a small quantity of an acid whose calcium salt is $\text{C}_4\text{H}_4\text{CaO}_4$, 2aq . This acid having reducing properties may be

(Rénard, *A. Ch.* [5] 17, 316).—13. PCl_5 gives tetra-chloro-hexinene (Bell, *B. 12*, 1273).—14. PI_2 forms methylene iodide (Butlerow, *A. 111*, 247).—15. Organic acids (e.g. acetic and butyric) heated with mannite at 200° form alkoyl derivatives of mannitan.—16. Mannite heated with water suffers no change below 280°, but at that temperature a viscid product is got containing 'mannitic ether' $\text{C}_4\text{H}_8\text{O}_{11}$ ($[\alpha]_D = -5.6^\circ$) and 'mannitone,' a crystalline isomeride of mannitan. Both bodies are reconverted into mannite by heating with water at 295° (Vignon).—17. Mannito does not react when heated with acetic, valeric, or benzoic aldehydes (Locherer, *A. Ch.* [6] 16, 65). But when acetic aldehyde is passed into a solution of mannite in H_2SO_4 or HClAq the aldehyde is absorbed and there is formed a compound crystallising in needles [174°]; insol. cold water. S. 1 at 95°. It is sl. sol. cold, v. sol. hot, alcohol. Boiling dilute (2 p.c.) H_2SO_4 resolves it into aldehyde and mannite. Paraldehyde gives the same compound. When a mixture of acetic and benzoic aldehydes is used the above product is formed first (Meunier, *C. R.* 108, 408).—18. When a mixture of mannite (10 g.), absolute alcohol (20 g.), and fused ZnCl_2 (5 g.) is saturated with HCl , left for two days, and then mixed with benzoic aldehyde, there is formed 'tribenzoic mannitoid' $\text{C}_6\text{H}_8\text{O}_3(\text{C}_6\text{H}_5\text{O})_3$ [207°]. This crystallises from benzene, and is insol. water, sl. sol. alcohol. It is not affected by boiling alcohol or KOH , but dilute H_2SO_4 yields mannite and benzoic aldehyde (Meunier, *C. R.* 106, 1425, 1732). A solution of mannite in HClAq or H_2SO_4 also reacts with benzoic aldehyde (Meunier, *C. R.* 107, 910).—19. A solution of mannite in alcohol containing ZnCl_2 and saturated with HCl reacts with BzCl , forming di-benzoyl-mannide $\text{C}_6\text{H}_8\text{O}_3(\text{OBz})_2$ [132°] (Meunier, *C. R.* 107, 346).—20. Valeric aldehyde, ZnCl_2 , and HCl convert mannite in alcoholic solution into $\text{C}_6\text{H}_8\text{O}_3(\text{C}_4\text{H}_9\text{O})_2$, which is deposited as silky needles [91°] (Meunier).—21. Not fermented by yeast. In contact with water, chalk, and cheese at 40° it gives

alcohol, carbonic, lactic, butyric, and acetic acids, and hydrogen, but no sugar or glycerin (Berthelot, *J.* 1866, 664). When the fermentation is induced by a slit testicle a fermentible sugar is produced. Upon fermentation by Schizomycetes in presence of CaCO_3 and ammonium phosphate there is formed alcohol, *n*-butyl alcohol, butyric, lactic, acetic, hexoic, and succinic acids (Fitz, *B. 10*, 281; 11, 43). *Bacillus butyricus* gives similar products. Under other conditions formic acid is among the products of fermentation (Fitz, *B. 11*, 1895; 15, 876; 16, 845).—22. Heating with phenyl cyanate forms $\text{C}_4\text{H}_7(\text{OH})(\text{O.CONHPh})$, [260°] (Tessmer, *B. 18*, 968).

Pentanitrate $\text{C}_4\text{H}_7(\text{ONO})_2\text{O}$. Pentanitroxylderivative. [79°]. S. 2 at 60°. S. (alcohol, S.G. 81) 150 at 12°. S. (ether) 130 at 9°. Formed, together with nitro-mannitan, by passing NH_3 into an ethereal solution of the hexanitrate (Tichanovitch, *J.* 1864, 582). Long needles. Dextrorotatory. Explodes when struck, and also, more feebly, when heated. Ammonium sulphide reduces it to mannite.

Hexanitrate $\text{C}_4\text{H}_7(\text{ONO})_3\text{O}$. Nitro-mannite. Mol. w. 452. [113°] (Socoloff). S.G. $\frac{2}{3}$ 1604. S. (alcohol of S.G. 81) 3 at 12.8°. S. (ether) 5 at 9° (Tichanovitch). $\alpha = +12.4$ in a 3 p.c. solution, so that $[\alpha]_D = +400^\circ$ (Müntz a. Anbin). Prepared by treating mannite (1 pt.) with HNO_3 (5 pts. of S.G. 1.5) at 0°, and adding H_2SO_4 (10 pts.). The product is collected on a filter, washed with water and aqueous Na_2CO_3 , and recrystallised from alcohol (Domont a. Menard, *J.* 1847, 1145; Sobrero, *A. 64*, 397; Strecker, *A. 73*, 62; Socoloff, *J. R.* 11, 136). Beautiful white needles, insol. water, sol. alcohol and ether. Explodes violently on being struck—it also explodes when suddenly heated; but if carefully heated it may be decomposed without explosion. Ammonium sulphide converts it into mannite (Dessaignes, *A. 81*, 251). Iron and acetic acid and HIAq also convert it into mannite (Béclamp, *A. Ch.* [3] 46, 354; Mills, *J.* 1864, 584). NH_3 passed into its ethereal solution forms crystalline $\text{C}_4\text{H}_8\text{O}(\text{NH}_2)_2$ (Tichanovitch).

Di-sulphuric acid $\text{C}_4\text{H}_7(\text{SO}_3\text{H})_2(\text{OH})$. From mannite and conc. H_2SO_4 (Favre, *B. 7* 25, 560). The free acid is decomposed by boiling water. It gives no pp. with BaCl_2 or CaCl_2 .— $\text{Pb}_2\text{C}_4\text{H}_7\text{S}_2\text{O}_{12} \cdot 2\text{PbO}$: insoluble pp.

Tri-sulphuric acid $\text{C}_4\text{H}_7(\text{SO}_3\text{H})_3(\text{OH})$. From mannite and conc. H_2SO_4 (Knop a. Schnedermann, *A. 57*, 135). Both the acid and its salts are decomposed by water into mannite and H_2SO_4 .— $\text{Na}_3\text{A}'''$.— $\text{K}_3\text{A}'''$: deliquescent gummy mass; insol. alcohol.— $\text{Ba}_3\text{A}'''$: crystalline powder, sol. water, insol. alcohol.— $\text{Pb}_3\text{A}_3'$: amorphous deliquescent mass.

Tetra-sulphuric acid $\text{C}_4\text{H}_7(\text{SO}_3\text{H})_4(\text{OH})$. $[\alpha]_D = +9^\circ$. Obtained when, in the preparation of the hexa-sulphuric acid, the neutralisation with BaCO_3 is delayed for two days.— Ba_4A^v .

Hexa-sulphuric acid $\text{C}_4\text{H}_7(\text{SO}_3\text{H})_6$. $[\alpha]_D = +24^\circ$. Formed by adding mannite in small portions to chloro-sulphuric acid (ClSO_3H). The product is dropped upon ice, and the ice-cold solution neutralised with BaCO_3 .— Ba_6A^vi 5aq. When alcohol is added to its solution this salt is thrown down as an oil, which

presently changes to a crystalline mass insol. water. The other salts are very soluble, and do not behave thus (Claesson, *J. pr.* [2] 20, 10).

Boric acid. When mannite (4 pts.) is heated with boric acid (8 pts.) for eight hours at 145°, and the product is dissolved in water and neutralised by BaCO₃, a filtrate is obtained which deposits barium borate on evaporating, after which alcohol gives a pp. which, when dried at 100°, has the composition (C₆H₁₂B₂O₁₁)₂Ba (Klein, *Bl.* [2] 29, 863).

Hexa-acetyl derivative C₆H₆(OAc)₆. [119°]. [α]_D = +18° (Bouchardat, *C. R.* 84, 34). From mannite (18 pts.) and Ac₂O (80 pts.) at 180°, with or without addition of a little ZnCl₂ (Bouchardat, *A. Ch.* [5] 6, 107; Schützenberger, *A.* 160, 94; Franchimont, *B.* 12, 2059). Limit of etherification from mannite (1 mol.) and HOAc (6 mols.): 26.4 (Menschutkin, *B.* 13, 1814). Trimetric crystals (from HOAc). Insol. water, cold alcohol, and ether, sl. sol. hot alcohol. Dextrorotatory. May be sublimed in a current of CO₂.

Penta-benzoyl derivative C₆H₅(OBz)₅(OH). [c. 80°]. From mannite (3 g.), water (15 g.), BzCl (20 g.), and NaOH aq. The product is extracted with ether (Skraup, *M.* 10, 394). Amorphous mass.

Hexa-benzoyl derivative C₆H₅(OBz)₆. [140°]. From the preceding and BzCl. Crystalline grains, v. sl. sol. alcohol.

Mannite dichlorhydrin C₆H₈(OH)₂Cl₂. *Dichloro-tetra-oxy-hexane*. [174°]. S. 4.5 at 14°. [α]_D = -3.7. Formed by heating mannite (1 pt.) with conc. HCl aq (6 pts.) at 100° for eight hours (Bouchardat, *C. R.* 75, 1187; 76, 1550; *Bl.* [2] 19, 199). Formed also by heating isomannide with fuming HCl aq at 100° in sealed tubes (Fauconnier, *Bl.* [2] 41, 119). Prepared by heating mannite (1 pt.) with fuming HCl aq (10 pts.) at 106°; evaporating at low temperatures; dissolving the crystals in water; filtering the solution through animal charcoal; and recrystallising from hot alcohol (Siwoloboff, *A.* 233, 368).

Properties.—Monoclinic crystals. Levorotatory. Its aqueous solution is neutral and tasteless, and is not pptd. by AgNO₃. Insol. alcohol and ether. Decomposed on fusion.

Reactions.—1. Boiling water or conc. NaOH aq rapidly convert it into C₆H₈O(OH)₂Cl₂.—2. A mixture of HNO₃ and H₂SO₄ gives C₆H₈(ONO₂)₂Cl₂, which crystallises from hot alcohol in needles [145°], insol. water.—3. *Sodium-amalgam* removes HCl in two stages, forming mannitan chlorhydrin, and finally (β)-mannide [119°].

Mannite dibromhydrin C₆H₈(OH)₂Br₂. [178°]. Obtained by heating mannite with conc. HBr aq for 2 hours at 100° (Bouchardat, *A. Ch.* [5] 6, 120). Small colourless plates (from hot water). Decomposed on fusion. Insol. cold water, alcohol, and ether. Converted by a mixture of HNO₃ and H₂SO₄ into C₆H₈(ONO₂)₂Br₂, which crystallises in long needles, sol. hot alcohol, insol. water.

Mannitan C₆H₁₂O₃, i.e. C₆H₈O(OH)₂. *First anhydride of mannite*. According to Alecian (*J. R.* 16, 383) the various mannitans described below are mixtures of isomannide and other bodies.

(a) **Berthelot's mannitan** C₆H₁₂O₃. Obtained in small quantity by heating mannite at 200°. A better method is by protracted boiling of mannite with conc. HCl aq (Berthelot, *A. Ch.* [3] 47, 806). Slightly sweetish syrup. Differs from mannite in being soluble in absolute alcohol. V. sol. water, insol. ether. Slightly dextrorotatory (Bouchardat, *A. Ch.* [5] 6, 102). When exposed to the atmosphere it is partially reconverted into mannite. Boiling alkalis or dilute acids accelerate the change. Above 140° it partly volatilises.

(b) **Vignon's mannitan** C₆H₁₂O₃. [α]_D = +36.5°. Prepared by heating mannite for an hour or two with half its weight of water at 295°. Also by heating mannite (2 pts.) with conc. H₂SO₄ (1 pt.) at 120°, saturating with BaCO₃, exhausting with alcohol, and evaporating (Vignon, *A. Ch.* [5] 2, 433). Deliquescent mass, v. e. sol. water and absolute alcohol, insol. ether. Does not ferment with yeast. Boiling dilute H₂SO₄ or baryta-water does not reconvert it into mannite. A mixture of mannitan (1 pt.), H₂SO₄ (10° pts.), and HNO₃ (4½ pts. of S.G. 1.5) forms in the cold C₆H₈O₂(OH)(ONO₂), which is obtained on pouring into water and extracting with ether. It is dextrorotatory, [α]_D = +53°.

(c) **Vignon's mannitone** C₆H₁₂O₃. [α]_D = -25°. Obtained by heating mannite with water for 3 hours at 280° and extracting the viscid product with alcohol (Vignon, *A. Ch.* [5] 2, 433). Crystals (from alcohol). Has a sweet taste. Levorotatory. Does not reduce Fehling's solution. In the preparation of this body the syrupy mother-liquor yields a viscid mass, which appears to be the anhydride of mannite or 'mannitic ether' C₁₁H₁₈O₂₁; it does not reduce Fehling's solution, and is levorotatory, [α]_D = -5.6°. This mannitic ether is not converted into mannite or mannitan by boiling dilute acids or alkalis.

(d) **Crystalline mannitan** C₆H₁₂O₃. S. 25 at 15°. When Berthelot's mannitan is allowed to stand for some months in a dry atmosphere it deposits a solid variety (Bouchardat). This crystallises in monoclinic tables. It is strongly levorotatory. Sl. sol. cold alcohol. Boiling water quickly converts it into mannite. This variety of mannitan is probably identical with Vignon's.

Mannitan tetra-nitrate C₆H₈O(ONO₂)₄. Precipitated by adding water to the alcoholic mother-liquor from which mannite pentanitrate has separated (Tichanovitch, *J.* 1864, 583). Syrup, v. sol. alcohol and ether, insol. water. Explodes when struck. Alcoholic KOH converts it slowly into syrupy mannitan.

Di-acetyl derivative C₆H₈O(OH)₂(OAc)₂. [α]_D = +22.6. From mannite and HOAc at 210° (Berthelot). Mannite dissolves in boiling Ac₂O, and on cooling crystals of C₁₁H₁₂AcO₃ separate. Further action of Ac₂O yields hexa-acetyl-mannite and di-acetyl-mannitan (Schützenberger, *A.* 160, 74; Grange, *C. R.* 68, 1326). Extremely bitter substance, v. sol. water, HOAc, and alcohol. Dextrorotatory. Boiling baryta-water converts it into acetic acid and mannitan.

Tetra-acetyl derivative C₆H₈O(OAc)₄. Formed, together with hexa-acetyl-mannite, by heating mannite with Ac₂O at 180° (Bouchardat, *A. Ch.* [5] 6, 110). Amorphous viscid mass, which partially crystallises on long standing.

Insol. water, v. e. sol. alcohol, ether, and HOAc. Dextrorotatory. Aqueous, alkalis at 100° decompose it into acetic acid and mannitan. Ac_2O forms hexa-acetyl-mannite. A mixture of HNO_3 and H_2SO_4 has no action in the cold.

Di-butyl derivative
 $\text{C}_4\text{H}_9\text{O}(\text{OC}_4\text{H}_9)_2(\text{OH})_2$. From mannite and butyric acid at 200° (Berthelot, *C. R.* 88, 673; *A. Ch.* [3] 47, 319). Semi-solid, partly crystalline, mass. Insol. water, v. sol. alcohol and ether.

Tetra-butyl derivative
 $\text{C}_4\text{H}_9\text{O}(\text{OC}_4\text{H}_9)_4$. From mannite and excess of butyric acid at 200°-250°. Oil.

Di-benzoyl derivative
 $\text{C}_6\text{H}_5\text{O}(\text{OBz})_2(\text{OH})_2$. From mannite and HOBz at 200° (Berthelot, *Chimie organique*, 2, 193). Soft resin; v. e. sol. alcohol and ether.

Di-ethyl derivative $\text{C}_2\text{H}_5\text{O}(\text{OEt})_2(\text{OH})_2$. From mannite, KOH, and EtBr at 100° (Berthelot). Syrup, v. sl. sol. water, sol. alcohol, v. e. sol. ether.

Mannitan chlorhydrin $\text{C}_4\text{H}_9\text{O}(\text{OH})_2\text{Cl}$. From mannite dichlorhydrin by boiling for two hours with 100 pts. of water, neutralising with K_2CO_3 , evaporating, and extracting with ether (Bouchardat, *A. Ch.* [5] 6, 118). Solid mass, v. e. sol. water, alcohol, and ether. Dextrorotatory. Conc. HClAq at 100° reconverts it into mannite dichlorhydrin. Boiling water converts it into HCl and mannitan.

Mannitan dichlorhydrin
 $\text{C}_4\text{H}_9\text{O}(\text{OH})_2\text{Cl}_2$. From mannite (1 pt.) and fuming HClAq (15 pts.) by heating for 3 days at 100° (Berthelot, *J.* 1856, 661). Crystals, sol. ether. KOHAq converts it into mannitan.

Mannitan dibromhydrin $\text{C}_4\text{H}_9\text{O}(\text{OH})_2\text{Br}_2$. From mannite dibromhydrin by boiling with water. V. e. sol. water, alcohol, and ether. Dextrorotatory.

Mannide $\text{C}_6\text{H}_{11}\text{O}_6$. Second anhydride of mannite.

(a) **Berthelot's mannide** $\text{C}_6\text{H}_{11}\text{O}_6$. (297°-317°). Obtained by heating mannite with butyric acid at 200°-250° (Berthelot, *A. Ch.* [3] 47, 312; Liebermann, *B.* 17, 874). Thick deliquescent syrup, v. e. sol. cold water and alcohol. Decomposes partially on distillation. In contact with the air it partially forms mannite.

(b) **(β)-Mannide** $\text{C}_6\text{H}_{11}\text{O}_6$. [119°]. (212° at 16 mm.). S. 150 at 15°. S. (alcohol) 2.7 at -16°; 7.8 at 12°. Obtained by treating mannite dichlorhydrin with sodium-amalgam (Sivoloboff, *A.* 233, 368). Prisms; v. e. sol. water and alcohol, insol. ether. Dextrorotatory. Sublimes at 14°, forming long needles. Does not yield mannite when heated with water. Air and platinum-black oxidise it, forming a syrupy liquid.

(c) **Isomannide** $\text{C}_6\text{H}_{11}\text{O}_6$, i.e.

$$\begin{array}{c} \text{O} \quad \quad \text{O} \\ | \quad \quad | \\ \text{CH}_2(\text{OH})-\text{CH}-\text{CH}-\text{CH}-\text{CH}-\text{CH}_2-\text{OH} \end{array}$$

[87°]. (176° at 80 mm.). (274° at 760 mm.). $[\alpha]_D^{20} = +91.4$ in a 6 p.c. aqueous solution. Obtained by distilling mannite *in vacuo*; the product being fractionally distilled *in vacuo* (Fauconnier, *C. R.* 95, 991). Prepared by boiling mannite (200 g.) with HClAq (2,000 g.) for 24 hours; cooling, filtering, and distilling *in vacuo*. The distillate is allowed to stand for a fortnight, extracted with cold alcohol, the extract distilled *in vacuo*, and the frag-

tion boiling at 176° recrystallised from alcohol (Fauconnier, *B.* [2] 41, 119). Large monoclinic, somewhat deliquescent, crystals. Boils at 274° with partial decomposition. V. e. sol. water, m. sol. alcohol, sl. sol. chloroform, insol. ether and benzene. Dextrorotatory. Not affected by heating with water at 150°. By heating with fuming HClAq in sealed tubes at 100° for 25 days it is converted into mannite dichlorhydrin $\text{C}_4\text{H}_9\text{O}(\text{OH})_2\text{Cl}_2$ [174°]. It is not acted upon by POCl_3 , by bromine in the cold, or by sodium-amalgam.

Di-formyl derivative $\text{C}_4\text{H}_7\text{O}_2(\text{OCHO})_2$. [115°]. (166° at 18 mm.). Small plates, sl. sol. cold water, v. sol. alcohol, sol. ether.

Acetyl derivative $\text{C}_4\text{H}_7\text{O}_2(\text{OH})(\text{OAc})$. (186° at 25 mm.). From isomannide and Ac_2O . Colourless oil; sol. ether.

Di-benzoyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OAc})_2$. (198° at 28 mm.). From isomannide (1 pt.) by boiling with Ac_2O (3 pts.) for 8 hours. Viscid liquid, with bitter taste. Not altered by further treatment with Ac_2O .

Di-benzoyl derivative $\text{C}_6\text{H}_5\text{O}_2(\text{OBz})_2$. [132°]. From mannite, alcohol, ZnCl_2 , HCl , and BzCl (Meunier, *C. R.* 107, 346). Monoclinic or triclinic crystals; v. sl. sol. water and cold alcohol, sol. chloroform and benzene. Not decomposed by aqueous acids or alkalis.

Methyl derivative $\text{C}_4\text{H}_9\text{O}_2(\text{OH})(\text{OMe})$. [48°]. (174° at 24 mm.). From isomannide, KOH, MeI , and a little water at 150°. Crystals.

Ethyl derivative $\text{C}_4\text{H}_9\text{O}_2(\text{OH})(\text{OEt})$. (165° at 17 mm.). Formed by heating mannite, EtI , and conc. KOHAq in sealed tubes for 4 hours at 120°. Colourless mobile liquid; sol. water, alcohol, and ether.

Isomannide dichlorhydrin $\text{C}_4\text{H}_9\text{O}_2\text{Cl}_2$. [40°]. (143° at 43 mm.). From isomannide (1 pt.) by warming with PCl_5 (2 pts.). White needles or plates; v. sol. ether, m. sol. alcohol, insol. cold, sol. hot, water. Has a strong aromatic odour and a peppery taste. May be distilled with steam. It is very stable, not being attacked by alcoholic KOH at 150°, by PCl_5 at 125°, or by sodium-amalgam.

Anhydride of mannide $\text{C}_6\text{H}_{11}\text{O}_6$, i.e. $(\text{C}_4\text{H}_9\text{O}_2\text{OH})_2\text{O}$ (?). Deposited on standing from a sample of butyric acid (Genther, *A.* 221, 59). Gummy.

Lævo-mannite $\text{C}_6\text{H}_{11}\text{O}_6$. [164°]. Formed by reducing lævo-mannose with sodium-amalgam. Globular groups of fine needles; v. sol. water, al. sol. absolute alcohol, much more sol. methyl-alcohol. It tastes sweet, and does not reduce Fehling's solution. A solution of this mannite containing borax turns the ray of polarised light to the left. This substance is probably the one obtained by Kiliani (*B.* 20, 2714) by reduction of the double lactone of metasaccharic acid (Emil Fischer, *B.* 23, 375).

Inactive mannite. a-Acrite. [168°]. Formed by reducing inactive mannose with sodium-amalgam. Small prisms (from water), v. sol. water, m. sol. hot glacial acetic acid, al. sol. methyl and ethyl alcohols. It is easily distinguished from ordinary mannite by its crystalline form and by its optical inactivity. A solution containing borax remains wholly inactive. This mannite is identical with (a)-acrite, a substance obtained by the action of sodium-amalgam on

(*a*)-acrose, a sugar obtained by the action of alkalis on acrolein dibromide (Fischer, *B.* 22, 100). By oxidation with dilute HNO_3 , inactive mannose is formed (Emil Fischer, *B.* 23, 383).

The mannites may be distinguished optically by means of their phenyl-hydrazides. 1 g. of the phenyl-hydrazide dissolved in 1 c.c. of cold conc. HClAq and 5 c.c. of water gives in a tube 100 mm. long a rotation of $+1.2^\circ$, -1.2° , and 0° , with the *lævo*-, *dextro*-, and inactive mannite respectively. In the course of 3 or 4 hours the rotation vanishes, the phenyl-hydrazide being decomposed by the HCl . When the di-phenyl-dihydrazide is used 1 g. is dissolved in warm HOAc , cooled, and examined in a 100 mm. tube. It gives a rotation of $+0.85^\circ$, -0.85° , or 0° in the case of the *lævo*-, *dextro*-, and inactive compounds respectively. The *dextro*- and *lævo*-mannites themselves scarcely exhibit a rotation, but 15 g. of the mannite dissolved in 5 c.c. water containing .37 g. borax exhibits a rotation of $+0.85^\circ$, -0.85° , or 0° , according as the mannite is *dextro*-, *lævo*-, or inactive (Fischer).

MANNITIC ACID $\text{C}_6\text{H}_{10}\text{O}_7$. Prepared by mixing mannite (2 g.) with platinum-black (4 g.), moistened with water, and exposing the mixture at 30° to 40° to the air for 3 weeks. The mass is then exhausted with water, the solution ppd. by lead subacetate, the pp. decomposed by H_2S , and the solution evaporated in the cold over H_2SO_4 (Gorup-Besanez, *A.* 118, 257). Gummy mass; sol. water and alcohol, nearly insol. ether. It is a strong acid, and dissolves zinc with evolution of hydrogen. It begins to decompose at 80° . It reduces silver nitrate solution and hot Fehling's solution. It is ppd. by baryta and by lime-water.— CaA'' : amorphous powder, ppd. by adding alcohol to its aqueous solution.— CuA'' : green amorphous mass left by evaporating its solution.— PbA'' : granular.— AgA'' : curdy pp.

MANNITINE $\text{C}_6\text{H}_{12}\text{N}_2$. (170°). Prepared by distilling a mixture of mannite (1 mol.) and ammonium chloride (2 mols.). The distillate is mixed with KOH and shaken with ether (Seichilone a. Denaro, *G.* 12, 416; Etard, *C. R.* 92, 795). Brown oil, with strong odour; sol. alcohol and ether, m. sol. water. Gives an orange-yellow pp. with sodium phosphomolybdate, a reddish-yellow pp. with iodine in KIAq , a pink pp. with HgCl_2 , and a black pp. with auric chloride. Hypodermically injected it produces diminution of the cardiac systole, and irregular respiration, followed by insensibility and death.

MANNITOSE $\text{C}_6\text{H}_{12}\text{O}_6$. Produced, together with mannitic acid, by the atmospheric oxidation of mannite in the presence of platinum-black (Gorup-Besanez, *A.* 118, 273). Optically inactive. Fermentable. Reacts like glucose with alkalis, Fehling's solution, basic bismuth nitrate, and Na_2CO_3 ; but it does not unite with NaCl . Its alcoholic solution gives with alcoholic potash a pp. of $(\text{C}_6\text{H}_{12}\text{O}_6)_2\text{K}_2\text{O}$. Mannitose is perhaps identical with *lævulose* (Dafert, *B.* 17, 228; 19, 911).

MANNONIC ACIDS $\text{C}_6\text{H}_{10}\text{O}_7$.

Inactive mannonic acid. *Lactone* $\text{C}_6\text{H}_{10}\text{O}_6$, [165°]. Formed from inactive mannose by oxidation with bromine (E. Fischer, *B.* 23, 376). Long glittering prisms, grouped in stars or
Vol. III.

needles (from alcohol); v. sol. hot water, sl. sol. hot alcohol. Has a sweet taste and does not reduce Fehling's solution. By means of the strychnine salt it can be split up into *dextro*-mannonic acid and arabinose-carboxylic acid, the strychnine salt of the latter being extremely sl. sol. alcohol. The morphine salts may also be employed, morphine *dextro*-mannonate crystallising out. *Penicillium glaucum* partly decomposes inactive mannonic acid, liberating some arabinose-carboxylic acid— $\text{Ca}(\text{C}_6\text{H}_9\text{O}_7)_2$. Groups of slender needles. Less soluble than calcium *lævo*-mannonate.

Phenyl hydrazide $\text{C}_{12}\text{H}_{11}\text{N}_3\text{O}_7$. [230°]. Colourless cubes, sl. sol. hot water, v. sl. sol. alcohol. Split up by hot baryta-water into phenyl-hydrazine and inactive mannonic acid.

Dextro-mannonic acid. Formed from gluconic acid by heating with twice its weight of quinoline for 40 minutes to 140° (Emil Fischer, *B.* 23, 801). Formed also as above and by oxidation of *dextro*-mannose by bromine. By heating *dextro*-mannonic acid with quinoline, gluconic acid is formed. For this purpose 20 g. of *dextro*-mannonic acid, 5 g. water, and 40 g. quinoline are heated to 140° for 40 minutes. The unchanged mannonic acid is separated by means of its brucine salt. *Dextro*-mannonic acid, like the other mannonic acids, when liberated from its salts condenses at once to the lactone $\text{C}_6\text{H}_{10}\text{O}_6$, [149° – 153°]. Its rotation, $[\alpha]_D = 53.8$, is equal and opposite to that of the lactone of arabinose-carboxylic acid, which is therefore *lævo*-mannonic acid.

Salts.— $\text{Ca}(\text{C}_6\text{H}_9\text{O}_7)_2 \cdot 2\text{aq}$.— SrA' , 3aq .— BaA' , (dried at 100°).

Phenyl hydrazide $\text{C}_{12}\text{H}_{11}\text{N}_3\text{O}_7$. [216°]. Small colourless prisms, v. sol. hot water. Decomposed by hot baryta-water into *dextro*-mannonic acid and phenyl-hydrazine.

Lævo-mannonic acid. *Lactone* $\text{C}_6\text{H}_{10}\text{O}_6$. *Arabinose carboxylic acid*. [145° – 150°]. $[\alpha]_D = -54.8$. Formed from arabinose (v. ARABINIC ACID and SUGARS) by treatment with HCy and saponification of the product (Kiliani, *B.* 19, 3093). Formed also from inactive mannonic acid, as above.

MANNOSE $\text{C}_6\text{H}_{12}\text{O}_6$, i.e.

$\text{CHO}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}_2\text{OH}$.

Dextro-mannose. $[\alpha]_D = +13^\circ$. Formed by heating 3 kilos of mannite with 20 litres of water and 10 litres of HNO_3 (S.G. 1.41) in the water-bath with shaking to 40° – 45° until a test portion rendered neutral with soda gives a thick pale-yellow pp. of the hydrazide with phenyl-hydrazine acetate. The whole is then cooled with ice to about 25° , made feebly alkaline with crystallised Na_2CO_3 , acidified with acetic acid, and treated with 1 kilo of phenylhydrazine dissolved in dilute acetic acid. The phenylhydrazide crystallised from hot water is converted into the sugar by solution in HCl (S.G. 1.19), allowing to stand, cooling, filtering, and neutralising the diluted filtrate with pure carbonate of lead. The whole is again filtered, made alkaline with $\text{Ba}(\text{OH})_2$, and shaken with ether. The aqueous solution separated from ether contains the sugar, which remains as a syrup on evaporating, and is ppd. from absolute alcohol by ether (Emil Fischer a. Josef Hirschberger, *B.* 21, 1806; 22, 365). Mannose may
O

more easily be got from vegetable ivory nuts, *v. SEMINOSE infra*.

Properties.—Light-yellow syrup, with sweet taste. *V. sol.* water, and alcohol. Reduces Fehling's solution; 1 c.c. corresponding to 0.04807 g. of mannose. Turned brown by heating with 20 p.c. HClAq; the solution then containing lactic acid. Ferments easily with yeast, giving CO₂ and alcohol. The aqueous solution is dextrorotatory, but less so than glucose. Sodium-amalgam (2 p.c.) reduces mannose to mannite. Furfuraldehyde is formed by heating a dilute solution of mannose at 110° for four hours. AcCl forms a substance like acetochlorhydrate.

Phenyl hydrazide C₁₂H₁₈N₂O₅. [195°–200°]. S. l. at 100°. Prepared as above. Slender prisms (from water). *Sl. sol.* alcohol and acetone. Its solution in dilute HClAq is levorotatory. Concentrated mineral acids convert it into mannite and phenyl-hydrazine even in the cold. When it is heated with phenyl-hydrazine hydrochloride (3 pts.), NaQAo (4 pts.) and water (80 pts.) at 105° for 4 hours there is formed the 'osazone' of glucose C₁₈H₂₂N₄O₁₁, which crystallises from alcohol in slender yellow needles [206°].

Oxim C₆H₁₁O₄N. Crystalline; *v. sol.* hot water, *insol.* alcohol. When slowly heated it melts at 176°–180°; but when quickly heated, at 184° (Fischer a. Hirschberger, *B.* 22, 1155).

Inactive mannose. Formed by reducing the lactone of inactive mannonic acid with sodium-amalgam (E. Fischer, *B.* 23, 381). Colourless syrup; *v. sol.* water, *sl. sol.* absolute alcohol, *m. sol.* hot methyl alcohol. Resembles (dextro-) mannose except in being inactive. When subjected to fermentation *levo*-mannose is left. Bromine oxidises it to inactive mannonic acid.

Phenyl hydrazide. [195°]. Decomposed on fusion. *Sl. sol.* water. Its solution in HCl is optically inactive. Cold conc. HCl splits it up into sugar and phenyl-hydrazine.

Di-phenyl hydrazide C₁₈H₂₂N₄O₈. [218°]. Formed by heating the inactive mannose with phenyl-hydrazine (2 mols.), the corresponding quantity of acetic acid and water. Fine yellow glittering needles; *sl. sol.* water, cold alcohol, and ether. Decomposes on fusion. At 45° conc. HCl forms the corresponding osone. The solution in 60 pts. glacial acetic acid is optically inactive. The properties of this di-phenyl-hydrazide are the same as those of (α)-acrosazone (the di-phenyl-hydrazide of (α)-acrose), and Emil Fischer (*B.* 23, 383) considers that they are identical.

Levo-mannose. To prepare this body 1 pt. of the lactone of arabinose carboxylic acid is dissolved in 10 pts. water, acidified with H₂SO₄, and cooled to 0°. 2½ p.c. sodium-amalgam is added in small portions. The liquid must remain acid. Colourless syrup; *v. sol.* water, *sl. sol.* absolute alcohol, *m. sol.* methyl-alcohol. The aqueous solution is slightly levorotatory. It ferments little, if at all, with yeast.

Phenyl hydrazide C₁₂H₁₈N₂O₅. [195°]. Formed by adding phenyl-hydrazine acetate to a solution of the sugar. Slender, almost colourless crystals. It is more *sol.* water than the dextro-mannose phenyl-hydrazide. The hydrochloric acid solution is dextrorotatory. Cold HCl splits up the compound into phenyl-hydrazine and mannose

Di-phenyl hydrazide. [205°]. Formed by heating the *levo*-mannose phenyl-hydrazide with phenyl-hydrazine acetate and 30 pts. water to 100°. Fine yellow needles (from water). Decomposed on fusion. It is extremely like the di-phenyl-hydrazide of dextro-mannose, *levulose*, and dextrose. It, however, turns the ray of polarised light strongly to the right (Emil Fischer, *B.* 23, 373).

Isomannitose, a sugar obtained, together with glucose, by boiling salep with acids, is probably identical with mannose (Tollens, *B.* 21, 2150). Its phenyl hydrazide C₁₂H₁₈N₂O₅ [188°] is *sl. sol.* alcohol.

Seminose, obtained by digesting with dilute H₂SO₄ the cellulose composing the thick-walled cells of the endosperm of vegetable ivory nuts, is identical with mannose (Reiss, *B.* 22, 609; Schultz, *B.* 22, 1492; Fischer a. Hirschberger, *B.* 22, 3218).

'Mannose carboxylic acid' C₆H₁₀O₆ *i.e.* C₆H₁₀(CO₂H)₂O₄. From mannose (50 g.) by dissolving in water (250 g.) and adding anhydrous HCl (18 c.c.) and a few drops of ammonia. After three days the mixture is heated to 50° for 4 hours. The product appears to contain the ammonium salt of the acid and its amorphous amide [183°], which may be *ppd.* by alcohol (Fischer a. Hirschberger, *B.* 22, 365). The acid changes to anhydride when set free from its salts. In preparing the lactone (*v. infra*) an acid [c. 169°], probably the free mannose carboxylic acid, is sometimes formed.

Salts.—BaA₂. Obtained by boiling the ammonium salt with baryta. Colourless, semi-crystalline mass, *m. sol.* hot, *v. sl. sol.* cold, water, *insol.* alcohol. Boiling conc. HIAq reduces it slowly to *n*-heptioic acid.

Lactone C₆H₁₀O₅. [150°]. Obtained by decomposing a hot solution of the Ba salt with the theoretical quantity of H₂SO₄. Needles, *v. sol.* water, *m. sol.* alcohol, *insol.* ether.

Phenyl hydrazide C₁₂H₁₈N₂O₅. [220°–223°]. Formed by boiling the Ba salt with aqueous NaOH, and adding HOAc and phenyl hydrazine acetate (Fischer a. Passmore, *B.* 23, 2732). Very small prisms; *sol.* hot water. Decomposed on fusion.

MANTLE-MUCIN *v.* PROTEINS, *Appendix C.*

MARGARIC ACID C₁₇H₃₄O₂. (*Heptadecioic acid*). Mol. w. 270. [60°]. The name margaric acid was originally applied to an acid C₁₇H₃₄O₂ supposed to occur in the product of the saponification of solid natural fats; but this acid was shown by Heintz to be a mixture of palmitic acid C₁₆H₃₂O₂ and stearic acid C₁₈H₃₆O₂. An acid C₁₇H₃₄O₂ occurs, however, according to Ebert (*B.* 8, 775), in adipocere, a substance formed in dead tissues of animals. Formed by boiling its nitrile (cetyl cyanide) with alcoholic potash (Heintz *P.* 102, 272). White crystals.—BaA₂: white amorphous powder.—AgA: white amorphous powder.

Nitrile C₁₇H₃₃CN. [53°] (?) (Köhler, *J.* 1856 579; cf. Becker, *A.* 102, 213). According to Heintz (*J.* 1857, 445), margaritrile prepared from potassium cetyl sulphate and KCy is *ar. oil*.

Margaric acid C₁₇H₃₄CO₂H. [60° uncor.] (377° at 100 mm.). Prepared by the oxidation

of methyl-heptadecyl-ketone (Krafft, B. 12, 1672). Probably identical with the preceding acid.

MARJORAM OIL. S.G. 1.2-911 (Bruylants). The essential oil obtained by steam-distillation from the flowers of sweet marjoram (*Majorana hortensis* or *Origanum majorana*). Yellow oil which becomes brown on standing. It has a pungent smell, a hot peppery taste, and an acid reaction. According to Bruylants (*J. Ph.* [4] 30, 33; cf. Mulder, A. 31, 69) it begins to boil at 185° and the thermometer remains stationary at 215°-220°. Bruylants found it to consist of 5 p.c. of a dextrorotatory terpene, 85 p.c. of a mixture of dextrorotatory camphor and borneol, and 10 p.c. of resin. According to Kane (A. 32, 285) the essential oil of wild marjoram (*Origanum vulgare*) contains a terpene which boils at 161° and has S.G. .867. According to Beilstein and Wiegand (B. 15, 2855) oil of sweet marjoram contains a terpene $C_{15}H_{16}$ (178° i. V.). S.G. 1.2-846, which absorbs HCl, forming liquid $C_{15}H_{16}HCl$. By distilling the oil of marjoram over sodium Beilstein and Wiegand obtained liquid $C_{15}H_{16}O$ (200°-220°).

Cretan oil of marjoram from *Origanum hirtum* has S.G. 1.2-951, and 100 mm. produce a rotation of -0.4°. It contains 50 p.c. of carvacrol [2°] and dissolves in half its volume of 15 p.c. soda solution (Jahns, *Ar. Ph.* [3] 15, 1; 16, 277). The oil also contains a mixture of terpenes, and a phenol that is coloured violet by $FeCl_3$. Jahns found a little carvacrol in the oil from *Origanum vulgare*.

MARRUBIIN. [160°]. The bitter principle of white horehound (*Marrubium vulgare*) (Kromayer, *Ar. Ph.* [2] 108, 257; Harms, J. 1863, 593). Prepared by exhausting the dried herb with hot water, evaporating, and extracting with alcohol. Large tables (from ether) or needles (from alcohol). Almost insol. cold, sl. sol. hot, water. Not affected by alkalis. Metallic salts do not ppt. it. Not ppd. by tannin. Hot conc. $HClAq$ does not affect it. Conc. H_2SO_4 gives a brownish-yellow solution. Cold HNO_3 has no action; hot HNO_3 forms a yellow solution.

MARSH GAS v. METHANE.

MARTYLAMINE v. p-AMIDO-DIPHENYL.

MASOPIN $C_{22}H_{30}O$. [155°]. Occurs in a resin used in Mexico for chewing; said to be the dried juice of a tree called Dschlite. The resin occurs in porous lumps, smelling like rotten cheese, but with little taste. The masopin is obtained by boiling the resin with water, and crystallising the residue from alcohol (Genth, A. 46, 124). White silky needles (from ether). After fusion, it melts a second time at 70°. On distillation it yields a terpene and a crystalline acid, of which the Ag salt contains 45.5 p.c. of silver.

MASTIC. A resin obtained by incisions in the bark of *Pistacia lentiscus*, a tree growing in Chios. Small round transparent grains with faint agreeable odour. Used for making varnishes and, from the earliest times, for chewing. Softens when masticated. S.G. 1.074. Aqueous alcohol dissolves the greater part $C_{16}H_{22}O_4$, leaving mastioin $C_{16}H_{22}O_2$ undissolved (Johnston, P. T. 1839, 132). Flückiger (*Ar. Ph.* 219, 170) found 2 p.c. of a dextrorotatory terpene in mastic.

MATEZITE $C_{18}H_{26}O_8$. [187°]. $[a]_D = 64.7$. Occurs in Madagascar caoutchouc (mateza rorina) (Girard, *Bl.* [2] 21, 220; C. R. 110, 84). Identical with (B)-Pinite (Combes, C. R. 110, 46). Crystalline nodules, v. e. sol. water, m. sol. alcohol. Sublimes above 200°. Resembles damboite but is dextrorotatory. Fuming $HIAq$ splits it up on heating into MeI and matezo-dambos $C_{18}H_{26}O_8$ [246°] $[a]_D = 67.6$, which is dextrorotatory and more soluble in water than dambose. Matezo-dambos is identical with the (B)-inosite of Maquenne (C. R. 109, 812). It forms small tetrahedra when ppd. by adding alcohol to its aqueous solution.

MATICIN. A bitter substance which remains dissolved in the water in the retort in the preparation of the essential oil of matico by distilling the leaves of *Piper asperifolium* with steam. It is sol. water and alcohol, and insol. ether (Hodges, P. M. [3] 25, 204; C. S. Mem. 1, 123). Its solution is not ppd. by lead acetate.

MATICO-CAMPHOR $C_{15}H_{20}O$. [94°]. Occurs in the essential oil of matico-leaves (*Piper angustifolium*), from which it is obtained by distilling off the greater part and allowing the residue to crystallise (Kügler, B. 16, 2841). Hexagonal crystals. V. sol. alcohol, ether, benzene, petroleum-ether, &c. With HCl it gives a violet colour, passing into blue, and finally becoming green. H_2SO_4 colours it yellow, then red, and lastly violet. A mixture of H_2SO_4 and HNO_3 first produces a yellow, which then becomes violet, and finally a splendid blue.

MAUVANILINE $C_{16}H_{11}N_3$. A by-product in the preparation of rosaniline by the oxidation of crude aniline (De laire, Girard a. Chapoteaut, C. R. 64, 416; *Bl.* [2] 7, 366; cf. Girard a. Pabst, *Bl.* [2] 34, 37). Light-brown crystals (containing $\frac{1}{2} aq$), which is given off at 150° with decomposition. Insol. cold, v. sl. sol. hot, water, sl. alcohol, ether, and benzene. Its salts form lustrous bronze-green crystals, v. sl. sol. cold water, and dye silk and wool mallow-red. Tri-ethyl-mauvaniline $C_{16}H_{11}Et_3N_3$ dyes bluish-violet, while tri-phenyl-mauvaniline $C_{16}H_{11}Ph_3N_3$ is a blue dye.

MAUVEINE $C_{22}H_{21}N_3$. The first aniline dye introduced (Perkin, 1856). Obtained by adding a cold dilute solution of a salt of crude aniline to a cold dilute solution of $K_2Cr_2O_7$ and leaving the mixture to stand for 12 hours. The resulting black pp. is dried, extracted with benzene, dissolved in alcohol, and the filtrate evaporated. When aniline sulphate is used the product is $(C_{22}H_{21}N_3)_2SO_4$; aniline hydrochloride yields $C_{22}H_{21}N_3Cl$ (Perkin, A. 131, 200; C. J. 35, 717). On adding aqueous KOH to a solution of a salt of mauveine the base separates as a violet-black crystalline substance. It dissolves in alcohol, forming a violet solution, which on addition of acids turns purple. Mauveine is insol. benzene and ether. With dilute acids it forms purple solutions; with stronger acids, blue. Conc. H_2SO_4 forms a dirty-green solution. Dyes silk mauve. Used for postage stamps. Oxidised by PbO_2 and boiling HOAc it gives para-safranin $C_{20}H_{19}N_3$.

Salts.—B'HCl: tufts of small prisms with green metallic lustre. Insol. cold, sl. sol. hot, water, m. sol. alcohol, nearly insol. ether.—B'H $_2$ Cl $_2$: blue, with coppery lustre. Unstable. Becomes B'HCl when dissolved in alcohol.

$B'H_2PtCl_6$: green crystalline powder, v. sl. sol. alcohol.— $B'H_2PtCl_6$: blue.— $B'HAuCl_4$.— $B'HBBr$.— $B'HI$: lustrous prisms.— $B'H_2SO_4$.— $B'H_2CO_3$: prisms, with green metallic lustre. On boiling its solution CO_2 is given off.

* Ethyl-mauveine $C_{27}H_{28}EtN_4$. Formed by heating mauveine with EtI at 100° . Its colour is redder than that of mauveine. During the manufacture crystals of $C_{27}H_{28}EtN_4HI$, sometimes appear.— $C_{27}H_{28}EtN_4HCl$. Forms a reddish-purple solution in alcohol.— $(C_{27}H_{28}EtN_4HCl)_2PtCl_6$. Golden-green lustre.

Pseudo-mauveine $C_{27}H_{28}N_4$ (Perkin, *C. J.* 35, 725). Present in commercial mauveine. It is more soluble in alcohol than mauveine. It is a strong base, and dyes silk almost exactly like mauveine. Pure aniline gives pseudo-mauveine on oxidation, hence it does not contain methyl. Mauveine is probably derived from aniline and *p*-toluidine. The violet colouration given by bleaching-powder to a dilute solution of aniline is probably due to pseudo-mauveine.— $C_{27}H_{28}N_4HCl$. Greenish-golden lustre.— $(B'HC)_2PtCl_6$.

MAYER'S REAGENT v. ALKALOIDS, Reaction 8.

MAYNAS RESIN. *Calaba* or *Galba* of the Antilles (Lewy, *A. Ch.* [3] 10, 380). A resin extracted by incision from *Calophyllum calaba*. Alcohol extracts from it $C_{11}H_{16}O_4$, which separates on cooling in yellow monoclinic prisms. Maynas resin is insol. water, but v. sol. $KOHAq$ and ammonia. It melts about 105° .

MECCA BALSAM. *Balm of Gilead*. The produce of *Balsamodendron gileadense*, a shrub growing in Arabia Felix. There appear to be several varieties of it. It contains a fragrant volatile oil, an acid resin sol. alcohol, and a resin, insoluble in alcohol (Bonastre, *A. J.* 147; cf. Trommsdorff (*Trommsd. Neues Journal*, 16, 62).

MECONIC ACID $C_8H_6O_4$, 8aq, i.e. $C_8H_6O_4(OH)(CO_2H)_2$. Mol. w. 200. S. 25 at 100° . Heat of neutralisation (4 mols. $NaOH$) 37,882 (Gal a. Werner, *Bt.* [2] 47, 162). Electrical conductivity: Ostwald (*J. pr.* [2] 32, 368).

Occurrence.—In opium (Sertürner, *Am. S.* 55, 72; 57, 183; 64, 65; Robiquet, *A. Ch.* 5, 282; 51, 236; 53, 425; Liebig, *A. J.* 7, 87; 26, 118, 147).

Preparation.—Opium is exhausted with water at 38° ; the extract is neutralised with $CaCO_3$, evaporated to a syrup, and mixed with a concentrated solution of $CaCl_2$, which ppt. calcium meconate. The pp. (1 pt.) is suspended in conc. $HClAq$ (3 pts.) mixed with boiling water (20 pts.), and kept near 100° till dissolved. On cooling, acid calcium meconate separates in crystals. These (1 pt.) are again dissolved in a mixture of $HClAq$ (3 pts.) and boiling water (20 pts.), and, on cooling, meconic acid separates (Gregory, *A. J.* 24, 48). It may be further purified by crystallising its ammonium salt from water (How, *A. J.* 88, 850).

Properties.—Micaceous scales or small trimetric prisms (containing 8aq) (Burghardt, *C. J.* 27, 987). It gives off its water of crystallisation at 100° , then becoming a white opaque mass. Has a sour taste and strongly reddens litmus. Sl. sol. cold water, v. sol. alcohol, sl. sol. ether. $FeCl_3$ colours its solutions blood-red. This colouration, like that with sulphocyanides, is

much weakened by oxalic acid and by metaphosphoric acid (Dupré, *C. N.* 32, 15), but it is not destroyed by boiling or by dilute $HClAq$. Meconic acid may be regarded as a derivative of the hypothetical $CH \begin{smallmatrix} \text{CH:OH} \\ \text{OH:CH} \end{smallmatrix} > O$.

Reactions.—1. Heated at 120° it gives off CO_2 , and comenic acid $C_8H_6O_4(OH)(CO_2H)$ remains. At a higher temperature the comenic acid is further resolved, partly into CO_2 , and pyromecenic acid $C_8H_6O_4(OH)$, and partly into water, acetic acid, and oily and carbonaceous products. 2. When boiled with water or with $HClAq$ it gives CO_2 and comenic acid.—3. Nitric acid oxidises it, forming oxalic acid.—4. Boiling conc. $KOHAq$ also yields oxalic acid.—5. Boiling aqueous ammonia forms comenamic acid $C_8H_6NO(OH)CO_2H$. Comenamic acid yields pyridine on dry distillation with zinc-dust (Lieben a. Haitinger, *B.* 16, 1263). The comenamic acid is di-oxy-picolinic acid, and comenic acid is probably an intermediate product in its formation.—6. Bromine, acting on its aqueous solution, forms a brominated comenic acid.—7. Aqueous HI gives comenic acid.—8. Sodium-amalgam reduces it to hydro-mecenic acid.—9. Gives with alcohol and HCl a di-ethyl ether, $C_8H_6O_4(OH)(CO_2Et)_2$, whence a silver compound, $C_8H_6O_4(OAg)(CO_2Et)_2$, which gives with EtI a tri-ethyl derivative $C_8H_6O_4(OEt)(CO_2Et)_3$. [61°]. This gives no colour with $FeCl_3$ (Öst a. Mennel, *J. pr.* [2] 23, 439).—10. PCl_5 converts it into a liquid chloride, probably $C_8H_6Cl_6(COCl)_2$, whence ice-water forms 'chloro-mecenic' acid, $C_8Cl_6O(OH)(CO_2H)$, aq [165°], whereas warm water forms only oxalic acid (Hilsebein, *J. pr.* [2] 82, 186). Chloro-mecenic acid gives a green colour, with solution of ferric chloride. It forms an ether, $C_8Cl_6O(OH)(CO_2H)(CO_2Et)$, [148°], which gives an acetyl derivative $C_8Cl_6O(OAc)(CO_2H)(CO_2Et)$, [70°]. It also forms barium salts. Chloro-mecenic acid is decomposed by sublimation into carbonic acid and yellowish needles of pyro-chloro-mecenic acid, $C_8H_6Cl_6O(OH)$, aq [174°]. The solution of this acid is turned dark-green by $FeCl_3$. Its alcoholic solution turns the skin red. It forms a crystalline calcium salt, $(C_8H_6Cl_6O)_2Ca$. Chloro-mecenic acid dissolves in conc. NH_3 , the solution turning successively red, violet, and blue, owing to the formation of two nitrogenous colouring matters, 'mecenic blue' and 'mecenic red'. Chloro-mecenic acid is reduced by treatment with sodium amalgam, forming di-hydro-chloro-mecenic acid $C_8H_8Cl_6O(OH)(CO_2H)_2$, [145°]. Fuming HI at 100° reduces chloro-mecenic acid to an oxy-pentane di-carboxylic acid, $C_8H_8O_2(CO_2H)_2$. This body forms groups of needles [149°]. Its silver salt, Ag_2A'' , is a crystalline powder, insol. water. Its barium salt, Ba_2A'' , forms white prisms. Its ether, Et_2A'' , is an oil, boiling about (250°) . Oxy-pentane di-carboxylic acid, when distilled with lime, yields amyl alcohol, (c. 180°) (Hilsebein, *J. pr.* [2] 82, 129–158).

Salts.— $(NH_4)_2H_2A''$ aq; granular crystals, sl. sol. water.— $(NH_4)_2HA''$ aq; slender needles.—A barium salt is ppd. by adding $BaCl_2$ to a solution of an alkaline meconate, in white flakes, soluble in acetic acid.— CaH_2A'' , 2aq; ppd. by adding $CaCl_2$ to aqueous meconic acid.— $CaHA''$ aq; yellow gelatinous pp., formed by

adding CaCl_2 to a solution of ammonium meconate.—The cupric salts are green pps.— PbA'' 2aq: white flocks, ppd. by adding lead acetate to a solution of meconic acid (Stenhouse, *A.* 51, 281).—A sparingly soluble ferric salt may be obtained by the action of ferric sulphate on ammonium meconate (Stenhouse).— $\text{Fe}_2\text{CaA}''$, 6aq (Rennie, *C. N.* 42, 75).— $\text{Ag}_2\text{HA}'''$: white pp. got by adding AgNO_3 to a solution of meconic acid.— $\text{Ag}_2\text{A}'''$: yellow pp. from ammonium meconate and AgNO_3 .—Aniline salt: $(\text{C}_6\text{H}_5\text{NH}_2)_2\text{C}_2\text{H}_2\text{O}_4$: crystalline (Korff, *A.* 138, 195).—Urea salt: $(\text{CON}_2\text{H}_4)_2\text{C}_2\text{H}_2\text{O}_4$ (Hlasiwetz, *J.* 1856, 699).—Narceine salt [126°]: from narceine (1 mol.) and meconic acid (1 mol.). Lemon-yellow crystals, sol. hot water (Merck, *O. C.* 1889, 884).—The acid morphine salt could not be obtained by Dott [*Ph.* [3] 17, 690]. It will be observed that meconic acid has but little tendency to form tribasic salts, so that it might perhaps be more correctly regarded as a dibasic acid (cf. Dittmar & Dewar, *Pr. E.* 1867; Dott, *Ph.* [3] 11, 576).

Ethyl derivative $\text{C}_2\text{H}_5(\text{CO}_2\text{H})_2(\text{OEt})$. [200°]. Formed by boiling $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})_2(\text{OEt})$ for forty-eight hours with water, and evaporating the solution. Small prisms grouped in lumps. Decomposed by fusion. Gives no colour with FeCl_3 . Gives, with most metallic salts, no pp. Lead acetate is an exception. Heated alone till it melts, CO_2 is given off, and the ethyl derivative of comenic acid formed. Its aqueous solution is converted by bromine into a brominated derivative of comenic ether.— PbA'' 1½aq. Crystalline pp.

Mono-ethyl ether $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})(\text{CO}_2\text{H})(\text{OH})$. [179°]. Prepared by dissolving meconic acid in alcohol, heating to 100°, and subjecting to a current of HCl till crystals begin to appear. The liquid on cooling deposits crystals of the mono-ethyl ether (E. Mennel, *J. pr.* [2] 26, 450). It gives a red colour with FeCl_3 .—Silver salt $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})(\text{CO}_2\text{Ag})(\text{OH})_2$ aq.—Barium salts $\text{BaC}_2\text{H}_5\text{O}_4$ and $\text{Ba}(\text{C}_2\text{H}_5\text{O}_4)_2$.

Di-ethyl ether $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})_2(\text{OH})$. [112°]. Prepared by passing HCl into an alcoholic solution at 100° until the crystals (of mono-ethyl ether) which are first formed are dissolved up again. On pouring into water, plates of the di-ethyl ether separate (How, *A.* 83, 350; Mennel, *J. pr.* [2] 26, 453). Plates. From dilute solutions it crystallises with ½aq as needles. Gives a red colour with FeCl_3 . An amorphous pp. is formed by adding AgNO_3 and then exactly neutralising with NH_3 .— $\text{NH}_4\text{C}_2\text{H}_5\text{O}_4$: needles (from alcohol), v. sol. water. Its solution is ppd. by various metallic salts.

Ethyl derivative of the diethyl ether $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})_2(\text{OEt})$. [61°]. From $\text{C}_2\text{H}_5(\text{CO}_2\text{Et})_2(\text{OAg})$ and EtI . Gives no red colour with FeCl_3 . Boiled with water it changes to the ethyl derivative of meconic acid (*q. v.*). Not acted upon by bromine.

Mono-amide $\text{C}_2\text{H}_5(\text{CONH}_2)(\text{CO}_2\text{H})(\text{OH})$ aq. *Meconamic acid*. From the above by the action of aqueous NH_3 followed by HCl . Crystallises in hard lumps from water. Not decomposed by cold NaOH , converted by boiling NaOH into meconate. Copper salt $\text{C}_2\text{H}_5\text{O}_4\text{Cu}$ 2aq.

Basic ammonium salt of amide $\text{C}_2\text{H}_5(\text{CONH}_2)(\text{CO}_2\text{NH}_2)(\text{ONH}_2)$. This yellow pp. is the first product of the action of NH_3 upon mono-ethyl meconate.

Di-amide $\text{C}_2\text{H}_5(\text{OH})(\text{CONH}_2)_2$. From the diethyl ether and boiling aqueous NH_3 (How). Powder, sl. sol. cold water.

Oxim $\text{C}_2\text{H}_5\text{O}_4\text{NH}$. Formed by treating meconic acid with hydroxylamine hydrochloride (Oderheimer, *B.* 17, 2081). Small colourless needles (containing H_2O). V. sol. water, sl. sol. alcohol, ether, and chloroform, insol. ligroine. Decomposes suddenly at 190°. It gives a red colour with Fe_2Cl_6 . It reduces Fehling's solution. By boiling with HCl hydroxylamine is split off.— $\text{A}''\text{Na}$: colourless crystals.— $\text{A}''\text{Ag}$ aq: white sparingly soluble pp.— $\text{A}''\text{Ba}$ 10aq: sparingly soluble concentric needles.— $\text{A}''\text{Ca}$ 2aq: sparingly soluble needles.

Hexahydrate $\text{C}_2\text{H}_5\text{O}_4$. *Hydromeconic acid*. Obtained by reducing meconic acid suspended in water by adding sodium amalgam (Korff, *A.* 138, 191). Separated by decomposing the lead salt by H_2S and evaporating the filtrate. Strongly acid syrup, v. sol. water, m. sol. alcohol, insol. ether. Ppd. as deliquescent flocks on adding ether to its alcoholic solution. Not affected by HI . Gives no colour with FeCl_3 .— BaA'' 2aq: amorphous pp.; sol. water, insol. alcohol.— PbA'' 1½aq: amorphous pp.— $\text{Ag}_2\text{A}''$ ½aq: white granular pp.

Reference.—PYROMECONIC ACID and PYROMECONAZONIC ACID.

MECONIDINE $\text{C}_{21}\text{H}_{23}\text{NO}_4$. [58°]. An alkaloid contained in the aqueous extract of opium (Hesse, *A.* 153, 47). The aqueous extract is ppd. by Na_2CO_3 ; the pp. dissolved in ether, the ethereal solution shaken with dilute acetic acid, and the acid solution poured into aqueous NaOH . After 24 hours the pp. of thebain and papaverine is removed by filtration, the filtrate neutralised by HCl , rendered alkaline by NH_3 , and shaken with chloroform. The chloroform is then shaken with acetic acid; and the acid solution exactly neutralised by ammonia, which ppts. lanthopine. The filtrate is mixed with KOH and shaken with ether. Codanine and laudanine separate, and the mother-liquor is then shaken with dilute acetic acid, the solution saturated with NaCl , the ppd. meconidine hydrochloride decomposed by NaHCO_3 , and the base extracted with ether and dried at 90°.

Properties.—Brownish-yellow transparent amorphous mass. Cannot be sublimed. Tasteless. Insol. water, v. sol. alcohol, ether, benzene, chloroform, and acetone. Its alcoholic solution turns red litmus blue. Sl. sol. NH_3 aq, v. sol. NaOHAq . Can be extracted by ether from its solution in ammonia but not from that in caustic soda. Its solution in dilute H_2SO_4 becomes rose-coloured in a few minutes, and purple-red on standing for some time, or immediately on boiling. Conc. H_2SO_4 gives an orange-green solution. Conc. HNO_3 colours it orange-red. The dilute solutions of the salts have an intensely bitter taste.— $\text{B}''\text{H}_2\text{PtCl}_6$: yellow amorphous pp. which soon turns reddish. The aurochloride is a dingy yellow amorphous pp.

MECONIN $\text{C}_{10}\text{H}_{10}\text{O}_4$ i.e.

$\text{C}_2\text{H}_5(\text{OMe})_2\text{C}(\text{CO})_2\text{O}$. [1:6:2]? *Anhydride of*

Meconinic acid. *Opianyl*. Mol. w. 194. [99°] (M. a. F.); [102.5°] (Vogelscheider, M. 3, 351; Prinz, J. pr. [2] 24, 371). S. 4 in the cold; 6 at 100°. A neutral substance existing in opium (Dublanc, A. Ch. [2] 49, 17; Couerbe, A. Ch. 49, 11; 60, 337; 59, 148). It may also be extracted by ether from the root of *Hydrastis canadensis* (Freund, B. 22, 459).

Formation.—1. Together with cotarnine, opianic acid, and hemipic acid, by the action of warm dilute nitric acid on narcotine (Anderson, Tr. E. 20, 347; 21, 204).—2. From opianic acid by the action of sodium-amalgam, or of zinc and H_2SO_4 (Matthiessen a. Foster, C. J. 16, 349).—3. Together with hemipic acid by the action of caustic alkalis on opianic acid (M. a. F.).

Preparation.—1. A concentrated aqueous extract of opium is ppd. by dilute ammonia, and the filtrate evaporated to crystallisation. The crystals are extracted with alcohol, which after evaporation deposits crystals of meconin, which are recrystallised from water and ether successively (Couerbe).—2. The aqueous extract of opium is precipitated by chloride of calcium; the precipitated meconate of calcium is filtered; the filtrate evaporated to the crystallising point, and separated from the deposited hydrochloride of morphine; and the dark mother-liquor is diluted with water, filtered from the flocks which separate, and treated with ammonia, which precipitates narcotins, thebaine, and a large quantity of resin. The filtrate is mixed with acetate of lead; the excess of lead is removed from the filtered liquid by dilute sulphuric acid; and the filtrate is neutralised with ammonia, and evaporated to the crystallising point at a moderate heat, whereupon narcotine separates out, and then sal-ammoniac by further concentration. The mother-liquor is repeatedly digested with $\frac{1}{2}$ vol. ether at 26°, and the ether is distilled off from the extracts, a brown syrup then remaining. On treating this syrup with dilute hydrochloric acid, papaverine dissolves, and meconin remains in the form of a dark-grey crystalline powder, which, to free it from resin and purify it completely, must be several times crystallised from boiling water, with addition of animal charcoal (Anderson).

Properties.—Colourless hexagonal prisms. Appears tasteless at first, but afterwards acid. May be sublimed. Sl. sol. cold water, m. sol. alcohol and ether. Sol. KOHAq, nearly insol. NH₄Aq. Inactive. Its aqueous solution ppts. lead subacetate but not lead acetate. Dilute H_2SO_4 forms a colourless solution which becomes dark green when evaporated (Couerbe). Conc. H_2SO_4 forms a colourless solution which becomes purple on heating.

Reactions.—1. Conc. HClAq at 100° gives MeCl and methyl-normeconin $C_8H_8O_4$ (M. a. F.). HI acts in like manner.—2. *Baryta-water* dissolves meconin forming 'barium meconinate'. $(C_8H_7(OMe)_2(CH_2OH).CO)_2Ba$. This salt crystallises in needles, but the free acid splits up at once into water and its anhydride meconin (Hessert, B. 11, 240; Prinz, J. pr. [2] 24, 373).—3. *Potash-fusion* forms methyl-normeconin $C_8H_8O_4$ [125°] and, finally, protocatechuic acid. 4. Oxidised by MnO_2 and dilute H_2SO_4 to opianic acid.—5. $KMnO_4$ oxidises it to hemipic acid [180°].

Chloro-meconin $C_8H_7ClO_4$. [175°]. Obtained by passing chlorine into a cold saturated aqueous solution of meconin (Anderson, A. 98, 47). Colourless needles. May be sublimed? Sl. sol. cold water, v. sol. alcohol and ether. Hot H_2SO_4 gives a greenish-blue colour.

Bromo-meconin $C_8H_7BrO_4$. [167°] (Anderson); [177°] (Salomon, B. 20, 888). From meconin and bromine-water. Colourless needles, sl. sol. water.

Iodo-meconin $C_8H_7IO_4$. [112°]. From meconin and chloride of iodine (A.). Needles, nearly insol. water, m. sol. alcohol and ether.

Nitro-meconin $C_8H_7(NO_2)O_4$. [158°]. From meconin and HNO_3 . White needles (from alcohol).

Amido-meconin $C_8H_7(NH_2)O_4$. [171°]. Obtained by reducing nitro-meconin with iron and acetic acid (S.). M. sol. hot benzene.

Methyl-normeconin $C_8H_8O_4$, i.e.

$C_8H_7(OH)(OMe) \begin{matrix} < \\ CO \end{matrix} > O$. [125°]. Obtained by heating meconin with conc. HClAq (Matthiessen a. Foster); by heating meconin with KCy at 180° (Bowman, B. 20, 890); or by potash-fusion from meconin or narcotine (Beckett a. Wright, J. 1876, 810). Monoclinic prisms; v. sol. hot water and alcohol, sl. sol. ether. $FeCl_3$ colours it blue. It reduces silver salts in the cold. Potash-fusion converts it into protocatechuic acid.— $CaA'_{1/2}$ — $BaA'_{1/2}$.

Meconin-acetic acid $C_{12}H_{12}O_6$, i.e.

$C_8H_7(OMe)_2 \begin{matrix} < \\ CO \\ > \\ CH_2CH_2CO_2H \end{matrix} > O$. [167°]. Obtained by heating opianic acid with a mixture of malonic acid, acetic acid, and sodium acetate for 10 hours at 100° (Liebermann a. Kleemann, B. 19, 2290). Glistening needles. By boiling with baryta-water it is converted into opianyl-acetic acid $C_8H_7(OMe)(CO_2H).CH(OH).CH_2CO_2H$. By heating with HCl it is dimethylated, giving $C_8H_7(OH) \begin{matrix} < \\ CO \\ > \\ CH_2CH_2CO_2H \end{matrix} > O$ [228°], of which the ethyl ether melts at 131°.

Salts.— $A'Ag$: white slightly soluble crystals. — $A'Ca$: needles, sl. sol. water. — $A'Cu$: blue crystalline pp.

Methyl ether $A'Me$: [124°]; glistening plates.

Ethyl ether $A'Et$: [83°]; plates, sol. alcohol, ether, and hot water.

Nitro-meconin acetic acid

$C_8H(NO_2)(OMe)_2 \begin{matrix} < \\ CO \\ > \\ CH_2CH_2CO_2H \end{matrix} > O$. [176°]. Nearly colourless crystals. Obtained by nitration of meconin-acetic acid. It dissolves in cold H_2SO_4 with a yellow colour, which becomes red on warming from formation of an indigo derivative. By tin and HCl it is reduced to the lactone of (Py. 1:3)-di-oxy-(B. 2:3)-di-methoxy-di-hydroquinoline-(B. 1)-carboxylic acid

$C_8H(OMe)_2 \begin{matrix} < \\ CO \\ > \\ CH_2CH_2 \\ | \\ NHCO \end{matrix} > O$. [256°].

Salts.— $A'Ca$: yellow needles.— $A'Ag$: curdy pp.— $A'Cu$: green pp.

Ethy ether AEt: $[\alpha]_D^{20}$; glistening needles; insol. water, sol. alcohol and benzene (Liebmann, A. Kleemann, B. 19, 2295).

ψ -Meconin $C_8H_7(OMe)_2 \cdot \frac{CH_3}{CO} > O$ $[1:6:3]$?

Di-methyl derivative of di-oxy-phthalide. $[124^\circ]$. When hemipimide, the imide of hemipic acid $C_8H_7(OMe)_2 \cdot \frac{CO}{CO} > NH$, is heated with tin and hydrochloric acid it is reduced to hemipimidine $C_8H_7(OMe)_2 \cdot \frac{CH_3}{CO} > NH$ $[181^\circ]$, which yields a

nitroso-derivative $C_8H_7(OMe)_2 \cdot \frac{CH_3}{CO} > N.NO$ $[156^\circ]$, which on treatment with dilute NaOH in the cold yields pseudo-meconin (Salomon, B. 20, 883). Obtained also by boiling hemipimide with zinc-dust and acetic acid. Long colourless needles (from water). Sl. sol. cold water, sol. benzene, alcohol, and ether. Unlike meconin it is not affected by boiling with dilute H_2SO_4 and MnO_2 . Dilute HNO_3 at 150° forms nitro-hemipic acid and nitro- ψ -meconin, whereas meconin yields only nitro-meconin. Fusion with KOH or KCy does not affect ψ -meconin.

Bromo- ψ -meconin $C_{10}H_7BrO_2$. $[142^\circ]$. From ψ -meconin and bromine. White flocculent pp., sol. benzene, insol. petroleum.

Nitro- ψ -meconin $C_{10}H_7(NO_2)O_2$. $[166^\circ]$. From ψ -meconin and fuming HNO_3 . Yellow needles, which yield oxalic acid on further treatment with nitric acid.

Amido- ψ -meconin $C_{10}H_7(NH_2)O_2$. $[165^\circ]$. Obtained by reducing the preceding. More basic than amido-meconin.

MECONISIN $C_8H_7O_2$. $[88^\circ]$. S. 8-7. Occurs in opium, and found in the mother-liquor after separation of meconin. When this is allowed to stand, crystals are deposited, which are washed with alcohol and recrystallised from water (T. a. H. Smith, Ph. [3] 8, 981). Large, leaf-shaped crystals; v. e. sol. hot water. It gives a green colour when heated with dilute H_2SO_4 .

MEDULLIC ACID $C_{21}H_{42}O_2$. $[72.5^\circ]$. A fatty acid said to be produced, together with stearic and palmitic acids, by the saponification of beef-marrow (Eylerts, Ar. Ph. [2] 104, 129).

MELAM v. CYANIC ACIDS.

MELAMINE v. Cyanuramide in the article CYANIC ACIDS.

MELAMPYRITE v. DULCITE.

MELANILINE v. DI-PHENYL-GUANIDINE.

MELANIN. C 60; H 4.8; N 10.8; ash 2.7. A black pigment covering the choroid membrane of the eye (Scherer, A. 40, 63). Insol. water, alcohol, and ether.

Phymatorhusin. C 55.7; H 6.0; N 12.3; S 8 to 9; Fe .07 to .2. A pigment occurring in melanotic urine and tumours. It is obtained by ppg. with baryta, dissolving in Na_2CO_3 , and ppg. with dilute H_2SO_4 (Berdez a. Nencki, J. Th. 1886, 477; Mörmner, H. 11, 81). It is a brownish-black amorphous powder, insol. water, alcohol, ether, chloroform, and dilute mineral acids; v. e. sol. ammonia, aqueous NaOH, Na_2HPO_4 , and Na_2CO_3 . Ppd. from its solution in NaOH by baryta, $MgSO_4$, and $BaCl_2$. With potash-fusion, it gives skatole, volatile fatty acids, nitriles, KCy, and K_2S . Hot H_2SO_4 forms pyridine. Phymatorhusin is accompanied by another black substance, which differs from it in being soluble

in 50-75 p.c. acetic acid. It contains 5.9 p.c. of sulphur and .2 p.c. Fe.

Hippomelanin. C 53.5-55.6; H 2.7-3.9; N 10.5-10.9; S 2.8-3.0. Occurs in melanotic tumours of horses. May be obtained by diluting the emulsion of a melanotic spleen with water and adding $CaCl_2$ and Na_2HPO_4 . The pp. is washed at 40° , and then treated with a digestive fluid until the solution ceases to give a reaction for peptones. The residue is washed with aqueous soda, alcohol and ether (Mura, C. C. 1887, 250). Brownish-black powder; insol. water, alcohol, and ether. Dissolves on warming in dilute acids and alkalis. Potash-fusion gives KCy, succinic acid, formic acid, and hippomelanin acid. Hippomelanin acid is a black amorphous body, sol. ammonia, and reppd. by HCl. It contains less S and more C than the melanin (Nencki a. Sieber, C. C. 1888, 587). The black pigment in dark hair and in bird's feathers after purifying by alcoholic NH_3 and dilute H_2SO_4 may be represented by the formula $C_{11}H_7N_3O_8$ (Hodgkinson a. Sorby, J. 1876, 936). Black powder. Not affected by dilute acids and alkalis.

Sepiatic acid. C 56.3; H 3.6; N 12.3; S .5; O 27.2. Obtained by digesting the pigment from the ink-bag of *sepia* with 15 pts. of 10 p.c. potash. Sol. alkalis; ppd. from ammoniacal solution by ammonia-zinc chloride or copper sulphate (Nencki a. Sieber).

MELANTHIN $C_{20}H_{13}O_5$. $[205^\circ]$. Occurs in the seeds of *Nigella sativa* (Greenish, Ph. [3] 10, 909, 1013). Prepared by extracting the seeds with alcohol, evaporating the extract, dissolving the pp. in alcohol, and fractionally ppg. with water. Minute grey crystals (from alcohol). Insol. water, benzene, CS_2 , and light petroleum; v. sol. alcohol, sol. alkalis, sl. sol. chloroform. Conc. H_2SO_4 gives a red colouration. H_2SO_4 and sugar give a violet-blue colour. Boiling dilute HCl splits it up into a sugar and melanthinigenin $C_{12}H_{13}O_5$, which forms minute crystals, sl. sol. water.

MELANURENIC ACID v. AMMELEIDE.

MELEM v. CYANIC ACIDS.

MELENE $C_{30}H_{40}$. $[62^\circ]$. (370°-380°). S.G. .89. V.D. 10-11.8. S. (alcohol) .13 in the cold; 3.6 at 78° . An olefine (?) produced by the dry distillation of bees-wax (Etting, A. 2, 252; Lowy, A. Ch. [3] 5, 395; Brodie, A. 71, 156).—White nacreous plates (from ether). Insol. water, sl. sol. cold alcohol, v. sol. ether. Not attacked by cold H_2SO_4 ; slightly attacked by boiling HNO_3 . Attacked by chlorine.

MELEZITOSE $C_{12}H_{22}O_{11}$. $[148^\circ]$. $[\alpha]_D = +94^\circ$ (B.); 88.5° (V.). A sugar discovered by Bonastre in the manna of Briancón which exudes from the young branches of 'mélèze' (*Pinus Larix*) (Berthelot, A. Ch. [3] 55, 282). It occurs also in 'taranjoline' or Turkestan manna (Villiers, Bl. [2] 27, 98; Alekhine, Bl. [2] 46, 824). Obtained by extracting the Briancón manna with boiling alcohol, and evaporating. After a few weeks melezitose separates; it is then recrystallised from alcohol. Monoclinic crystals containing aq (V.), or anhydrous crystals (A.). About as sweet as glucose. Dextrorotatory. V. sol. water, nearly insol. cold, sl. sol. boiling, alcohol, insol. ether. Its aqueous solution is ppd. by ammoniacal lead acetate. Boiling dilute H_2SO_4 forms glucose. It is turned brown by alkalis.

It does not reduce Fehling's solution. Does not ferment with yeast. It forms a compound with phenyl hydrazine. It gives an octo-acetyl derivative.

MELIHO-ACETIC ACID $C_8H_7N_2O_2$, i.e. $(CN)_2N_2H_2CH_2CO_2H$. Formed by treating cyanamide with chloro-acetic ether and NaOEt (Drechsel, *J. pr.* [2] 11, 332). Amorphous mass, but obtained in a crystalline state by ppg, its ammonium salt with HCl. Decomposed by heat without previous fusion. Insol. alcohol and ether, v. sl. sol. cold water. Sol. aqueous HClAq, baryta, and KOHAq, but insol. NH_4 Aq. — HA/HCl : needles, sl. sol. cold water. — HA/HNO_3 Aq. — AgA/HNO_3 Aq. — $(HA)_2H_2SO_4$ 4aq. **MELILOTIC ACID** v. OXY-PHENYL-PROPIONIC ACID.

MELILOTOL $C_{10}H_7O_2$ (?). An oil found, together with coumarin, in the yellow melilot (*Melilotus officinalis*). Extracted by distilling the plant, when in flower, with steam, and extracting the distillate with ether (Phipson, *C. N.* 32, 25; *C. R.* 86, 830). Liquid, v. sl. sol. water, alcohol, and ether. Has an agreeable odour. When boiled with conc. KOHAq it yields oxy-phenyl-propionic (meliotic) acid $C_8H_7O_3$. Melilotol is perhaps identical with the lactone of

MELINOIN - TRI - SULPHONIC ACID $C_8H_5O_6(SO_3H)_3$.

Formation.—1. By warming a mixture of *p*-oxy-benzoic-aldehyde, (β)-naphthol, and H_2SO_4 . 2. From benzoic-aldehyde, (β)-naphthol, and H_2SO_4 .—3. By heating Baeyer's condensation product $C_{10}H_7O_2$ (from benzoic-aldehyde and (β)-naphthol) with H_2SO_4 (Trzcinski, *B.* 16, 2335; 17, 500).—Yellow crystalline powder. Insol. absolute alcohol, tolerably sol. water, the dilute solution being of a rose-red colour with a green fluorescence. It dissolves in strong H_2SO_4 or HNO_3 with a splendid green fluorescence, and is not attacked even on boiling. It forms unstable compounds with HCl and H_2SO_4 , although it is itself a strong acid.

Salts.— $A''K_3$: easily soluble fine colourless needles.— $A''Ca_2$ aq: colourless soluble crystals.— $A''Ba_2$: sparingly soluble white amorphous pp. or microscopic needles.

MELISSIC ACID $C_{20}H_{30}O_2$, i.e. $C_{10}H_{19}CO_2H$, or $C_{11}H_{22}O_2$, i.e. $C_{10}H_{21}CO_2H$. [90°]. Occurs in bees'-wax (Natzger, *A.* 224, 225). Formed by heating the myricyl alcohol of bees'-wax with soda-lime at 270°–300° in absence of air (Brodie, *A.* 71, 156; Von Pieverling, *A.* 183, 344; Stürcke, *A.* 223, 295; Schwalb, *A.* 235, 106). Silky scales, composed of minute needles. Sol. alcohol, light petroleum, chloroform, and CS_2 , sl. sol. ether. According to Schalfeff (*B.* 12, 697) melissic acid is a mixture of acids.

Salts.— PbA' . [119°]. Insol. alcohol and ether, sl. sol. boiling toluene, chloroform, and glacial acetic acid. — MgA' . — CuA' . — $\Delta gA'$: [95°]; anhydrous pp.

Methyl ether MeA' . [71°]. Needles (from ligroin).

Ethyl ether EtA' . [70°] (Schwalb); [73°] (P.). Needles (from alcohol). Split up on heating into ethylene and the free acid.

Isocamyl ether $C_8H_{11}A'$. [69°].

MELISSYL ALCOHOL v. MYRICYL-ALCOHOL. **MELITOSE** v. RAFFINOSE and SUGARS.

MELLITIC ACID $C_6H_2O_7$, i.e. $C_6(CO_2H)_3$, *Mellitic acid*. Benzene (para-carboxylic acid). Mol. w. 842. H.C.v. 790,800. H.C.p. 788,200. H.F. 546,800 (Stohmann, Kleber, a. Langbein, *J. pr.* [2] 40, 141). Heat of neutralisation: 84,034 (Gal a. Werner, *Bl.* [2] 47, 162).

Occurrence.—As aluminium mellitate in honey-stone or mellite (Klaproth, *A. D.* 1799; Baeyer, *A. Suppl.* 6, 1).

Formation.—1. By the oxidation of hexamethyl-benzene by cold alkaline $KMnO_4$ (Friedel a. Crafts, *A. Ch.* [6] 1, 470).—2. By the oxidation of charcoal by $KMnO_4$ (Schulze, *B.* 4, 802, 806).—3. By the electrolysis of acidified water or of KOH using a positive electrode of gas carbon (Bartoli a. Papasogli, *G.* 11, 468; *O. C.* 1881, 827).—4. In very small quantity by oxidising coal, animal charcoal, or lampblack by alkaline NaOCl (Bartoli a. Papasogli, *G.* 15, 446).

Preparation.—Powdered honey-stone is boiled with ammonium carbonate, ammonia is added, and the filtrate evaporated to crystallisation. The ammonium mellitate is recrystallised with addition of a little ammonia, dissolved in water, ppd. by lead acetate, and the pp. decomposed by H_2S (Wöhler, *A.* 37, 263; Schwarz, *A.* 66, 47; Claus, *B.* 10, 559).

Properties.—Stellate groups of delicate silky needles (from alcohol); v. sol. water and alcohol. Decomposed by heat into CO_2 and pyromellitic acid $C_4H_2O_6$ (Erdmann, *J. pr.* 52, 432), which solidifies in the neck of the retort as a radio-crystalline mass. When strongly heated with glycerin it yields CO_2 and trimosic acid $C_8H_6O_9$. When heated to redness with soda-lime it yields benzene (Baeyer, *A. Suppl.* 7, 5). Not decomposed by boiling HNO_3 , sulphuric acid, $HIAq$, chlorine, or bromine. When its aqueous solution is electrolysed, CO_2 , hydrogen, CO , and oxygen are given off (Bangs, *J. R.* 12, 421).

Salts.— $(NH_4)_2C_6H_2O_7$ 3aq: trimetric crystals (Schwarz, *A.* 66, 47). Decomposed at 150° with formation of paramide and ammonium euchroate.— $(NH_4)_2H_2C_6H_2O_7$ 4aq: trimetric prisms. From ammonio-cupric mellitate and H_2S .— K_2A^{VI} 9aq: trimetric crystals.— $K_2H_2A^{VI}$ 8aq.— $K_2H_2A^{VI}$ 6aq: large prisms, more soluble in water than the normal potassium salt.— $(K_2H_2A^{VI})_2(KNO_3)_2$ 9aq (?).— Na_2A^{VI} 12aq: needles (from a hot conc. solution).— Na_2A^{VI} 18aq: large striated triclinic crystals.— Ba_2A^{VI} 3aq: white gelatinous pp., changing to scales.— Mg_2A^{VI} 18aq: crystalline mass.— $Mg_2(NH_4)_2A^{VI}$ 15aq: large glassy prisms.— Zn_2A^{VI} 15aq.— Zn_2A^{VI} 9aq.— Mn_2A^{VI} 18aq: minute needles, more sol. cold than hot water. S . (hot water) 125.— Co_2A^{VI} 18aq: minute prisms (from boiling water).— Ni_2A^{VI} 24aq: v. sl. sol. water.— Al_2A^{VI} 18aq. *Mellite*. S.G. 1.6. S.H. 336 (Bartoli, *G.* 14, 105). Occurs in lignite at Asten in Thuringia, Bilin in Bohemia, and near Walchau in Moravia. Massive nodules. Dimetric crystals: $a:c = 1:745$.— $Fe_2A^{VI}Fe_2O_9$ 9aq: minute lemon-yellow crystals, v. sl. sol. water.— Cu_2A^{VI} 12aq. From boiling mellitic acid and cupric acetate. Amorphous pp., becoming crystalline.— $Cu_2H_2A^{VI}$ 12aq.— $Cu_2(NH_4)_2A^{VI}$ 12aq: from cupric sulphate and ammonium mellitate.— Hg_2A^{VI} 6aq (dried at 100°); granular mass.—

$\text{I}_2\text{A}^{\text{vi}}$ 6aq (dried at 100°): granular pp.— $\text{Pb}_2\text{A}^{\text{vi}}$ (dried at 180°): bulky white pp.— $\text{Pb}_2\text{A}^{\text{vi}}(\text{NH}_3)_{12}$ 6aq: colourless trimetric crystals Karmrod, *A.* 81, 134).— $\text{Ag}_2\text{A}^{\text{vi}}$: white crystalline powder (Wöhler, *A.* 80, 1).

Methyl ether $\text{Me}_2\text{A}^{\text{vi}}$. [187°]. From silver mellitate and MeI (Kraut, *J.* 1862, 281; *A.* 177, 73). Plates. H.C. 1,825,600. H.F. 487,400 Stohmann, *J. pr.* [2] 40, 353).

Ethyl ether $\text{Et}_2\text{A}^{\text{vi}}$. [73°].

Isoamyl ether $(\text{C}_4\text{H}_{11})_2\text{A}^{\text{vi}}$. Oil.

Chloride $\text{C}_6(\text{COCl})_2$. [190°] (Claus, *B.* 10, 61). Formed, together with an oxychloride $\text{C}_6\text{O}_2\text{Cl}_2$, from PCl_5 and mellitic acid. Hard vitreous prisms (from ether). Sublimes in laminae at 240° . Slowly decomposed by water into HCl and mellitic acid.

Tri-imide $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ i.e. •

$\text{C}_6\left\{\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\right\}\text{NH}$ }. *Paramide*. Formed, together with euchroic acid, by heating ammonium mellitate at 160° as long as NH_3 escapes. Water extracts ammonium euchroate from the residue leaving paramide undissolved (Wöhler, *A.* 37, 268; Schwarz, *A.* 66, 52). White amorphous powder, insol. water and alcohol. Sol. H_2SO_4 but reppd. by water. Boiling with water slowly converts it into $(\text{NH}_4)_2\text{H}_2\text{C}_6\text{O}_{12}$. Alkalis convert it first into euchroic and then into mellitic acid. AgNO_3 forms in its ammoniacal solution a gelatinous pp. which gives off NH_3 when heated, leaving $\text{Ag}_2\text{N}_2\text{C}_6\text{O}_{12}$. An ammoniacal solution of paramide dropped into HClAq gives a white crystalline pp. called 'paramic acid' $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ (?) or CO_2H
 $\text{CO}(\text{NH}_2)_2\text{C}_6\left\{\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\right\}\text{NH}$ }.

Tri-phenyl-tri-imide

$\text{C}_6\left\{\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\right\}\text{NPh}$ }. Formed by heating mellitic acid or ammonium mellitate (1 mol.) with aniline (6 mols.) at 160° for 7 hours (Hötte, *J. pr.* [2] 32, 238). White amorphous mass.

Di-imide $\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$ i.e.

$(\text{CO}_2\text{H})_2\text{C}_6\left\{\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\right\}\text{NH}$ }. *Euchroic acid*.

Prepared by heating ammonium mellitate at 160° for several hours, dissolving in water, and adding HCl to the hot solution. The crystals which separate on cooling are recrystallised from water (Wöhler, *P.* 52, 610; Schwarz, *A.* 66, 49). Small prisms (containing 2aq); sl. sol. cold water. Strongly acid. Melts about 289° . Euchroic acid is not decomposed by boiling water or HClAq . When a solution of euchroic acid is treated with zinc the metal becomes covered with a dark-blue deposit of 'euchrone.' This deposit detaches itself when the zinc is immersed in dilute HClAq . After drying, euchrone is a black mass which becomes colourless when heated in air, being re-oxidised to euchroic acid. Euchrone forms a deep-purple solution in NH_4Aq or KOHAc , but the solution is quickly decolourised by the air. When a solution of euchroic acid is electrolysed, the negative platinum becomes coated with the blue deposit.

Salts.— $(\text{NH}_4)_2\text{C}_{12}\text{H}_2\text{N}_2\text{O}_8$: white crusts. An acid ammonium salt separates from hot solutions in yellowish crystals.— $\text{Ba}_2\text{A}^{\text{vi}}$ aq: pale-yellow powder.— PbA^{vi} aq.— PbA^{vi} 4aq.— $\text{Ag}_2\text{A}^{\text{vi}}$: sulphur-yellow powder.

Hexahydrate $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_6$. *Hydromellitic acid*. Formed by treating an ammoniacal solution of mellitic acid with sodium-amalgam; neutralising with acetic acid; ppg. by lead acetate; and decomposing the pp. with H_2S (Baeyer, *A. Suppl.* 7, 15). Formed also in the electrolysis of aqueous KOH with a positive electrode of carbon (Bartoli a. Papasogli, *C. C.* 1881, 827). Hygroscopic syrup; v. e. sol. water. By heating with H_2SO_4 (5 pts.) there is formed, together with CO_2 and SO_2 , trimelic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_3$, prehnitic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$, mellophanic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})$, and prehnomalic acid $\text{C}_{10}\text{H}_8\text{O}_8$.

Salts.—The alkaline salts are gummy, v. e. sol. water.—The calcium salt is more soluble in hot than in cold water.— $\text{Pb}_2\text{A}^{\text{vi}}$ (dried at 150°). Amorphous pp.— $\text{Ag}_2\text{A}^{\text{vi}}$: amorphous pp.

Isohexahydrate $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_6$. *Isohydromellitic acid*. Formed by heating the preceding hexahydrate with conc. HClAq for 3 hours at 180° (Baeyer). Prisms (from water). V. sol. water, but ppd. on addition of HCl. Not affected by heating with fuming HClAq at 300° . Decomposed in the same manner as its isomeride when heated with H_2SO_4 . Chromic acid mixture oxidises it to acetic acid and CO_2 .— $\text{Pb}_2\text{A}^{\text{vi}}$.

Methyl ether of the Isohexahydrate $\text{Me}_6\text{C}_{12}\text{H}_2\text{O}_{12}$. [125°]. Needles, v. e. sol. alcohol.

References. — **HEMI-MELLITIC ACID**; **PYROMELLITIC ACID**.

TRIMELLITIC ACID $\text{C}_6\text{H}_4\text{O}_8$ i.e.

$\text{C}_6\text{H}_4(\text{CO}_2\text{H})_3$ [1:2:4]. *Benzene tricarboxylic acid*. Mol. w. 210. [218°].

Formation.—1. Together with isophthalic acid and pyromellitic anhydride by heating the tetrahydride of pyromellitic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_4$ with 5 pts. of H_2SO_4 (Baeyer, *A. Suppl.* 7, 40).—2. By oxidising the acid $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$, prepared from ψ -cumene, by KMnO_4 (Krinov, *B.* 10, 1491).—3. By oxidising alizarin carboxylic acid with dilute HNO_3 (Hammerschlag, *B.* 11, 88).—4. By oxidising the acid $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$ with dilute nitric acid (S.G. 1:12) at 240° (Effront, *B.* 17, 2338).—5. By the action of cuprous cyanide upon the diazo-compound from amidoterephthalic acid, and saponification of the product with aqueous KOH (Ahrens, *B.* 19, 1634).—6. By heating mono-potassic (β)-sulphophthalate with sodium formate, isophthalic acid being also formed (Graebe a. Reé, *C. J.* 49, 532).

Preparation.—100 g. pulverised colophony and 2 litres of nitric acid (1 vol. commercial acid to 2 vols. water) are introduced into a retort with its beak directed upwards, and the liquid is heated to boiling, whereupon the colophony melts, and is quickly attacked, with copious evolution of red vapours, and converted into an orange-yellow viscid mass. After the boiling has been continued for 6 or 8 hours, fresh resin and strong nitric acid are added alternately, till about 1 kg. resin has been introduced, the contents of the retort being kept in constant ebullition; this process takes about a fortnight. The resulting wine-yellow liquid, which on addition of water should merely show turbidity, and not yield any lumpy precipitate, is then distilled off till the remaining liquid begins to froth; and

this liquid, while still hot, is poured into a ten-fold volume of cold water, decanted after twenty-four hours from the varnish-like resin which separates, and evaporated to a syrupy consistency. The whole then solidifies after a while to a thick crystalline pulp, which may be freed from the syrupy mother-liquor by means of an aspirator and porous earthenware plates, and afterwards boiled with water. The extract on cooling deposits isophthalic acid in slender needles, and on further concentration, first a little more of the same acid and then trimellitic acid, which may be purified by solution in alcohol and crystallisation from water. 30 g. of trimellitic acid may be thus obtained from 50 g. of resin (Schreder, A. 172, 93).

Properties.—Rosettes of small needles; m. sol. water and ether. When heated above its melting-point the anhydride distils over, condensing in concentrically arranged groups of needles. On fusion with NaOH it gives benzene and diphenyl (Barth a. Schreder, B. 12, 1257). It also yields benzene when distilled with lime.

Salts.—Ba.A''', 4aq (when air-dried). Gives off 8aq at 160°. Sl. sol. water.—Ba₃A''', 8aq (when dried over H₂SO₄).—Ag₃A''': white pp., not much affected by light: sl. sol. water.

Anhydride C₆H₂(CO₂H)₂ <CO>O. [158°]. Formed by heating the acid (Baeyer, A. 166, 340). Crystalline mass, sl. sol. cold, v. sol. hot, water.

Reference.—SULPHO-TRIMELLITIC ACID.

MELLITYL ALCOHOL v. PENTA-METHYL BENZYL ALCOHOL.

MELLOGEN C₁₁H₈O₄. On the electrolysis of water by a battery of 1,200 Daniell's cells, the anode being gas-carbon, the liquid becomes of an inky colour, and there is deposited in the voltmeter a black residue. This is washed with water until the filtrate is quite colourless; from the washings the mellogen is ppd. with a small quantity of dilute hydrochloric acid (Bartoli a. Papasogli, G. 11, 468; 12, 117; 13, 87; 15, 464; C. R. 94, 1339. A. Ch. [6] 7, 364). A black solid, of conchoidal fracture, sol. water and alkalis, insol. alcohols and hydrocarbon, and in most mineral acids and salts. It is not readily combustible, and is converted by oxidising agents, e.g. NaOCl, into mellitic and pyromellitic acid and their hydrides. At ordinary temperatures it has the composition 2C₁₁H₈O₄ + 3H₂O; at 100° it may be represented by 2C₁₁H₈O₄.H₂O. The aqueous solution of mellogen is dark-coloured, and is ppd. by acids and by many salts. With baryta mellogen gives an insoluble pp. Nitric acid (S.G. 1.36) oxidises mellogen forming an amorphous compound C₁₁H₈O₈, sol. water, alcohol, and ether: a soluble acid C₁₁H₈O₇, 2½aq, forming the salts Ba₂(C₁₁H₈O₇)₂ and Ag₂C₁₁H₈O₇; and a black compound resembling mellogen.

MELLONE v. CYANIC ACIDS.

MELLOPHANIC ACID C₁₀H₆O₆, i.e. C₆H₄(CO₂H)₂. [1:2:3:5]. *Benzene i-tetra-carboxylic acid*. [288°]. Obtained, together with prehnitic acid C₆H₄(CO₂H)₂, [1:2:3:4], by heating the hydride of pyromellitic acid C₆H₄(CO₂H)₂, [1:2:4:5] with H₂SO₄ (Baeyer, A. 166, 327). Formed also by the oxidation of iso-durene C₁₀H₈Me₂ (Jacobson, B. 17, 2516). Small four-sided prisms; v. sol. water, but ppd. by HCl from a conc. solu-

tion. Converted into an anhydride on fusion. Calcium acetate gives in hot solutions of the acid a pp. which re-dissolves on cooling. Baryta-water gives a pp. which becomes crystalline on heating. Lead acetate gives a flocculent pp., insol. acetic acid. Sodium-amalgam forms a hydride of mellophanic acid.

Anhydride [238°]. Formed by fusing the acid. Insol. ether.

MELOLONTHIN C₈H₁₂N₂SO₄. Found, together with leucine and hypoxanthine, in cockchafters (*Melolontha vulgaris*). The insects are extracted with water, the extract boiled, ppd. with lead subacetate, and the filtrate freed from lead by H₂S and evaporated. The crystals are freed from leucine by treatment with alcohol (Schreiner, B. 4, 763). 30lbs. of cockchafters yield 1.5 g. melolonthin. Silky needles (from water); sl. sol. cold, m. sol. hot, water; v. sl. sol. dilute alcohol and ether; v. sol. acids and alkalis. Does not act on light.

MELMESIDINE v. DIMESITYL-GUANIDINE.

MENAPHTHYLAMINE C₁₁H₉N i.e.

C₁₀H₇.CH₂NH₂. (292°). Formed by treating the amide of (a)-thionaphthoic acid C₁₀H₇.CS.NH₂ with zinc and HCl (Hofmann, B. 1, 100). Alkaline liquid, readily absorbing CO₂ from the air.—B'HCl: long, sparingly soluble crystals.—B'H₂PtCl₄: yellow crystalline pp.

MENISPERMINE C₁₁H₁₁N₃O₂ (?). [120°]. Occurs in the seeds of *Menispermum cocculus* (Pelletier a. Caventou, A. Ch. [2] 54, 178). To extract the menispermine, the alcoholic extract of the seeds is first treated with cold water, then exhausted with hot acidulated water; the brown solution is ppd. by an alkali; and the pp. is exhausted with very weak acetic acid, which leaves a brown-black mass undissolved. Or the seeds may be made up into a heap, and exhausted with alcohol of specific gravity 0.833; the alcohol distilled off; the residue boiled with water; and the liquid filtered at the boiling heat; it then, on cooling, deposits crystals of picrotoxine, especially if a small quantity of acid has been added. The part insol. boiling water is then treated with acidulated water, and ppd. by an alkali; a granular pp. is thereby formed, from which alcohol extracts a peculiar yellow substance; and the residue is finally dissolved in ether, which deposits menispermine in the crystalline form. The ether leaves undissolved a viscous substance, which may be dissolved in absolute alcohol: and the solution, evaporated at 45°, ultimately yields crystals of paramenispermine.

Properties.—Prisms; insol. water, sol. alcohol and ether. Is not poisonous. Its sulphate forms prismatic needles, sol. water.

Paramenispermine [250°]. Isomeric with menispermine. Insol. water, sl. sol. ether, v. sol. boiling alcohol. Dissolves in dilute acids.

MENTHENE C₁₀H₁₆. Mol. w. 138. (167.4° cor.) (Atkinson a. Yoshida, C. J. 41, 53); (163°) (Oppenheim, C. J. 15, 29). V.D. 4.94 (calc. 4.78). S.G. 1.814; d. 8226; η . 8073 (A. a. Y.). C.E. (0°-10°) .000994; (0°-60°) .00400. $[\alpha]_D$ +13.25 (A. a. Y.). n_D 74.0. *Specific refractive energy*, .548. *Specific dispersive energy*, .0313 (Gladstone, C. J. 49, 622). Obtained by distilling manthol (1 pt.) with ZnCl₂ (2 pts.), or with P₂O₅ (Walter, A. 32, 288). Formed also by the action

of conc. H_2SO_4 on menthol (Beckmann, *A.* 250, 359).

Properties.—Colourless oil, smelling like *cymene*; m. sol. ether and alcohol, v. sol. benzene, turpentine, and petroleum. Dextrorotatory.

Reactions.—1. Combines with fuming HCl , forming a yellow oil $\text{C}_{10}\text{H}_{19}\text{Cl}$. Combines also with HI , forming $\text{C}_{10}\text{H}_{19}\text{I}$, identical with the product obtained by heating terpinene dihydro-diiodide $\text{C}_{10}\text{H}_{16}\text{I}_2$ with HI (Bouchardat & Lafont, *C. R.* 107, 916).—2. Combines with bromine, forming $\text{C}_{10}\text{H}_{18}\text{Br}_2$, which is split up by heat into HBr and *cymene* (Beckett & Wright, *C. J.* 29, 1). 3. Fuming nitric acid oxidises it to glutaric acid.

MENTHOL $\text{C}_{10}\text{H}_{18}\text{O}$ i.e.

propyl-phenol herahydrate. Mol. w. 156. $[\alpha]_D^{25}$ (212°) = -59.3 (Moriya); $[\alpha]_D^{25}$ = -59.6 (Oppenheim); = -49.4 in a 5 p.c. alcoholic solution at 22° (Arth, *A. Ch.* [6] 7, 438). $R_D = 77.4$ in a 21 p.c. benzene solution (Kanonnikoff, *J. pr.* [2] 31, 348). H.C. 1,509,100 (Lougouine, *A. Ch.* [5] 23, 387). Deposited in crystals when the essential oil of peppermint is kept for a long time or cooled to a low temperature (Dumas, *A.* 6, 252; Blanchet & Sell, *A.* 6, 293; Walter, *A.* 32, 288; Kane, *P. M.* 16, 418; Laurent, *Rev. Scient.* 14, 341; Oppenheim, *C. J.* 15, 24). Menthol is imported from Japan in the solid state as 'peppermint camphor' (Moriya, *C. J.* 39, 77). White crystals, smelling of peppermint; sl. sol. water, v. e. sol. alcohol, ether, CS_2 , HOAc , and fixed and volatile oils. Insol. aqueous alkalis. From alcoholic NaOH it crystallises in long needles. Sodium dissolves in it with evolution of hydrogen. Conc. acids dissolve menthol, but it is reprecipitated on dilution with water. Menthol has the refractive and dispersive energy of a saturated compound (Gladstone, *C. J.* 49, 621). The rate of etherification of menthol by acetic acid is that of a secondary alcohol (Menschutkin, *J. R.* 13, 569).

Reactions.—1. With $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 in sealed tubes at 120° gives an inactive oil 'menthone' (205°), $\text{C}_{10}\text{H}_{18}\text{O}$, S.G. $\frac{15}{16}$.9032, sol. alcohol, ether, and chloroform.—2. Fuming HNO_3 forms an explosive oil, S.G. $\frac{15}{16}$ 1.061, which may be reduced to a yellow oil $\text{C}_{10}\text{H}_{16}\text{NH}_2$ (185°–190°). 3. Excess of fuming HNO_3 forms an acid, probably glutaric (*q.v.*).—4. Bromine in acetic acid forms $\text{C}_{10}\text{H}_{16}\text{Br}_2$. Unstable oil.—5. Conc. HCl at 100° slowly forms menthyl chloride. PCl_5 forms the same body.—6. ZnCl_2 or P_2O_5 dehydrate menthol, producing menthene.—7. KMnO_4 in acid solution forms (β)-pimelic acid $\text{C}_8\text{H}_{12}\text{O}_4$ [87°], of which the amide [191°] crystallises from water in prisms (Arth, *A. Ch.* [6] 7, 440; *C. R.* 107, 107). Formic, propionic, butyric, and oxymenthilic acids are formed at the same time. The oxymenthilic acid $\text{C}_{10}\text{H}_{18}\text{O}_4$ boils at 174° under 15 mm. pressure.—8. Boiled with HI (S.G. 1.7) for 3 days it forms a mixture of hydrocarbons chiefly consisting of $\text{C}_{10}\text{H}_{16}$ (168–6°) V.D. 67.25, $[\alpha]_D^{25}$ = +5.2. S.G. $\frac{15}{16}$.8254; $\frac{15}{16}$.8111; C.E. (0°–10°) .000929; (0°–60°) .000694. R_D 73.28. Colourless oil; v. sol. petroleum or

benzene, less so in alcohol or ether. Odour resembles *cymene* (Atkinson & Yoshida, *C. J.* 41, 54).—9. Menthol does not react with hydroxylamine (Nägeli, *B.* 16, 499).—10. On heating with sodium and ether on the water-bath, and, after cooling, adding CS_2 , there is formed menthyl-xanthogenic acid $\text{C}_{10}\text{H}_{17}\text{O.CS.SH}$, a liquid which undergoes spontaneous decomposition, but forms a yellow crystalline copper salt CuA'_2 (Bamberger & Lödter, *B.* 23, 213).

Acetyl derivative $\text{C}_{10}\text{H}_{17}\text{OAc}$. *Menthyl acetate*. (223°). $[\alpha]_D^{25}$ = -114°. From menthol and HOAc at 120° (Oppenheim, *C. J.* 15, 26). Liquid. Not decomposed by cold alkalis, but saponified by alcoholic NaOH at 120°.

Butyryl derivative $\text{C}_{10}\text{H}_{17}\text{O.CO.C}_2\text{H}_5$. *Menthyl butyrate*. Obtained by heating menthol with butyric acid at 200° for 30 hours (Oppenheim). (230°–240°). $[\alpha]_D^{25}$ = -89°.

Benzoyl derivative $\text{C}_{10}\text{H}_{17}\text{OObz}$. [54°]. (230°). $[\alpha]_D^{25}$ = -91°. In a one p.c. benzene solution, trimetric crystals partially decomposed on distillation into menthene and benzoic acid (Arth, *A. Ch.* [6] 7, 479).

Carbamyl derivative $\text{C}_{10}\text{H}_{17}\text{NO}_2$ i.e. $\text{C}_{10}\text{H}_{17}\text{O.CO.NH}_2$. *Menthyl carbamate*. [165°]. $[\alpha]_D^{25}$ = -85° in a .58 p.c. chloroform solution at 21°. Formed by passing dry cyanogen into a solution of sodium-menthol in dry toluene. The product is washed with water and the toluene distilled off. The crystalline mass is then recrystallised from alcohol, from which the carbamyl derivative separates in slender prismatic needles (Arth, *C. R.* 94, 872; 98, 521; *A. Ch.* [6] 7, 433). Needles; m. sol. alcohol and benzene. Sublimes at 100°. Decomposes at about 200°, yielding cyanuric acid. Alcoholic KOH forms menthol and potassium cyanate. Ac_2O at 130° forms $\text{C}_{10}\text{H}_{17}\text{OAc}$. Benzoic aldehyde and HCl form $(\text{C}_{10}\text{H}_{17}\text{O.CO.NH})\text{CHPh}$ [143°].

Carbonyl derivative $(\text{C}_{10}\text{H}_{17}\text{O})_2\text{CO}$. *Menthyl carbonate*. [105°]. Obtained in the preparation of the carbamyl derivative by evaporating the alcoholic mother-liquor and boiling the residue with water as long as menthol and ammonia come off. On cooling, the carbonyl derivative is deposited as a crystalline mass, sol. boiling alcohol (Arth). Plates (from alcohol) or prisms (from toluene); v. sl. sol. alcohol, v. sol. ether and benzene. Alcoholic KOH at 100° saponifies it.

Phenyl-carbamyl derivative $\text{C}_{10}\text{H}_{17}\text{O.CO.NHPh}$. *Menthyl phenyl-urethane*. *Menthyl phenyl-carbamate*. [111°]. From menthol and phenyl cyanate (Leuckart, *B.* 20, 115). Silky needles (from hot alcohol).

Succinoxyl derivative $\text{C}_{10}\text{H}_{17}\text{O.CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$. [62°]. $[\alpha]_D^{25}$ = -59.6° in a 1.4 p.c. benzene solution. Formed by heating menthene (1 mol.) with succinic anhydride (1 mol.) at 110° (Arth). Acicular crystals; v. e. sol. alcohol, v. sl. sol. hot water. Its Na and K salts are very deliquescent; the Ca and Ba salts are white pps.— $\text{AgC}_{10}\text{H}_{17}\text{O}_2$; small needles (from hot water).

Succinyl derivative $(\text{C}_{10}\text{H}_{17})_2\text{C}_2\text{H}_2\text{O}_4$. [62°]. (220°). $[\alpha]_D^{25}$ = -81.5° in a 1.9 p.c. benzene solution. From menthol (1 mol.) and succinic acid (2 mols.) at 150°. Trimetric crystals (from alcohol). Decomposes on distillation into succinic acid and menthene.

Phthaloyl derivative $C_{18}H_{16}O_4$ *i.e.* $C_{10}H_{10}O_4 \cdot CO_2C_6H_4CO_2H$ [110°]. $[\alpha]_D = -105.6^\circ$ in a 1.6 p.c. benzene solution. Formed by heating menthol (1 mol.) with phthalic anhydride (1 mol.) at 110° (Arth.). Minute needles; insol. cold water, v. sol. alcohol and ether. Gives white pps. with Ba and Ca salts. — $Mg(C_{10}H_{10}O_4)$: laminæ; almost insol. cold water.

Phthalyl derivative $C_{20}H_{18}O_4$ *i.e.* $(C_{10}H_{10})_2C_6H_4O_2$ [133°]. $[\alpha]_D = -94.7^\circ$ in a 2 p.c. benzene solution at 20°. From phthalic anhydride (1 mol.) and menthene (2 mols.) at 140°. Trimetric crystals (from ether); sl. sol. boiling alcohol.

Menthyl chloride $C_{10}H_{19}Cl$ (c. 204°). Obtained by treating menthol with PCl_5 (Walter, A. 82, 292) or with conc. $HClAq$ for a week at 100° (Oppenheim). The same body appears to be formed by heating menthene with fuming $HClAq$ at 120° (Arth., C. R. 97, 323). Light oil; sl. sol. water, m. sol. alcohol. Not attacked by alcoholic KOH . With sodium menthol it gives menthene and menthol.

Menthyl bromide $C_{10}H_{19}Br$. From menthol and bromide of phosphorus. Non-volatile liquid. Gives with bromine $C_{10}H_{17}Br_2$.

Menthyl iodide $C_{10}H_{19}I$. From menthol and conc. $HIAq$. Liquid; decomposed by alcoholic K_2S into menthene and HI .

Tetra-menthyl-silicate $Si(O_2C_{10}H_{19})_4$ [82°]. (350°) at 155 mm. Formed by the action of $SiCl_4$ upon menthol; the yield is 75 p.c. of the theoretical (Hertkorn, B. 18, 1695). Colourless prisms; v. sol. ether, benzene, ligroin, chloroform, CS_2 , and warm alcohol; sl. sol. cold alcohol.

Oxymenthyl acid $C_{10}H_{18}O_4$ (175°) at 15 mm. (280°). A product of the oxidation of menthol by $KMnO_4$ (Arth., A. Ch. [6] 7, 448). Colourless liquid, partially decomposed on boiling at 280°; v. sl. sol. water, v. sol. alcohol and ether. The salts of alkalis and alkaline earths are very soluble. A solution of the sodium salt is ppd. by salts of Pb , Fe''' , Cu , and Pt . It forms no acetyl derivative. — AgA' . — NaA' : white deliquescent crystals.

Methyl ether MeA' . (137°) at 17 mm. Liquid.

Ethyl ether EtA' . (145°) at 18 mm. Thick liquid.

MENTHONE $C_{10}H_{18}O$ (206.3° cor.). $[\alpha]_D = +21^\circ$. S.G. 2-9126; d_4^{20} 0.8972. C.E. (0°-10°) -000862; (0°-100°) -000923. R_D 75.3. From menthol (80 g.), $K_2Cr_2O_7$ (10 g.), and H_2SO_4 (10 g.) at 135°. The light oil is subjected several times to the action of the same oxidising mixture (Atkinson & Yoshida, C. J. 41, 49). Colourless oil, miscible with alcohol, chloroform, benzene, and OS_2 . Smells like diluted peppermint. Does not combine with $NaHSO_4$. If a solution in petroleum is treated with Na and CO_2 successively and then shaken with water crystals of menthol are got (42°); but having $[\alpha]_D = -89^\circ$ not -59°.

Lævo-menthone $C_{10}H_{18}O$ *i.e.*

$CHPr \cdot \begin{array}{c} CH_2 \cdot CH \\ | \quad | \\ CH_2 \cdot CO \end{array} \cdot CHMe(?)$ (207°). S.G. 2-8960.

$[\alpha]_D = -28.2^\circ$. Menthone is a mixture of two isomerides—one dextro-, the other lævo-rotatory. By using very little acid the lævo-menthone may be obtained free from dextro-menthone and menthol. The best proportions are 60 g. $K_2Cr_2O_7$, 50 g. H_2SO_4 , 800 g. water, and

45 g. menthol, the mixture being kept at 80° to 55° (Beckmann, A. 250, 325). The menthone is extracted with ether, washed with dilute alkali, and distilled with steam.

Properties.—Mobile liquid, smelling faintly of peppermint; sl. sol. water, miscible with alcohol, ether, and petroleum-ether. The molecular weight determined by Raoult's method agrees with the formula. The molecular refraction $\left(\frac{n^2-1}{n^2+2}\right) \frac{P}{d}$ is 40.3. Lævo-menthone is

converted into a mixture of dextro- and lævo-menthone by acids, bases, water, heat, or even on keeping.

Oxim $C_{10}H_{17}NOH$. Mol. w. 169. [58°]. $[\alpha]_D = -42.5^\circ$. Crystalline; sl. dilute alcohol, ether, and petroleum-ether. Raoult's method gives, when acetic acid is used, the mol. w. 169, but when benzene is used it gives 251. With HCl the oxim forms a compound $(C_{10}H_{17}NOH)HCl$ [119°], a white crystalline powder. — $\rightarrow C_{10}H_{17}NONa$.

Dextro-menthone $C_{10}H_{18}O$. Mol. w. 154. (208°). S.G. 2-900. $[\alpha]_D = +28.14^\circ$. Obtained by freezing a mixture of H_2SO_4 (10 pts.) and water (1 pt.), adding menthene (2 pts.), and shaking. The temperature is slowly raised to 30°, the product poured into ice, and the menthone extracted by ether (Beckmann, A. 250, 334). Colourless mobile oil; sl. sol. water, miscible with alcohol, ether, and petroleum-ether. The mol. w. determined by Raoult's method is 150. The action of acids, bases, water, heat, and time convert dextro-menthone into a mixture of dextro- and lævo-menthone.

Oxim $C_{10}H_{17}NOH$. Thick oil, slightly lævo-rotatory. The mol. w. determined by Raoult's method is 165 when acetic acid is used, and 228 when benzene is employed as solvent. — $(C_{10}H_{17}NOH)HCl$ [c. 97°]. Deliquescent. — $\rightarrow C_{10}H_{17}NONa$.

MENYANTHIN $C_{10}H_{16}O_{11}$ [60°-115°]. A bitter glucoside found in buckbean (*menyanthes trifoliata*) (Brandes; Kromayer, Ar. Ph. [2] 108, 257; 124, 37; Fr. 1, 15). Prepared by treating the aqueous extract with animal charcoal at 65° and subsequently extracting the charcoal with alcohol. Amorphous yellowish mass; sl. sol. cold water, v. sol. hot water and alcohol, insol. ether. Dissolves in aqueous alkalis. Its solutions are not ppd. by metallic salts. It is ppd. by tannin. When distilled with dilute H_2SO_4 it gives off volatile menyanthol, while glucose $C_6H_{12}O_6$ remains behind.

Menyanthol $C_{10}H_{16}O$ is an oil smelling like benzoic aldehyde. It reduces ammoniacal $AgNO_3$. By exposure to the air, or by potash-fusion, it is converted into a crystalline sublimable acid.

Menyanthin. This name has also been applied to inulin when prepared from buckbean.

MERCAPTALS. Compounds of the form $ROH(SR')$. They may be viewed as thio-acetals or as the sulphur-compounds corresponding to the alkyl derivatives of ortho-aldehydes. **V. THIO-ALDEHYDES.**

MERCAPTAN C_2H_5S *i.e.* C_2H_5SH . *Ethyl mercaptan*. Thio-alcohol. Mol. w. 62. (36.5°). S.G. 2-8391. V.D. 2.11 (calc. 2.15). S.V. 76 (Lousen, A. 354, 71). H.F.p. 14,430. H.F.v.

18,271 (Thömsen). B_{∞} 18°62 (Nasini, G. 18, 801).

Formation.—1. By distilling calcium ethyl sulphate $CaEt_2(SO_4)$ with a solution of barium sulphhydrate (Zeise, P. 31, 869).—2. A mixture of alcohol and H_2SO_4 is neutralised with KOH, decanted from $ppd. K_2SO_4$, mixed with excess of KOH, saturated with H_2S , and distilled (Wöhler).—3. A solution of KOH (S.G. 1.3) is saturated with H_2S , mixed with an equal volume of a conc. solution of K_2SO_4 , and distilled from a water-bath (Liebig, A. 11, 14; 23, 34). The product is freed from Et_2S by fractional distillation (Claesson, J. pr. [2] 15, 193).—4. From KSH and $EtCl$ (Regnault, A. Ch. [2] 71, 890).—5. From KSH and EtI (Baudrimont, C. R. 54, 616).—6. By reducing with HI at 160° the solid thio-aldehyde obtained by passing H_2S into a mixture of aldehyde solution and iodine (Böttlinger, B. 11, 2203).—7. Together with $HEtSO$, and ether, by heating alcohol saturated with SO_2 in sealed tubes (Endemann, A. 140, 336; Pagliani, B. 11, 155).

Preparation.—A cold mixture of alcohol (1 litre) and H_2SO_4 (500 c.c.) is diluted with ice and then added to a solution of crystallised sodium carbonate (4 kilos). The product is concentrated until Na_2SO_4 separates. The mother-liquor is further concentrated, and mixed with KOH (800 g.) dissolved in water (1,500 c.c.) previously saturated with H_2S . The whole is heated on a water-bath, and the gases are passed first through a strong solution of caustic potash (50 g.) and then into a solution of KOH (350 g.) in water (700 g.). The small amount of H_2S contained in the latter solution is $ppd.$ by lead acetate, and the mercaptan liberated by HCl. It is dried with K_2CO_3 and distilled (Klason, B. 20, 847).

Properties.—Colourless, very mobile, liquid, having a peculiarly persistent alliaceous odour. V. sl. sol. water, miscible with alcohol and ether. • Very inflammable, and burns with a blue flame. A drop of it when briskly agitated on the end of a glass rod becomes solid, possibly through formation of a hydrate. Neutral to litmus. An alcoholic solution forms a yellow $pp.$ with lead salts, and white $pps.$ with cupric acetate, mercuric salts, and trichloride of gold. The alcoholic solution is turned blue by $FeCl_3$ (Rathke, A. 161, 148). Mercaptan is a reducing agent; thus it converts nitro-benzene into azo-benzene. Mercaptan decomposes salts of phenyl with formation of sodium phenylate and a thio-ether (L. Seiffert, J. pr. [2] 31, 462). But with phenyl salicylate it acts thus: $C_6H_5(OH)CO_2Ph + NaSEt = C_6H_5(ONa)CO_2Ph + HSEt$. A trace of isatin dissolved in sulphuric acid gives, with a trace of mercaptan, a fine green colouration (Berthelot, C. R. 108, 850).

Reactions.—1. Boiling nitric acid (S.G. 1.4) becomes red, deposits an oil, and ultimately forms ethane sulphonic acid. Weaker nitric acid (S.G. 1.28) forms $EtSO_3SEt$.—2. Potassium forms hydrogen and $KSEt$.—3. P_2S_5 forms Et_2PS_3 and Et_2HPS_3 (Carius, A. 112, 190).—4. Bromine forms $EtBr$ and S_2Br_2 (Friedel & Ladenburg, A. 145, 189).—5. Heated in sealed tubes with diazo-compounds (diazo-salicylic acid, diazo-phenol chloride) it forms di-ethyl disulphide, the diazo-compound being reduced exactly as when

boiled with alcohol (B. Schmitt & O. Mittenzwey, J. pr. 126, 192): $C_6H_5(OH).N:NCl + 2EtSH = Et_2S_2 + N_2 + C_6H_5.OH + HCl$.—6. PCl_5 at 100° forms thiophosphorous ether $P(SEt)_3$, a feebly oil, resolved by distillation into phosphorus and Et_2S_2 .—7. CCl_4 , acting on $NaSEt$, forms $C(SEt)_4$, a light oil, S.G. 1.01, decomposed on distillation. C_2Cl_6 with $NaSEt$ gives $C_2(SEt)_6$, a heavy feebly oil, solidifying at very low temperatures. C_2Cl_6 heated with $NaSEt$ at 100° gives $C_2(SEt)_6$, crystallising in rhombohedra [54°].—8. S_2Cl_2 forms HCl and Et_2S_2 , which is resolved by distillation into Et_2S_2 and S_2 .—9. $TiCl_4$ gives $EtSHTiCl_3$ and $(EtSH)_2TiCl_2$ (Demarçay, Bl. [2] 20, 132).—10. Reacts with ketones forming 'mercaptols' or thioketates. Thus HCl passed into a mixture of acetone and mercaptan forms $(CH_3)_2C(SEt)_2$ (Baumann, B. 18, 887).—11. Mercaptan suspended in ice-water and mixed with diazobenzene sulphonic acid and soda gives explosive yellow needles of $SO_2Na.C_6H_5.N_2SEt$. When the alcoholic solution of this salt is boiled $SO_2Na.C_6H_5.N_2SEt$ and nitrogen are formed (Stadler, B. 17, 2075).

Salts.—All metallic mercaptides are decomposed by HCl .— $KSEt$. From mercaptan and K. Dull white granular mass, v. sol. water, sl. sol. alcohol. Its aqueous solution gives a yellow $pp.$ with lead salts.— $NaSEt$. From mercaptan and Na or $NaOEt$. Crystalline mass, v. sol. water and alcohol. Its aqueous solution is alkaline in reaction, and gives off all its mercaptan on boiling. In dry air it oxidises to $C_6H_5SO_3Na$. When oxygen is passed through its alcoholic solution Et_2S is formed.— $Zn(SEt)_2$: white, indistinctly crystalline $pp.$ obtained by adding mercaptan to aqueous zinc acetate. Sol. NH_4Aq and reprecip. on neutralisation.— $Cd(SEt)_2$.— $Co(SEt)_2$: gummy $pp.$ Unlike the other mercaptides it is not attacked by fuming HNO_3 .— $Ni(SEt)_2$: chocolate brown powder, not decomposed by water.— $Fe(SEt)_2$: from $FeCl_3$, mercaptan, and ammonia. Black slimy mass, resolved by heating into mercaptan and ferrous hydrate.— $EtSFe(NO)_2$ [78°]. From $KSFe(NO)_2$ and EtI (Pavel, B. 15, 2607).— $TSEt$: yellow curdy $pp.$, sl. sol. water.— $Cu(SEt)_2$. Obtained by adding mercaptan to a solution of $CuSO_4$, mixed with $NaOAc$. Pale-yellow amorphous powder (Klason, B. 20, 3407).— $Hg(SEt)_2$ [77°]. S. 7 in 85 p.c. alcohol. Formed on shaking HgO with mercaptan or with an alcoholic solution of mercaptan, the action being attended with great evolution of heat. It is from this body that mercaptan derives its name (*corpus mercurio aptum*). White unctuous scales. When its alcoholic solution is heated to 190° it is decomposed into mercury and Et_2S_2 (Otto, B. 13, 1289; 15, 125). The same decomposition appears to occur when it is heated in the dry state. It is not decomposed by aqueous KOH, but aqueous K_2S forms some HgS and $KSEt$. H_2S forms HgS and mercaptan. Nitric acid oxidises it to $(C_6H_5SO_3)_2HgHgO$. When melted with lead the products are mercury, PBS , and Et_2S . Mercury mercaptide forms with iodoform needles of $(EtS)_2Hg.CHI_3$ (85-87°) (Jackson & Oppenheim, B. 8, 1038).— $EtSHgCl$. White bulky $pp.$ obtained on mixing an alcoholic solution of mercaptan with $HgCl_2$. Changes after some time to crystalline laminae. Sl. sol. water and ether,

m. sol. boiling alcohol (Debus, *A.* 72, 18).—**Pb(SET)**. Yellow pp., got by mixing alcoholic solutions of lead acetate and mercaptan. Decomposed by heating with alcohol at 190° into PbS and Et₂S.—**Bi(SET)**. [79°]. Obtained by mixing a solution of a salt of bismuth with mercaptan. Long flexible yellow needles, m. sol. alcohol and ether. Oxidises in the air. Resolved by heat into BiS and Et₂S.—**Sn(SET)**. Formed by mixing solutions of mercaptan and SnCl₂ in CS₂, and evaporating the solvent. Also from mercaptan and a conc. aqueous solution of SnCl₂. Oil, remaining liquid at -40°. May be distilled *in vacuo*, but when heated under atmospheric pressure it decomposes yielding Et₂S, and metallic tin.—**Sn(SET)₂**: yellow pp., which quickly oxidises in air.—**EtSSbCl**. Oil, formed by evaporating a mixture of mercaptan and SbCl₃. Decomposed by water with liberation of mercaptan.—**As(SET)**. Obtained by adding NaSEt to an ethereal solution of AsCl₃. Oil, with unpleasant odour. Decomposed on distillation into arsenic and Et₂S.—**ClAs(SET)**. From AsCl₃ and mercaptan in the cold.—**EtSAu**. White gelatinous pp. obtained on mixing dilute alcoholic solutions of auric chloride and mercaptan.—**Pt(SET)₂**: light yellow pp.—**Rh₂(SET)₄**: yellow pp.

Hydrate EtSH 18H₂O. Solidifies as a crystalline mass when moist vapour of mercaptan is passed through a condenser cooled below 8° (H. Müller, *Ar. Ph.* [2] 150, 147). Mass of small needles, insol. water and mercaptan. A compound containing 1.6 p.c. carbon, crystallising in prisms, is obtained by pouring mercaptan into a solution of H₂S at 0°. It perhaps contains H₂S as well as water. It melts and decomposes above 8° (Blaikie, *Pr. E.* 10, 87).

MERCAPTANS. (Sulphydrates.) Compounds of the formula RSH where R is a hydrocarbon radicle. They may be viewed as acid ethers of sulphydric acid or as alcohols in which O has been displaced by S. Just as H₂S is more acid than H₂O, the mercaptans are more acid than the alcohols. Thus they readily form salts by reacting with metallic oxides, and they derive their name from the ease with which they form mercuric salts. The salts of mercaptans may be called mercaptides. The mercaptans boil at a lower temperature than the corresponding alcohols, just as H₂S has a lower boiling-point than H₂O. The mercaptans have an unpleasant odour. They are very readily oxidised, forming disulphides R₂S₂, and finally sulphonic acids RSO₃H. The oxidation to sulphonic acids is best effected by nitric acid, and the chlorides of the sulphonic acids RSO₂Cl when reduced by tin and HCl yield the mercaptans again (Vögt, *A.* 119, 152). By heating mercaptans with H₂SO₄ disulphides R₂S₂ are formed (Erlenmeyer a. Lisenko, *J.* 1861, 590).

Preparation.—1. Fatty, but not aromatic, mercaptans are formed by heating a solution of KSH with alkyl chlorides or iodides or with potassium alkyl sulphates.—2. By heating alcohols or phenols with P₂S₅ (Kekulé, *A.* 90, 811; *Z.* 1867, 193). The yield is small.—3. By reducing chlorides of sulphonic acids with zinc or tin and dilute H₂SO₄ or HCl. This process is very convenient for the preparation of aromatic mercaptans. The product is distilled with steam.

4. Aromatic mercaptans may be prepared by treating diazo-compounds with K₂S (Klason, *B.* 20, 850).—5. Aromatic mercaptans may be obtained by reducing the corresponding disulphides with zinc and H₂SO₄.—6. Aromatic mercaptans can be formed, together with the corresponding sulphides, by the action of aluminium chloride on a mixture of hydrocarbon and sulphur at 80° (Friedel a. Crafts, *Bl.* [2] 31, 464).—7. When three atoms of hydrogen in the benzene nucleus have been displaced by chlorous radicles, and two of these are NO₂ and a halogen in ortho-position to each other, alcoholic KSH displaces the halogen by SH (Beilstein a. Kurbatoff, *A.* 197, 75).—8. By treating aromatic diazo-compounds with sodium thiosulphate and reducing the resulting aromatic thiosulphates with zinc and H₂SO₄ (Lœwckart, *G. P.* 1887, 45, 120).

Properties.—Oils or crystalline solids with unpleasant odour. Insol. water. The salts of the heavy metals are sparingly soluble in water. The mercuric salts can usually be recrystallised from alcohol. When a small quantity of a 1 p.c. solution of isatin in H₂SO₄ is mixed with a few c.c. of the strong acid and a small quantity of a fatty mercaptan, a green colouration is produced. Aldehydes and the higher alcohols interfere with the isatin reactions, and in this case the liquid may be shaken with a solution of KOH and then mixed with a little sodium nitroprusside, when a reddish-violet colouration is produced (Denigès, *C. R.* 108, 350). The alkyl sulphides do not give this reaction. When sulphides are present they should first be ppd. by an alkaline solution of PbO.

Reactions.—1. The ammoniacal solutions of aromatic mercaptans oxidise in the air with formation of disulphides.—2. When HCl is passed into a mixture of a ketone and a mercaptan condensation takes place and a thioester or 'mercaptole' is formed, e.g.:

These anhydro-compounds may even be formed by boiling the alkoyl derivatives of aromatic amines with sulphur. They are also formed by the oxidation (by K₂FeCy₆) of the thio-alkoyl derivatives of aromatic amines. They are volatile liquids which exhibit feeble basic characters, and regenerate the amido-mercaptans when fused with potash (Hoffmann, *B.* 18, 8, 1223; Jacobsen, *B.* 19, 1069). When o-amido-mercaptans are diazotised they produce characteristic stable compounds of the form C₆H₄ $\begin{array}{c} \text{N} \\ \text{S} \end{array}$ N.

MERCAPTURIC ACIDS. Acids obtained by placing chloro- or bromo-benzene in food eaten by dogs. **V. BROM-PHENYL- and CHLORO-PHENYL-MERCAPTURIC ACIDS.**

MERCURAMMONIUM COMPOUNDS. (Ammonio-mercury compounds. Ammoniacal mercury bases. Mercuramines.) By the reactions of ammonia, or ammonium salts, on compounds of Hg, compounds are obtained, many of which may be represented by the empirical formulæ $xHgX_y.NH_3$ and $xHgX_y.NH_3$, where X = acid radicle; some of the compounds, however, con-

tain N and H in the ratio $N:H_2$; and some are composed of N, Hg, and acidic radicles only. The mercurammonium compounds, as a class, do not react as loose compounds of Hg salts with NH_3 , but rather as compounds of Hg, N, H, and acidic radicles.

The mercurammonium compounds were regarded by Kane as compounds of NH_2Hg . Thus, the compound $HgO.NH_2$ was formulated as $NH_2Hg.OH$, and the compound $HgSO_4.2NH_3$ as $NH_2Hg.O.SO_4ONH_2$, (*A. Ch.* [2] 72, 215). Hirzel (*A.* 84, 258) represented the mercurammonium compounds as compounds of mercuric nitride, N_2Hg_2 . Gerhardt suggested that these compounds are derived from NH_2 by replacing H by Hg; and after the ammonium hypothesis had been somewhat developed, Hofmann attempted to derive the compounds in question from different hypothetical mercurammoniums, i.e. compounds formed by replacing the H of NH_4 more or less completely by Hg (*v. Handwörterbuch der Chemie* [2nd ed.] 2, 751; cf. Schmieder, *J. pr.* 75, 147; Nessler, *J.* 1856, 409). On this view, the compounds $HgCl_2.2NH_3$ and $HgSO_4.2NH_3$

are represented as $Hg \begin{smallmatrix} NH_2Cl \\ NH_2Cl \end{smallmatrix}$ and

$Hg \begin{smallmatrix} NH_2 \\ NH_2 \end{smallmatrix} SO_4$, derived from NH_2Cl and

$NH_4 \begin{smallmatrix} \\ \\ \end{smallmatrix} SO_4$. The mercurammonium compounds

may be divided, on this view, into classes according to the hypothetical Hg derivative of ammonium from which they are supposed to be derived. Thus we have the following: N_2H_4Hg = mercurammonium, $N_2H_4Hg_2$ = mercurousammonium, $N_2H_4Hg_3$ = dimercurammonium, $N_2H_4Hg_4$ = trimercurammonium; the mercurammonium compounds are those containing divalent Hg, and the compounds of monovalent Hg are called mercurousammonium derivatives. The compound $2HgO.NH_3$, obtained by the reaction of HgO with NH_3 , is represented on the ammonium hypothesis as hydrated mercurammonium hydroxide, $NH_2Hg.OH.H_2O$.

A division is sometimes made between those mercurammonium compounds which contain N and H in the ratio $N:H_2$, and those which contain these elements in the ratio $N:H_4$; the latter are called mercuramide compounds.

Although some compounds readily give off NH_3 when heated, and others only when heated with alkali, yet it seems simpler to name all the compounds under consideration in accordance with the ammonium hypothesis. In this article the mercurammonium compounds are divided into two classes, mercurous and mercuric; the former being called mercurous- and the latter mercuric- compounds; the name given to each compound is intended to indicate the number of NH_2 groups from which the compound is derived, and the number of Hg atoms (mercurous or mercuric) in the formula. Several compounds are known whose reactions seem well expressed by supposing them to contain the group $HgO.Hg$; such compounds are called mercurous-ammonium derivatives in this article.

The following table presents the classification and nomenclature adopted in the present article:—

Class I. Mercurous compounds.

Series (i.) Mercurous-ammonium compounds; e.g. $(NH_2Hg)Cl$.

" (ii.) Dimercuro-ammonium compounds; e.g. $(NH_2Hg_2)Cl$.

Class II. Mercuric compounds.

Series (i.) Mercuric-ammonium compounds; e.g. $(NH_2Hg)Cl$.

" (ii.) Dimercuri-ammonium compounds; e.g. $(NH_2Hg_2)O$.

" (iii.) Mercuri-diammonium compounds; e.g. $(N_2H_4Hg)I$.

" (iv.) Dimercuri-diammonium compounds; e.g.

$(N_2H_4Hg_2)SO_4.H_2O$.

" (v.) Trimercuri-diammonium compounds; e.g.

$(N_2H_4Hg_3)SO_4.2H_2O$.

Class III. Mercurous-ammonium compounds; e.g. $(NH_2Hg_2O)OH$; $(NH_2Hg_2O)SO_4$.

Dimercuro-ammonium chloride $(NH_2Hg_2)Cl$ is sometimes called mercurio-chloramide or amido-mercurous chloride; to express this view of its constitution the formula is written $Hg_2(NH_2)Cl$. So also mercurous-ammonium chloride $(NH_2Hg)Cl$ is sometimes called ammonio-mercurous chloride, and the formula is written, empirically, $HgCl.NH_2$; the formula of this compound is frequently doubled, and the name mercurousammonium chloride— $(N_2H_4Hg_2)Cl_2$ —is given to it. The salts called in this article mercurous-ammonium compounds may be regarded as hydrated dimercuri-ammonium salts; thus, the chloride $(NH_2Hg_2O)Cl$ may be written $(NH_2Hg_2)Cl.H_2O$, and the carbonate $(NH_2Hg_2O)_2CO_3$ may be written $(NH_2Hg_2)_2CO_3.2H_2O$.

Class I. Mercurous compounds. $NH_2Hg.X$.

The experiments of Barfoed (*J. pr.* [2] 39, 201) make it probable that the so-called mercurous-ammonium compounds are really mixtures of mercuric compounds and Hg. B. asserts that exactly half the Hg in the black pps. formed by NH_3 in solutions of mercurous salts exists uncombined, that nearly the whole of this Hg disappears as vapour when the pps. are freely exposed to air, and that the light-coloured compounds remaining are the same as those produced by adding NH_3 to mercuric salts. To the pp. produced from $HgNO_3$, Barfoed gives the composition $3Hg + 2(HgNH_2.NO_3)HgO$; that produced from $HgSO_4$ is $4Hg + (NH_2Hg_2)SO_4.2HgO$; that from $HgCl$ is $Hg + NH_2HgCl$; and that from Hg_2O_2 is $4Hg + (NH_2Hg_2)C_2O_4.2HgO$.

Series (i.) Mercurous-ammonium compounds; NH_2HgX .

Mercurous-ammonium chloride, $(NH_2Hg)Cl$ (Ammonio-mercurous chloride $(HgCl.NH_2)$, Mercurous-ammonium chloride $(N_2H_4Hg_2)Cl_2$). A black powder, obtained by saturating HgCl, prepared by ppn., with NH_3 gas; on gently warming all NH_3 is given off (H. Rose, *P.* 20, 158). The dissociation of this compound has been studied by Isambert (*C. R.* 66, 1259; *v. Dissociation*, vol. ii. p. 397). According to Barfoed (*J. pr.* [2] 39, 201) the compound formulated as above is really a mixture of Hg, mercuri-ammonium chloride (NH_2HgCl) , and NH_4Cl .

Series (ii.) Dimercuro-ammonium compounds; NH_2Hg_2X .

MERCURAMMONIUM COMPOUNDS.

Mercurio-ammonium chloride, $(\text{NH}_4\text{Hg}_2)\text{Cl}$. (*Mercuriochloramide* or *amido-mercurous chloride* $(\text{Hg}_2\text{NH}_2\text{Cl})$. *Tetramercurio-diammonium chloride* $(\text{N}_2\text{H}_4\text{Hg}_4\text{Cl}_2)$.) A black solid, obtained by digesting HgCl with NH_4Aq ($2\text{HgCl} + 2\text{NH}_4\text{Aq} = \text{NH}_4\text{Hg}_2\text{Cl} + \text{NH}_4\text{ClAq}$). Becomes dark-grey when dried; heated, gives off NH_3 and N , and at a higher temperature yields a sublimate of HgCl and Hg ; treated with HCl gas, gives HgCl and NH_4Cl (Kane, *A. Ch.* [2] 72, 215; Ullgren, *P.* 42, 395). According to Barfoed (*J. pr.* [2] 89, 201) the black solid obtained as described is a mixture of Hg and NH_4HgCl .

Mercurio-ammonium nitrates. Various compounds of the form $x\text{Hg}_2\text{O}_3 \cdot y\text{N}_2\text{O}_5 \cdot z\text{NH}_3$ have been described by Kane (*l.c.*) and Mitscherlich (*P.* 9, 887; 16, 41); but Barfoed's experiments make it very probable that these bodies are mixtures of Hg and mercurio-ammonium salts (*v. supra*).

Class II. MERCURIC COMPOUNDS. $\text{N}_2\text{H}_4 \cdot y\text{Hg}_2\text{X}$.

Sériés (i.) Mercurio-ammonium compounds; NH_4HgX . Obtained by interaction of excess of NH_4Aq with mercuric salts in solution.

Mercurio-ammonium chloride, $(\text{NH}_4\text{Hg})\text{Cl}$. (*Mercurio-chloramide*, or *amido-mercuric chloride* $(\text{Hg}_2\text{NH}_2\text{Cl})$. *Dimercurio-diammonium chloride* $(\text{N}_2\text{H}_4\text{Hg}_2\text{Cl}_2)$. *Infusible white precipitate*.) According to Rammelsberg (*J. pr.* [2] 38, 558) this salt is a double compound of dimercurio-ammonium chloride— NH_4HgCl —and NH_4Cl ; R. assigns to it the formula $\text{NH}_4\text{HgCl.NH}_4\text{Cl}$ (*v. infra*).

When excess of NH_4Aq is added to HgCl_2Aq , or when HgCl_2Aq is dropped into NH_4Aq , a white pp. is obtained; this pp. was long considered identical with that obtained by adding $\text{Na}_2\text{CO}_3\text{Aq}$ to HgCl_2Aq mixed with NH_4ClAq , and known in pharmacy as *Mercurius precipitatus albus*. Wöhler (*P.* 26, 203) found that the pp. formed by NH_4Aq was volatilised without fusion when heated in a Pt dish, but that the pp. formed by $\text{Na}_2\text{CO}_3\text{Aq}$ melted before it volatilised. The pp. by NH_4Aq was then called *infusible white precipitate*, and to that produced by $\text{Na}_2\text{CO}_3\text{Aq}$ the name *fusible white precipitate* was given.

Preparation.— HgCl_2Aq is added to excess of cold NH_4Aq , the pp. is collected at once, rapidly washed with a little cold water, and dried at 110° (André, *C. R.* 108, 233, 290). André (*l.c.*) has examined the compounds obtained by the interaction of NH_4Aq with HgCl_2Aq , varying the relative masses of the reacting bodies and the time of contact. Using equal volumes of HgCl_2Aq , containing 33.875 g. HgCl_2 per litre, and NH_4Aq containing 4.25 g. NH_3 per litre, the pp. after drying at 110° was not quite pure NH_4HgCl , but contained a little mercurioxy-ammonium chloride $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$. The quantity of $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ increased by allowing the reacting bodies to remain in contact, and also by increasing the quantity of NH_4Aq ; when the NH_3 and HgCl_2 were present in the ratio $6\text{NH}_3:\text{HgCl}_2$, the pp. contained equal molecular proportions of NH_4HgCl and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$, and by further increasing the NH_3 , only $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ was obtained. André found that NH_4Cl tends to change $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ into NH_4HgCl ; by adding 1 vol. HgCl_2Aq to 5 vols. NH_4Aq (strength as given above), decanting after 24 hours, and agitating the pp. for 2 days with 2 vols. NH_4ClAq (containing 18.4 g.

per litre), pure NH_4HgCl was obtained.* André has also examined the pps. obtained by adding NH_4Aq and also NH_4ClAq to HgCl_2Aq in presence of KOH (*C. R.* 108, 1108, 1164). The pps. are compounds of NH_4HgCl , $\text{NH}_4\text{Hg}_2\text{OCl}$, and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ in varying proportions.

Properties.—A white solid, which volatilises completely, when strongly heated, without melting. Readily sol. in HClAq ; not blackened by NH_4Aq ; dissolved by acids, also by hot solutions of NH_3 salts.

Reactions.—1. When heated, in an open vessel, does not melt but yields a sublimate of HgCl and a mixture of 1 vol. N_2 and 2 vols. NH_3 ($6\text{NH}_4\text{HgCl} = 6\text{HgCl} + 4\text{NH}_3 + \text{N}_2$; Kane, *A. Ch.* [2] 72, 215). When slowly heated in a retort to c. 340° , HgCl_2 and NH_3 are given off, and a red crystalline compound, $2\text{NH}_4\text{Hg}_2\text{OCl.HgCl}_2$, remains.—2. Decomposed by water, slowly by cold, more rapidly by hot, eventually with formation of yellow mercurioxy-ammonium chloride, $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$, and NH_4Cl ($2\text{NH}_4\text{HgCl} + \text{H}_2\text{O} + \text{Aq} = (\text{NH}_4\text{Hg}_2\text{O})\text{Cl} + \text{NH}_4\text{ClAq}$).—3. Potash or soda separates $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ and evolves NH_3 . Only half the N of the original NH_4HgCl is evolved as NH_3 (Kane, *l.c.*); but by boiling for some days with KOH , renewed from time to time, all the N is removed as NH_3 , and HgO remains (Schmieder, *J. pr.* 75, 147). The fact that only half the N is readily evolved as NH_3 , by the action of alkalis on NH_4HgCl , has induced Rammelsberg (*J. pr.* [2] 38, 558) to regard this body as a compound of dimercurio-ammonium chloride and NH_4Cl , and to give it the formula $\text{NH}_4\text{HgCl.NH}_4\text{Cl}$. But it is to be remembered, as pointed out by Kane, that water readily separates NH_4HgCl into $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$ and NH_4Cl ; hence the NH_3 obtained by the action of aqueous alkali is probably due to the direct decomposition of NH_4Cl by the alkali.—4. Boiled with very dilute sulphuric acid till dissolved, the compound $\text{HgCl}_2.2\text{NH}_4\text{Cl}.2\text{H}_2\text{SO}_4$ forms on cooling (Kosman, *A. Ch.* [3] 27, 238).—5. Heated in dry hydrogen chloride, HgCl_2 and NH_4Cl are produced (Ullgren, *A.* 26, 203).—6. Heated with solutions of sodium chloride, potassium iodide, barium sulphide, &c., NH_3 is evolved and HgCl_2 , HgI_2 , HgS , &c., formed; e.g. $\text{NH}_4\text{HgCl} + 2\text{KIAq} + \text{H}_2\text{O} = \text{HgI}_2 + \text{KClAq} + \text{KOH} + \text{NH}_3$ (Kane, *l.c.*; Rammelsberg, *P.* 48, 182).—7. Boiled with ammonium chloride solution, mercurio-diammonium chloride $\text{N}_2\text{H}_4\text{Hg}_2\text{Cl}_2$ (*fusible white precipitate*) is produced.—8. Decomposed by heating with sulphur, with formation of a yellow sublimate of a chlorosulphide of N .—9. Rubbed with iodine and a little alcohol, HgI_2 is formed and then an explosion occurs, probably from production and decomposition of N iodide (Rice, *Ph.* [8] 6, 765; cf. Schwarzenbach, *B.* 8, 1231; Flückiger, *B.* 8, 619).—10. Bromine and chlorine cause evolution of N and formation of HgBr_2 or HgCl_2 (Schwarzenbach, *B.* 8, 1231).—11. Decomposed by alcoholic iodides, e.g. EtI (*v. Sonnenschein, A.* 101, 20).—12. For reaction with amylic mercaptan *v. Wagner, J. pr.* 53, 378.

Combinations.—1. Forms various compounds with NH_4HgCl and $(\text{NH}_4\text{Hg}_2\text{O})\text{Cl}$; obtained by adding NH_4Aq or NH_4ClAq to solutions of HgCl_2Aq containing KOH (André, *C. R.* 108, 1108, 1164).—2. Combines with HgCl_2 to form

$\text{NH}_4\text{HgCl}_2\text{HgCl}_2$; produced by slowly heating to $\text{c. } 340^\circ$ in a retort (Millon, *Z. Ch.* [8] 18, 892).

Mercuri-ammonium bromide, $(\text{NH}_4\text{Hg})\text{Br}$. (*Mercuri-bismamide, or amido-mercuric bromide* ($\text{Hg}(\text{NH}_2)_2\text{Br}$). *Dimercuri-diammonium bromide* ($\text{N}_2\text{H}_4\text{Hg}_2\text{Br}_2$.) A yellow powder, obtained by ppg. HgBr_2Aq with excess of NH_4Aq (cf. *Mercuri-ammonium chloride, supra*). Insol. water or alcohol, slowly changed by cold water, more quickly by hot water, to NH_4Br (Pesci, *G.* 19, 509). E. sol. NH_4Aq . Heated gives N , NH_3 , and HgBr ; when very slowly heated to $\text{c. } 340^\circ$ gives NH_3 , HgBr_2NH_3 , and $\text{NH}_4\text{Br.HgBr}$ (Mitscherlich, *J. pr.* 19, 455).

Series (ii). *Dimercuri-ammonium compounds*; NH_4X . According to Pesci (*G.* 19, 509) many and probably all the dimercuri-ammonium salts, when digested with NH_4Cl , NH_4Br , or NH_4I solution, evolve NH_3 in the proportion of 4NH_3 for each NH_4 group in the dimercuri-ammonium salt. This reaction may be applied to estimate dimercuri-ammonium salts, by conducting the digestion in a closed vessel containing a dish with a measured quantity of normal oxalic acid.

Dimercuri-ammonium hydroxide, NH_4OH . (*Mercurammonium hydroxide*). Prepared by saturating yellow HgO with NH_3 under increased pressure, finely powdering, and again saturating with NH_3 ; or by shaking HgO with alcoholic NH_3 for some hours and drying at ordinary temp. in NH_3 gas; the product, which is $\text{NH}_4\text{OH.H}_2\text{O}$, is then heated in dry NH_3 to $80^\circ\text{--}85^\circ$. The operation should be conducted in the dark (Weyl, *P.* 121, 601; 131, 539). A brown powder; explodes when strongly heated; decomposed by water, with evolution of NH_3 ; absorbs CO_2 from air, evolving NH_3 at the same time; dissolves in warm HClAq or HNO_3Aq with formation of salts of Hg and NH_4 .

Heated to 100° in absence of air, gives *dimmercuri-ammonium oxide* $(\text{NH}_4)_2\text{O}$. A dark-brown powder which explodes when heated, struck, or rubbed in a mortar; readily combines with water to form $\text{NH}_4\text{OH.H}_2\text{O}$; soluble in HClAq and HNO_3Aq ; reacts with HCl gas to form HgCl_2 and NH_4Cl . This oxide is also formed by the action of liquid NH_3 on HgO .

The *hydrate of dimercuri-ammonium hydroxide* $\text{NH}_4\text{OH.H}_2\text{O}$, is a yellow powder, obtained as described above. It appears to be isomeric with mercurioxy-ammonium hydroxide $(\text{NH}_2\text{Hg}_2\text{O})\text{OH}$ (p. 211).

Dimmercuri-ammonium chloride, NH_4Cl . (*Mercurammonium chloride*.) Obtained by treating the hydroxide (*v. supra*) with alcoholic solution of HCl ; also by treating the oxychloride formed by fusing together HgO and HgCl_2 in the ratio $3\text{HgO}:\text{HgCl}_2$, with liquid NH_3 , and removing excess of NH_3 by warming in a stream of dry air at 150° . Forms a yellow powder; decomposed suddenly at 300° to HgCl , Hg , and N (Weyl, *P.* 121, 601; 131, 539). Not acted on by boiling water; decomposed by hot KOHaq with production of NH_3 and HgO ; slowly dissolved by cold HClAq .

Forms a double compound with mercuric chloride $2\text{NH}_4\text{Cl.HgCl}_2$. (*dimmercuri-ammonium-mercuric chloride*). A red crystalline solid, resembling HgO , produced by very slowly

heating mercuri-ammonium chloride, NH_4HgCl , in a retort until HgCl begins to sublime. This compound reacts with hot HClAq to form NH_4Cl and HgCl_2 ; it is said to be unchanged by conc. HNO_3Aq , dilute $\text{H}_2\text{SO}_4\text{Aq}$, H_2O , or boiling alkali solutions (Mitscherlich, *J. pr.* 19, 458). Heated to 360° it separates into N , HgCl , and Hg .

Dimmercuri-ammonium bromide, NH_4Br . (*Mercurammonium bromide*.) Obtained by ppg. HgBr_2Aq by excess of NH_4Aq and digesting the pp. (NH_4HgBr) with water; better, by adding excess of NH_3 carbonate to HgBr_2Aq , washing the pp. of $4\text{NH}_4\text{Br} \cdot 5\text{NH}_3$ with NH_3 carbonate, warming with KOHaq , and washing with cold water (Pesci, *G.* 19, 509). Also obtained, according to Pesci, by the action of dilute HBrAq on Millon's base $(\text{NH}_4\text{Hg}_2\text{O})\text{OH}$. A yellow powder, insol. water, sol. HClAq , insol. HNO_3Aq ; decomposed by heat, without melting, yielding NH_3 and a sublimate which contains Hg (Pesci, *L.c.*). Digested for a short time with boiling NH_4BrAq , and filtered, small crystals of $\text{NH}_4\text{Br} \cdot 3\text{NH}_3$ are obtained. This compound seems similar to fusible white precipitate; it is described on p. 210 as *mercuri-diammonium bromide*. The double compound $4\text{NH}_4\text{Br} \cdot 5\text{NH}_3$ is obtained, in clear microscopic needles, by adding excess of NH_3 carbonate to HgBr_2Aq (Pesci, *L.c.*).

Dimmercuri-ammonium iodide, NH_4I , is obtained by the action of liquid NH_3 on the oxyiodide formed by fusing together HgO and HgI_2 in the ratio $3\text{HgO}:\text{HgI}_2$ (Weyl, *P.* 121, 601; 131, 539).

Dimmercuri-ammonium selenate, $(\text{NH}_4)_2\text{SeO}_4 \cdot 2\text{H}_2\text{O}$. A white pp. which darkens in light and is decomposed by heat; obtained by dissolving the basic selenate $\text{HgSeO}_4 \cdot 2\text{H}_2\text{O}$ in conc. NH_4Aq , and ppg. by much water (Cameron & Davy, *C. N.* 44, 63).

Series (iii). *Mercuri-diammonium compounds*; $\text{N}_2\text{H}_4\text{HgX}_2$.

Mercuri-diammonium chloride, $\text{N}_2\text{H}_4\text{HgCl}_2$. (*Mercurammonium chloride. Fusible white precipitate. Ammonio-mercuric chloride*, $\text{HgCl}_2 \cdot 2\text{NH}_3$.) Rammelsberg (*J. pr.* [2] 38, 558) regards this salt as a double compound of dimercuri-ammonium chloride— NH_4Cl —and NH_4Cl . He formulates it as $\text{NH}_4\text{Cl} \cdot 3\text{NH}_4\text{Cl}$ (*v. infra*).

When an alkali carbonate is added to HgCl_2Aq containing NH_4Cl , a white pp. is obtained; this pp. was called in pharmacy *mercurius precipitatus albus*, and for long was supposed to be the same as that formed by adding NH_4Aq to HgCl_2Aq . Wöhler (*P.* 26, 203) found that the pp. formed by alkali carbonate, in presence of sal-ammoniac, melted when heated, before volatilising, but that the pp. formed by ammonia volatilised without melting. The former pp. was then called *fusible white precipitate*, to distinguish it from the latter to which the name *infusible white precipitate* was given.

The researches of Krug (*Ar. Ph.* 42, 1) have shown that pure mercuri-diammonium chloride cannot be obtained by addition of alkali carbonate to HgCl_2Aq containing NH_4Cl at the ordinary temperature; the pp. consists of a mixture of mercuri-ammonium chloride (*infusible white precipitate*, NH_4HgCl) and mercuri-diam-

monium chloride (*fusible white precipitate*, $N_2H_4HgCl_2$); the longer the pp. remains in contact with the supernatant liquor, and the higher the temperature, the greater is the amount of *fusible white precipitate* formed. Krug found that almost pure NH_4HgCl (*infusible white precipitate*) was obtained by adding Na_2CO_3 aq to $HgCl_2$ aq mixed with NH_4Cl at 0° , and filtering at once (about $4Na_2CO_3:3HgCl_2:9NH_4Cl$). The first pp. formed by the alkali carbonate therefore probably always consists mostly of mercuri-ammonium chloride, NH_4HgCl , but this is acted on by the NH_4Cl present, and thus more or less $N_2H_4HgCl_2$ is produced; CO_2 is also given off from the alkali carbonate used, and this CO_2 , according to Krug's experiments, seems to change some of the NH_4HgCl to $HgCl_2 \cdot xHgO$ (with simultaneous formation of NH_4Cl and NH_4HCO_3), which oxychloride then probably reacts with NH_4Cl to produce $N_2H_4HgCl_2$.

Preparation.— $HgCl_2$ aq is dropped into boiling NH_4Cl aq containing NH_3 , as long as the pp. which forms is redissolved, and the liquid is allowed to cool. The compound crystallises out in garnet-red dodecahedra. Melts at $c. 300^\circ$ with decomposition.

Properties and Reactions.—Small red dodecahedra; also formed by ppn. with Na_2CO_3 as a white powder. Gently heated, gives off half its NH_3 , leaving $HgCl_2 \cdot NH_3$ (*v. infra*); melts at $c. 300^\circ$, evolving N and NH_3 and yielding a sublimate which reacts with water to form NH_4Cl , $HgCl_2$, and $HgCl$. Boiling water reacts to form mercurioxy-ammonium chloride, $(NH_4HgO)Cl$, and NH_4Cl . Alkalis evolve NH_3 . According to Rammelsberg (*J. pr.* [2] 38, 558) three-fourths of the N of mercuri-diammonium chloride is evolved by the action of hot alkali solution; hence R. assigns to this compound the formula $NH_4HgCl_3 \cdot NH_4Cl$; but as the action of boiling water on $N_2H_4HgCl_2$ is to produce $(NH_4HgO)Cl$ and NH_4Cl in the ratio $(NH_4HgO)Cl:3NH_4Cl$, it is easy to account for the action of boiling alkali without supposing fusible white precipitate to be a double compound of NH_4HgCl with NH_4Cl . Iodine reacts energetically; according to Flückiger (*B.* 8, 1619) the reaction is expressed thus $6(N_2H_4HgCl_2) + 2I_2 = N_2 + 6NH_4Cl + 4NH_3 + 2HgCl_2 + 2HgI_2 + 2HgCl$. Liquid ammonia dissolves $N_2H_4HgCl_2$; after prolonged action, and evaporation of the excess of NH_3 , a white crystalline mass remains which has the same composition as the original, according to Weyl (*P.* 1, 547).

Combination.—The compound $HgCl_2 \cdot NH_3$ may be regarded as a compound of $N_2H_4HgCl_2$ with $HgCl_2$ [$N_2H_4HgCl_2 \cdot HgCl_2 = 2(HgCl_2 \cdot NH_3)$]. This compound is formed by heating $HgCl_2$ in dry NH_3 , or by distilling HgO with NH_4Cl ; it melts when heated and distils without much change; it is decomposed by water, forming NH_4HgCl and $HgCl_2 \cdot NH_4Cl$ (Kane, *A. Ch.* [2] 72, 215).

Mercuri-diammonium bromide, $N_2H_4HgBr_2$. Small microscopic, rhombohedral, transparent crystals; obtained by adding excess of NH_3 carbonate to $HgBr_2$ aq, boiling the pp. of $4NH_4Br \cdot 5NH_3$ for a short time with NH_4Br aq, filtering, and allowing to cool (Pesci, *G.* 19, 509). Also formed by treating dimercuri-ammonium bromide ($NHgBr$) with boiling NH_4Br aq; by

the action of NH_4 aq on solution $HgBr_2 \cdot NH_3$, also by adding alcoholic NH_3 to $HgBr_2$ dissolved in alcohol (*P., l.c.*). Melts at $c. 180^\circ$ with evolution of NH_3 ; more strongly heated, yield two distinct sublimates. Easily sol. HCl aq, H_2SO_4 aq forms $HgBr_2$; alkalis produce $NHgBr$ (*P., l.c.*). Forms a compound with $HgBr_2$, viz. $N_2H_4HgBr_2 \cdot HgBr_2 (=HgBr_2 \cdot NH_3)$ similar to the chloro-compound already described (H. Rose, *P.* 20, 160).

Mercuri-diammonium sulphate, $N_2H_4HgSO_4 \cdot H_2O$. Lustrous, orthorhombic crystals. Obtained by adding, little by little yellow HgO to pure, saturated, cold $(NH_4)_2SO_4$ aq, each portion of HgO being allowed to dissolve before another portion is added, the liquid being kept cold; addition of HgO is continued till the liquid begins to grow turbid, the clear liquid is decanted and allowed to evaporate in the air or *in vacuo*. This compound is decomposed by the smallest quantity of water with production of a compound of mercurioxy-ammonium sulphate and mercuri-ammonium sulphate,

boiling water removes more H_2SO_4 , finally forming $(NH_4HgO)_2SO_4$ (*v. Mercurioxy-ammonium sulphate*, p. 211; cf. Millon, *A. Ch.* [3] 18, 410; Schmieder, *J. pr.* 75, 147). It is e. sol. in $(NH_4)_2SO_4$ aq, NH_4Cl aq, HCl aq, dilute H_2SO_4 aq, and HNO_3 aq; insol. conc. HNO_3 aq. Boiled with conc. H_2SO_4 , it gives $(NH_4)_2SO_4$ and $HgSO_4$; decomposed by KOH aq, forming a basic compound; with boiling conc. KOH aq, NH_3 is evolved and HgO formed. Heated to 115° water is evolved, and at a higher temperature complete decomposition results.

Mercuri-diammonium iodide, $N_2H_4HgI_2$; **Mercuri-diammonium fluoride**, $N_2H_4HgF_2$; and the double compound $N_2H_4HgI_2 \cdot HgI_2$, have been described (v. H. Rose, *P.* 20, 160; Nessler, *C. C.* 1856, 530; Finkener, *P.* 110, 147; Rammeisberg, *P.* 48, 170; Caillot a. Carriol, *J. Ph.* 9, 381).

Series (iv). Dimercuri-diammonium compounds; $N_2H_4Hg_2X_2$.

Dimercuri-diammonium sulphate, $N_2H_4Hg_2SO_4 \cdot H_2O (=SO_4 \cdot 2HgO \cdot 2NH_3)$. Obtained, according to Millon (*A. Ch.* [2] 18, 410), by saturating 70 c.c. cold conc. NH_3 aq with $HgSO_4$, allowing to stand in an atmosphere of NH_3 over CaO for some months, powdering the crystals which separate, and drying over CaO .

Series (v). Trimercuri-diammonium compounds; $N_2H_4Hg_3X_3$.

Trimercuri-diammonium sulphate, $N_2H_4Hg_3SO_4 \cdot 2H_2O (=SO_4 \cdot 3HgO \cdot 2NH_3)$. Prepared similarly to preceding salt, but using 90 c.c. NH_3 aq (Millon, *l.c.*).

Class III. MERBROXY-AMMONIUM COMPOUNDS ($NH_4HgO)X$.

The name *mercurioxy-* is here given to the group HgO , which is supposed to act as a dyad radicle in these compounds. The salts of this series may be regarded as *hydrated tetramercuri-diammonium compounds*; thus the carbonate $(NH_4HgO)_2CO_3$ may be written $N_2H_4 \cdot CO_3 \cdot 2H_2O$, and the chloride $(NH_4HgO)Cl$ may be written $N_2H_4 \cdot Cl \cdot 2H_2O$. Some of the salts of this series may also be regarded as hydrated *dimercuri-*

ammonium compounds; thus the chloride ($\text{NH}_2\text{Hg}_2\text{O}$)Cl loses water at 200° , and is therefore regarded by Rammelsberg as $\text{NHg}_2\text{Cl.H}_2\text{O}$.

Mercurioxy-ammonium hydroxide, $(\text{NH}_2\text{Hg}_2\text{O})\text{OH}$. (Millon's base.) This is the final product of the reaction of NH_2Aq on HgO ; the hydroxide contains H_2O . Millon gave the formula $\text{NH}_2\text{Hg}_2\text{O.OH.H}_2\text{O}$; Gerresheim, the formula $2(\text{NH}_2\text{Hg}_2\text{O.OH}).\text{H}_2\text{O}$ (A. 195, 373); and Rammelsberg, more recently (J. pr. [2] 38, 558), assigns the composition $3(\text{NH}_2\text{Hg}_2\text{O.OH}).2\text{H}_2\text{O}$. The empirical formula for the base is $2\text{HgO.NH}_2.\text{H}_2\text{O}$.

Preparation.—Yellow HgO is agitated with NH_2Aq , quite free from carbonate, so long as any change occurs; if red HgO is used the change is not completed for some days. The yellow-brown product is washed with cold water, crystallised from hot water, and dried (Millon, A. Ch. [3] 18, 392).

Properties.—Yellow, microscopic crystals, probably rhombic. Appears to be isomeric with hydrated dimercuri-ammonium hydroxide $\text{NHg}_2\text{OH.H}_2\text{O}$ (p. 209). Insol. alcohol or ether; somewhat sol. water. S. $\cdot 007$ at 17° , $\cdot 06$ at 80° . Acts as a very strong base; decomposes NH_4 salts energetically with evolution of NH_3 , and rapidly combines with CO_2 when exposed to air. Several salts may be obtained by dissolving the base in excess of acetic acid, and ppg. by alkali permanganate, chromate, &c. Over H_2SO_4 loses H_2O and becomes brown; heated to 130° further loses $\frac{1}{2}\text{H}_2\text{O}$, leaving *mercurioxy-ammonium oxide* $(\text{NH}_2\text{Hg}_2\text{O})_2\text{O}$.

Reactions.—1. The hydrated base is very slowly decomposed by boiling alkali solution; the dehydrated base is only decomposed by molten alkali.—2. Decomposes *ammonium salts* rapidly, with evolution of NH_3 .—3. Combines so rapidly with carbon dioxide that it is almost impossible to obtain the base quite free from carbonate.—4. With acids forms salts $(\text{NH}_2\text{Hg}_2\text{O})\text{X}$ ($\text{X} = \text{NO}_3, \text{SO}_4$, &c.) (v. Rammelsberg, J. pr. [2] 38, 558).—5. Decomposed by heat with more or less explosion (Millon, l.c.; cf. Hirzel, J. 1852, 419; 1853, 381).—6. Many salts, e.g. sulphates and chlorides, are decomposed by shaking with Millon's base, with complete removal of the acid of the salt used (v. Gerresheim, A. 195, 373).—7. Heated with ethylic iodide to 100° yields crystals of 2NEt.I.3HgI_2 ; ethylic bromide reacts similarly.—8. A thiocarbonate of the base is obtained by heating with carbon disulphide (Gerresheim, l.c.).

Mercurioxy-ammonium chloride, $(\text{NH}_2\text{Hg}_2\text{O})\text{Cl}$. (Hydrated tetramercurammonium chloride $\text{N}_2\text{Hg}_4\text{Cl}_2.2\text{H}_2\text{O}$. Hydrated dimercuri-ammonium chloride $\text{NHg}_2\text{Cl.H}_2\text{O}$.) This compound is formed by the reaction of boiling water with either fusible white pp. $\text{N}_2\text{H}_2\text{Hg}_2\text{Cl}_2$, or infusible white pp. $\text{NH}_2\text{Hg}_2\text{Cl}$. It is also produced by passing dry NH_3 over the oxychloride 3HgO.HgCl_2 at 150° (Ullgren, P. 42, 395). A heavy, yellow powder; v. sl. sol. water; e. sol. HClAq and HNO_3Aq (Kane, P. 42, 367). Decomposed by heat, giving NH_3 , N , H_2O , HgCl , and Hg . Decomposed by excess of solutions of KCl , NaCl , and KI , with evolution of NH_3 . Loses water at 200° , and is therefore regarded by Rammelsberg as $\text{NHg}_2\text{Cl.H}_2\text{O}$ (J. pr. [2] 38, 558).

Mercurioxy-ammonium chloride combines with $\text{NH}_2\text{Hg}_2\text{Cl}$ and NHg_2Cl to form various double compounds, e.g.,

these compounds were obtained by André by ppg. HgCl_2Aq with NH_2Aq , some of them requiring the presence of KOH for their production (C. R. 108, 233, 290, 1108, 1164).

Mercurioxy-ammonium iodide, $(\text{NH}_2\text{Hg}_2\text{O})\text{I}$. (Hydrated tetramercurammonium iodide $\text{N}_2\text{Hg}_4\text{I}_2.2\text{H}_2\text{O}$. Hydrated dimercuri-ammonium iodide $\text{NHg}_2\text{I.H}_2\text{O}$.) This compound is formed by adding NH_2Aq to Nessler's reagent (alkaline solution of HgI_2 in KI Aq); the composition of the pp. thus produced is often represented as $\text{Hg.NH}_2\text{I} + \text{HgO}$, or as $\text{Hg.NHg}_2\text{I} + \text{H}_2\text{O}$. The compound is best prepared by dissolving $\text{HgI}_2.2\text{KI}$ in KOH Aq , adding NH_2Aq , washing thoroughly with cold water, and drying at 100° ($2\text{K}_2\text{HgI}_4\text{Aq} + 3\text{KOH Aq} + \text{NH}_2\text{Aq} = (\text{NH}_2\text{Hg}_2\text{O})\text{I} + 7\text{KIAq} + 2\text{H}_2\text{O}$;

v. Rammelsberg, P. 48, 170). $(\text{NH}_2\text{Hg}_2\text{O})\text{I}$ is also formed by heating 3IHgO.HgI_2 to 180° in NH_3 (Rammelsberg); and by boiling HgI_2 with excess of conc. NH_2Aq .

Mercurioxy-ammonium iodide is a brown powder with a purple-red tint. Begins to give off water at 128° ; heated more highly, out of contact with air, it melts to a dark-brown liquid, and then decomposes violently, giving H_2O , Hg , HgI_2 , NH_3 , and N . Sol. warm KIAq , with formation of K_2HgI_4 and KOH and evolution of NH_3 . Sol. warm HClAq ; HgI_2 and HgCl_2 are deposited on cooling (Rammelsberg). Decomposed by hot BaSAq , with evolution of all N as NH_3 . Heated in HCl gas, gives a sublimate of HgCl_2 , NH_4Cl , NH_4I , and $(\text{NH}_4)_2\text{HgI}_4$.

Mercurioxy-ammonium nitrates. Several nitrates, and some double nitrates, of the mercurioxy-ammonium compounds seem to exist.

The salt often called *Soubeiran's ammoniacal salt* is probably the *normal nitrate* $(\text{NH}_2\text{Hg}_2\text{O})\text{NO}_3$ (Soubeiran, J. Ph. 12, 465). This compound is obtained by ppg. dilute $\text{Hg}(\text{NO}_3)_2\text{Aq}$, containing only a little free acid, with very dilute NH_2Aq , boiling with water till the pp. becomes compact and curdy, washing, and drying.

The loose flocculent pp. produced by adding very dilute NH_2Aq to dilute $\text{Hg}(\text{NO}_3)_2\text{Aq}$, sometimes known as *Mitscherlich's ammoniacal salt*, is probably a *double compound of mercurioxy-ammonium nitrate and mercuri-ammonium nitrate*, $(\text{NH}_2\text{Hg}_2\text{O})\text{NO}_3.(\text{NH}_2\text{Hg})\text{NO}_3.\text{H}_2\text{O}$.

Other compounds are obtained by boiling Mitscherlich's salt with excess of NH_2Aq with addition of $\text{NH}_4\text{NO}_3\text{Aq}$, and by dissolving Soubeiran's salt in hot conc. $\text{NH}_4\text{NO}_3\text{Aq}$; the salts thus formed are probably *double compounds of mercurioxy-ammonium nitrate and ammonium nitrate*, but their exact composition and constitution are not yet decided (v. Mitscherlich, P. 9, 387; 16, 41; Millon, A. Ch. [3] 18, 392; Kane, A. Ch. [2] 72, 215; Nessler, J. 1856, 409).

Mercurioxy-ammonium sulphate, $(\text{NH}_2\text{Hg}_2\text{O})\text{SO}_4$. (Hydrated tetramercurammonium sulphate, $\text{N}_2\text{Hg}_4\text{SO}_4.2\text{H}_2\text{O}$. Hydrated dimercuri-ammonium sulphate.

(NH_4)₂SO₄·2H₂O. *Ammoniacal turpethum*). Obtained by saturating conc. NH_4Aq with HgSO_4 , and allowing to evaporate in air, or over H_2SO_4 ; also by digesting the basic sulphate $\text{HgSO}_4\cdot\text{HgO}$ (*mineral turpethum*) with NH_4Aq ; also by digesting HgO with hot (NH_4)₂SO₄ (Millon, *A. Ch.* [3] 18, 392; Ullgren, *P.* 42, 395; Hirzel, *J.* 1852. 419; 1853. 381). Schmieder (*J. pr.* 76, 147) obtained the salt by repeatedly treating mercuri-diammonium sulphate, $\text{N}_2\text{H}_4\cdot\text{Hg}\cdot\text{SO}_4\cdot\text{H}_2\text{O}$ (v. p. 210), with boiling water, till the filtrate was free from sulphates. Forms a heavy yellow-white powder; sl. sol. water; easily sol. HClAq or HNO_3Aq . Decomposed by heat to H_2O , N , NH_3 , and Hg_2SO_4 . Treated with KOH Aq , gives NH_3 and a *basic salt* ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{SO}_4\cdot\text{HgO}$ (perhaps $\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{SO}_4$); and on further treatment with KOH Aq yields NH_3 , HgO , and K_2SO_4 .

Besides the mercurioxy-ammonium salts described above, the following have been prepared:—

Mercurioxy-ammonium bromate ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{BrO}_3$ (Rammelsberg, *P.* 55, 82).

Mercurioxy-ammonium carbonate ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{CO}_3$ (Millon, *A. Ch.* [3] 18, 392; Hirzel, *J.* 1852. 419; 1853. 381).

Mercurioxy-ammonium chromate ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{CrO}_4$; and a *double basic salt* ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{CrO}_4\cdot 3\text{HgCrO}_4\cdot\text{HgO}$ (Hirzel, *l.c.*).

Acid mercurioxy-ammonium fluoride ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{F}\cdot\text{HF}$ (Finkener, *P.* 110, 632).

Mercurioxy-ammonium-ammonium iodate ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{IO}_3\cdot 2\text{NH}_4\cdot\text{IO}_3$ (Millon, *A. Ch.* [3] 18, 410).

Mercurioxy-ammonium-mercuric phosphate ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{Hg}\cdot\text{PO}_4$ (Hirzel, *J.* 1852. 419; 1853. 381).

Mercurioxy-ammonium-mercuric sulphite ($\text{NH}_4\cdot\text{Hg}_2\text{O}\cdot\text{SO}_3\cdot\text{HgSO}_3$ (Hirzel, *l.c.*).
M. M. P. M.

MERCURIALINE. The volatile base obtained by distilling the seeds of *Mercurialis annua* or *M. perennis* with lime and water, and formerly called 'mercurialine,' is identical with methylamine (E. Schmidt, *B.* 10, 2226; *A.* 193, 73; cf. Reichardt, *J. pr.* 104, 301).

MERCURY. (*Quicksilver*.) Hg . At. w. 199.8. Mol. w. 199.8. [-38.5°] (Regnault, *Acad.* 26, 525). [-38.5°] (Mallet, *P. M.* [5] 4, 145). (357.25° at 760 mm.) (Regnault, *l.c.*; for table of B.P. of Hg at pressures from 123 to 798 mm. v. Ramsay & Young, *O. J.* 47, 656). S.G. $^{20^\circ}$ 13.5958 to 13.596 (Regnault); $^{20^\circ}$ 13.546 (Volkman, *W.* 13, 209; a very full table of S.G. and volume of Hg from 0° to 360° is given). S.G. solid Hg , $^{-35.5^\circ}$ = 14.1982 (Mallet, *P. M.* [5] 4, 145). V.D. 99.8 at 440° to 1565° (V. Meyer, *B.* 12, 1426). S.H. .03312 from 20° to 50° , .03278 from 25° to 142° (Winkelmänn, *P.* 159, 152; v. also Pettersson, *B.* 13, 1715). S.H.P. $^{275^\circ}$ to 356° = 1.666 (Kundt & Warburg, *P.* 157, 353; experimentally determined). C.E. .00018153 from 0° to 100° (Regnault, *Acad.* 21, 271; v. also Willner, *P.* 153, 440). T.C. (Ag =100) 5.8 (Calvert & Johnson, *P. M.* [4] 16, 881; cf. Weber, *W.* 10, 490). E.C. c. 1.96 (Cu =100). For electrical resistance of Hg v.

Kohlrausch, *W.* 35, 400; (cf. Grunmach, *W.* 37, 508). For table of vapour-pressure of Hg from 135° to 520° v. Ramsay & Young, *O. J.* 49, 37. Heat required to change 200 grm. Hg at 358° to gas = 12,400 gram-calories; heat required to melt 200 grm. solid Hg = 564 (Person, *A. Ch.* [3] 24, 257; *ibid.* 21, 295). Chief lines in emission-spectrum 6151, 5460.5, 4358 (Thalén, 1868; for table of lines of high refrangibility v. Hartley & Adeney, *T.* 1884. 186). S.V.S. c. 14. Crystallises in regular octahedra.

Occurrence.—Small quantities of Hg are found as globules disseminated through ores of Hg , or in the rocks in which these ores occur. The chief ore of Hg is *cinnabar*, HgS , found in limited quantities in Illyria, Spain, Bohemia, Peru, China, California, the Ural, and one or two other localities. An amalgam of Hg and Ag is sometimes found native; iodide, chloride, and minute quantities of selenide, of Hg are also known to occur.

Preparation.—1. By distilling cinnabar in a regulated supply of air, condensing the Hg in a suitable apparatus, and allowing the SO_2 to escape.—2. By heating cinnabar with lime; CaS and CaSO_4 are formed, and the Hg distils and is condensed.—3. By heating cinnabar with iron (smithy-scales), Hg , FeS , and SO_2 are produced; the Hg is condensed in long chambers, or by downward distillation in a trough filled with water.

To purify Hg from dust, &c., it may be filtered through a paper cone having a minute hole at the apex, or pressed through leather. Traces of metals in solution may be removed by leaving the Hg in contact with cold conc. H_2SO_4 for some weeks, with frequent agitation, and then digesting with very dilute HNO_3Aq , or with HgNO_3Aq (Branchi, *R. P.* 6, 77; Wittstein, *R. P.* 65, 362). Karsten and Ulex (*A.* 60, 210) recommend to rub the Hg in a basin for ten minutes, with 1.60th of its weight of FeCl_3Aq , S.G. 1.48 diluted with an equal weight of water, to pour off the liquid, which contains the foreign metals and some HgCl_2 , to wash with water, and then to dry the Hg by heating it. L. Meyer (*B.* 12, 437) has described a convenient apparatus for purifying Hg by bringing a fine stream of it into contact with FeCl_3Aq . Brühl (*B.* 12, 304) shakes Hg with an equal volume of chromate solution, made by dissolving 5 grams $\text{K}_2\text{Cr}_2\text{O}_7$ in 1 litre water, and adding a few c.c. of H_2SO_4 ; the shaking is continued until the red HgCrO_4 , at first produced has disappeared, and the liquid is coloured green by $\text{Cr}_2(\text{SO}_4)_3$; the fine greyish powder which is formed, and which consists of oxides of foreign metals, is washed away by a rapid stream of water. The process is repeated, and the Hg is then shaken with pure water until no more greyish powder is formed. About half p.c. of Hg is lost. Crafts (*B.* [2] 49, 856) removes Pb , Zn , Sn , and most other metallic impurities from Hg by placing the Hg in a slightly inclined glass tube, and aspirating a gentle current of air through the apparatus for about forty-eight hours. The oxides of the foreign metals collect at the top. Ag cannot be removed by this method.

Pure Hg may be obtained by distilling equal parts of cinnabar and burnt lime or Fe filings. Also by boiling pure HgCl_2Aq with pure Fe .

Also by heating HgO in a retort, and digesting the residual Hg , which contains a little HgO , with dilute HNO_3 or H_2SO_4 . Millon (*B. J.* 27, 110) prepares HgO (from which to make Hg) by shaking Hg for some time with dilute HNO_3 to remove foreign metals, washing, dissolving in such a quantity of HNO_3 that 1-10th of the Hg remains undissolved, evaporating to dryness, and heating.

After purifying Hg by one of the foregoing methods it is advisable to distil it. A very convenient apparatus for distilling Hg under reduced pressure is described by Wright (*Am. S.* [3] 22, 479; v. also Weber, *Carl. Rep.* 15, 52; Weinhold, *Carl. Rep.* 15, 1).

Properties.—A very lustrous metal, white, with the slightest tinge of blue. Exists as a very mobile liquid at ordinary temperatures, and does not solidify above -88.5° . Hg boils at 360° , but it is very easily volatilised; even at -18° sufficient Hg is vaporised to produce a daguerreotype by twenty-four hours' exposure (Regnault, *C. R.* 78, 1462). According to Merget (*C. R.* 78, 1886) solid Hg at -44° is very slowly vaporised. Solid Hg is a tin-white, ductile mass of octahedral and needle-shaped crystals. It may be cut with a knife. Hg is a very coherent liquid. By trituration with sugar, grease, sulphur, chalk, &c., or by agitation with ether, turpentine, and some other liquids, Hg appears as a grey powder, which consists of minute globules of Hg separated by the foreign matter present (*extinction or deadening of mercury*). Finely-divided Hg is also obtained by mixing about equal parts of SnCl_2 , dissolved in HClAq , and HgCl_2 , dissolved in hot water ($\text{SnCl}_2\text{Aq} + \text{HgCl}_2\text{Aq} = \text{SnCl}_4\text{Aq} + \text{Hg}$). In this state of fine division, Hg is slowly oxidised by contact with air. Pure Hg adheres very slightly to glass. When foreign metals are present the Hg leaves a blackish film on glass. A globule of pure Hg should roll down a slightly inclined surface without losing its round form, and without leaving any streak behind it. When shaken in a bottle with dry air it should not form any black powder.

Pure Hg is not oxidised by exposure to air at ordinary temperatures; when heated to near its B.P., HgO is slowly formed. (Berthelot (*C. R.* 91, 871) asserts that pure Hg is very slightly oxidised in air). Hg obtained in a state of fine division by trituration, e.g. with chalk, is slowly oxidised at the ordinary temperature. Ozone oxidises Hg at ordinary temperatures (Volta, *G.* 9, 621; cf. *Reactions*, No. 2). Hg combines directly with O, S, and the halogens; it alloys with most of the metals, in some cases forming definite compounds (v. *Mercury, amalgams of*). Hg reacts with hot conc. H_2SO_4 to produce HgSO_4 and SO_2 ; with HNO_3 it produces HgNO_3 , $\text{Hg(NO}_3)_2$, or a basic nitrate, according to the temperature and the quantity of acid. HClAq does not react with Hg .

The atomic weight of Hg has been determined (1) by analysing HgO (Sefström, *S.* 22, 328; Turner, *A.* 13, 18; Erdmann a. Marchand, *J.* pr. 81, 395); (2) by determining Cl in HgCl_2 and HgCl (Turner, *La.*; Svanberg, *J.* pr. 45, 468; Millon, *A. Ch.* [3] 18, 846); (3) by estimating Hg in HgS (Erdmann a. Marchand, *J.* pr. 81, 400); (4) by determining S.H. of Hg .

Hg is distinctly a metallic element. It forms salts by replacing the H of most acids. These salts belong to two series, HgX and HgX_2 , where $\text{X} = \text{NO}_3$, ClO_4 , HSO_4 , H_2PO_4 , &c. Both series are well represented by definite and stable salts. HgO dissolves in molten KOH , and crystals of $\text{K}_2\text{O.HgO}$ are obtained on cooling. The compound $\text{Na}_2\text{O.HgO}$ is said also to exist. HgS dissolves in NaHSaAq and conc. KHSaAq . The compound $\text{K}_2\text{S.HgS.5H}_2\text{O}$ has been isolated. The existence of these compounds shows that HgO and HgS are slightly acidic towards K_2O and KHS .

The molecular weight of Hg has been directly determined; the molecule is monatomic. The atom of Hg is divalent in the gaseous molecules HgCl_2 , HgBr_2 , and HgI_2 . The molecular formula of calomel is probably HgCl ; if this is so, the atom of Hg is monovalent in this molecule.

Hg is related to Mg and Zn , and more distantly to Be , Ca , Sr , and Ba (v. **MAGNESIUM GROUP OF ELEMENTS**, p. 165; and cf. **CLASSIFICATION**, vol. ii. pp. 204, 207).

Reactions.—1. Heated in air or oxygen, to near its B.P., Hg slowly forms HgO .—2. Ozone produces some HgO at ordinary temperatures; perfectly dry ozone does not react with dry Hg (Shenstone a. Cundall, *C. J.* 51, 619).—3. Hg is oxidised by agitation with solution of *potassium permanganate*; Hg_2O is formed if the solution is cold, and HgO if hot (Kirchmann, *Ar. Ph.* [2] 150, 203).—4. Hg does not react with *hydrochloric acid*.—5. *Sulphuric acid*, when hot and conc., forms HgSO_4 , or Hg_2SO_4 if there be an excess of Hg and the acid is not very hot, and SO_2 ; dilute H_2SO_4 scarcely acts on Hg .—6. *Nitric acid*, cold and dilute, forms HgNO_3 ; with hot HNO_3 and excess of Hg , basic mercurous nitrates, $x\text{Hg}_2\text{O.yN}_2\text{O}_5$, are formed; excess of hot HNO_3 produces $\text{Hg(NO}_3)_2$.—7. Warm conc. *hydrobromic* and *hydriodic acids* produce HgBr_2 and HgI_2 , respectively (cf. *Berthelot*, *A. Ch.* [5] 16, 433).—8. *Hydrogen sulphide*, or *alkaline polysulphides*, produce HgS .—9. With *nitrogen tetroxide*, forms HgNO_3 and NO (Ramsay, *B.* 18, 3154).

Combinations.—1. Hg combines with the *halogens*, forming HgX or HgX_2 , according to the relative quantities of the reacting bodies.—2. With *oxygen*, Hg forms Hg_2O and HgO .—3. With *sulphur* and *selenium*, HgS and HgSe are produced.—4. Hg probably combines with *phosphorus*, but no definite compound has been isolated with certainty.

Detection and Estimation.—Solid Hg compounds are decomposed by drying, mixing well with dry Na_2CO_3 , and heating strongly in a small tube closed at one end; Hg is volatilised, and condenses on the cold part of the tube in minute globules. Mercurous salts in solution give a white pp. (HgCl) with HClAq , or a soluble chloride; this pp. is blackened by NH_3Aq with formation of NH_2HgCl . Mercurous salts are oxidised to mercuric salts by boiling with HNO_3Aq . Mercuric salts are not pptd. by HClAq . H_2SAq , or a soluble sulphide, ppts. black HgS ; addition of a small quantity of the reagent causes the formation of a compound of HgS with the original salt present; this pp. is white, yellow, or brown, according to the quantity of reagent used.

Hg is sometimes estimated by heating its dry compounds with powdered CaO, condensing the Hg under water, transferring to a weighed crucible, drying by blotting paper and then over H_2SO_4 ; the metal is sometimes p.p.d. by SnCl_2 or H_3PO_4 at c. 60° , dried, and weighed. Hg is also estimated as HgCl_2 by adding HClAq , then nearly neutralising with KOH Aq , adding K or Na formate, digesting for some days at 60° - 70° (Hg is p.p.d. at boiling temperature), collecting the HgCl_2 on a weighed filter, washing, drying at a low temperature and weighing. Hg is also determined as HgS , by p.p.n. from HgCl_2Aq by H_2S , and collection on a weighed filter. If the pp. is formed from solutions containing HNO_3Aq or FeCl_3Aq &c., free S is p.p.d. with the HgS ; the pp. may then be heated with CaO and the Hg collected, or heated in Cl, the HgCl_2 passed into water, and Hg p.p.d. by SnCl_2 . Hg may also be determined by depositing it by electrolysis on a weighed Pt dish. A mercurous salt, in presence of mercuric, may be estimated by p.p.g. by HClAq , from a cold very dilute solution, not more than a very small quantity of HNO_3 being present.

There are several methods for the volumetric determination of Hg; that described by Hannay, which is based on the fact that the turbidity produced in mercuric salt solutions by a few drops of NH_3Aq is removed by a definite quantity of KCN Aq , is said to give satisfactory results. (For details of the methods v. *Manuals of Analysis*.)

Mercury, alloys of; v. next line.

Mercury, amalgams of. The alloys of Hg are usually called *amalgams*; the word is supposed to be an alchemist's anagram of $\mu\lambda\alpha\gamma\mu\alpha$ = a soft mass. Amalgams are known of most of those metals which have been fairly well studied. Amalgams are formed by mixing the other metal with Hg, by p.p.g. the other metal on Hg (or Hg on the other metal), and by placing the other metal in contact with Hg and a dilute acid. Many amalgams are definite compounds, others seem to be merely solutions of metals in Hg, and others are probably solutions of definite compounds in excess of Hg. Amalgams of Bi, Pb, Sn, and Zn, for instance, retain Hg at 360° (B.P. of Hg), but not at 410° . Crystalline amalgams of K and Na, K_2Hg and Na_2Hg , are obtained by heating solutions of K and Na in Hg to 440° .

The best-known amalgams are those of Al, Ba, Bi, Cd, Cs, Ca, Cr, Co, Cu, Ag, Fe, Pb, Mg, Mn, Ni, Os, Pd, Pt, K, Ag, Na, Sr, Ti, Sn, and Zn. For brief accounts of these amalgams, with the exception of those of Cu which are described below, v. the various metals, *ALUMINIUM*, *BARIUM*, &c.; the articles, *AMALGAMS*, vol. i. p. 149, and *ALLOYS*, vol. i. p. 132, should be consulted. An interesting paper on *Amalgams*, by Dudley, will be found in *Proc. Amer. Ass. for Advancement of Science*, 1890, 145.

COPPER AMALGAMS (should have been described under *COPPER, ALLOYS OF*, vol. ii. p. 254). Amalgams of Cu are formed by placing Cu foil in HgNO_3Aq , by triturating 3 parts Hg with a mixture of 1 part very finely divided Cu and a few drops of HgNO_3Aq , by triturating Hg with NaCl and verdigris, by making Hg the negative electrode during electrolysis of CuSO_4Aq , by immersing Na-amalgam, or Zn-amalgam, in

CuSO_4Aq , and in some other ways. By dissolving Cu in Hg, and removing excess of Hg by pressure, Joule obtained an amalgam having the composition CuHg (*Chem. Gazette*, 1850, 339). By heating amalgams rich in Hg, De Souza obtained Cu_2Hg at c. 410° , and Cu_3Hg at c. 360° (B. 9, 1050). By p.p.g. Cu from CuSO_4Aq by Fe, washing well, moistening with HgNO_3Aq , and rubbing with Hg, amalgams are obtained which harden after a time. The amalgam with from 25 to 33 p.c. Cu, may be obtained soft and plastic by heating nearly to 360° , and kneading for some time in a warm mortar; this amalgam slowly hardens without either contracting or expanding; it is used for stopping teeth (v. Von Gerabeim, A. 70, 344).

Mercury, ammonio-compounds of; v. *MERCURAMMONIUM COMPOUNDS*, p. 206.

Mercury, autimonates of; v. vol. i. pp. 285-6.

Mercury, autimonide of. A substance of the nature of an amalgam is formed by triturating together Sb and Hg; little is known of its composition and properties; it is very easily decomposed.

Mercury, arsenates of; v. vol. i. p. 309.

Mercury, arsenide of. Bergmann obtained what he thought was a compound of 1 pt. As with 5 pts. Hg by heating Hg and As together.

Mercury, arsenites of; v. vol. i. p. 306.

Mercury, bromides of. Two bromides of Hg are known, HgBr and HgBr_2 . Mercuric bromide has been vaporised; its mol. w. is $359.3 = \text{HgBr}_2$. Mercurous bromide has also been vaporised; the results indicate the mol. w. $279.55 = \text{HgBr}$; but it is not certain whether partial dissociation into HgBr , and Hg occurred during vaporisation (v. *infra*; also *Mercurous chloride*, p. 215). Both HgBr and HgBr_2 form double compounds with the bromides of metals more positive than Hg.

MERCUROUS BROMIDE. HgBr (*Mercury proto- or mono-bromide*). Mol. w. 279.55 (?). H.F. [HgBr] = 25,475 (Thomsen, Z. P. C. 2, 21).

Preparation.—1. By subliming an intimate mixture of 80 pts. Br and 200 pts. Hg.—2. By adding KBrAq to HgNO_3Aq .—3. By heating saturated HgNO_3Aq , as free as possible from HgO and slightly acidified with HNO_3Aq , with Br, decanting, and allowing to cool in the dark (Stroman, B. 20, 2818).—4. By adding alcoholic solution of Br to cold conc. HgNO_3Aq (Stroman, l.c.).

Properties and Reactions.—As prepared by method 3 (*supra*), forms small, white, nacreous, tetragonal, scales; prepared by method 2, appears as yellow, crystalline, spangles (Stroman, l.c.). S.G. 7.307 (Karsten, S. 65, 894). Sublimes at 340° - 350° . Melts c. 405° (?) (Carnelley, C. J. 33, 277). V.D. 146.3 according to Mitscherlich (P. 29, 193). Tasteless and odourless. Insol. in water. Hot conc. H_2SO_4 dissolves HgBr with evolution of SO_2 ; dissolves slowly in hot HNO_3Aq S.G. 1.42; decomposed by hot HClAq dil. or conc.; decomposed by NH_3Aq or KOH Aq , forming NH_4Br or KBr , and leaving a black residue which contains Hg (Stroman, l.c.). Slowly decomposed by boiling K_2CrAq , giving HgBr_2 and Hg. Soluble in some 'NL' salt solutions.

Combinations.—Two compounds with *strontium chloride* are described by Löwig (P. 14, 485). By dissolving HgBr in boiling SrBr_2Aq , allowing

to cool, pouring off from separated HgBr_2 , and evaporating, crystals of $6\text{HgBr}_2\cdot\text{SrBr}_2$ separate; by dissolving these crystals in water, filtering from HgBr_2 , which separates, and evaporating, a very soluble crystalline compound $2\text{HgBr}_2\cdot\text{SrBr}_2$ is obtained.

MERCURIC BROMIDE. HgBr_2 (Dibromide of Mercury). Mol. w. 359.3. H.F. [HgBr_2] = 41,880 (Thomsen, *Z. P. C.* 2, 21).

Preparation.—1. By dissolving HgO in HBrAq , and crystallising.—2. By bringing Hg into slight excess of Br , warming to remove uncombined Br , and subliming.—3. By heating an intimate mixture of HgSO_4 with rather more than its own weight of KBr ; the HgBr_2 , which sublimes is said to contain HgBr .—4. By adding KBrAq to $\text{Hg}(\text{NO}_3)_2\text{Aq}$, evaporating as long as HgBr_2 crystallises out, and crystallising from alcohol.—5. By agitating Hg with water, adding Br as long as its colour is removed, boiling, filtering, allowing to crystallise, and drying at $c. 150^\circ$.—6. By adding excess of Br to a slightly acid solution (S.G. 1.197) of $\text{Hg}(\text{NO}_3)_2$; HBrOAq is formed in the reaction (Sievers, *B.* 21, 647).

Properties.—White rhombic prisms, isomorphous with HgCl_2 ; $\alpha:b:c = 6817:1:9975$ (Hjorthal, *Z. K.* 3, 362). S.G. 5.9202 (Karsten, *S.* 65, 894), 5.7298 at 16° , 5.7461 at 18° (Clarke's *Specific Gravity Tables*, new ed. 82). V.D. 175.5, Mitscherlich (*P.* 29, 193). Melts at 244° (Carnelley a. Williams, *C. J.* 37, 127). Can be sublimed unchanged. S. 1.06 at 9° , 20–25 at 100° (Lassaigne). Very sol. in alcohol and ether. HgBr_2Aq reddens litmus.

Reactions.—1. Heated with phosphorus, arsenic or antimony, forms bromide of P, As, or Sb.—2. Decomposed, yielding HgBr , by sunlight, or contact with copper or mercury, or by mixing with cuprous bromide dissolved in HBrAq .—3. HgBr_2Aq with ammonia gives a white pp. of HgBrNH_2 (Mitscherlich, *J. pr.* 19, 455).—4. With sodium hypochlorite, HgBr_2Aq gives oxychlorides $\alpha\text{HgO}\cdot\gamma\text{HgCl}_2$ (Rønnelsberg).—5. With hypochlorous acid, HgCl_2 and $\text{Hg}(\text{BrO}_3)_2$ are formed (Balard).—6. Decomposed by nitric or sulphuric acid, giving off Br .—7. Oxybromides, $\alpha\text{HgO}\cdot\gamma\text{HgBr}_2$, are obtained by boiling HgBr_2Aq with mercuric oxide.—8. Mixed with mercuric iodide and crystallised from ether or acetone, HgI_2Br is obtained; this compound is also formed by the action of an alkyl iodide, e.g. EtI , on HgBr_2 , dissolved in acetone (Oppenheim, *B.* 2, 671) (*v. Mercury, iodobromide of p.* 221).

Combinations.—1. With hydrobromic acid to form bromomercuric acid HHgBr_2 (*v. infra*).—2. Combines with many bromides of more positive metals than Hg , to form salts regarded by Von Bonsdorff as bromomercurates (*P.* 19, 839). These salts are obtained by evaporating solutions of the component bromides; the more important are $\text{HgBr}_2\cdot\text{KBr}$ and $\text{HgBr}_2\cdot 2\text{KBr}$; $\text{HgBr}_2\cdot\text{MgBr}_2$, and $2\text{HgBr}_2\cdot\text{MgBr}_2$; $\text{HgBr}_2\cdot\text{SrBr}_2$, and $2\text{HgBr}_2\cdot\text{SrBr}_2$ (Löwig, *P.* 14, 485). Salts containing NaBr , CaBr_2 , BaBr_2 , and ZnBr_2 were also obtained by Von Bonsdorff (*loc.*). Bromomercuric acid, HHgBr_2 , was obtained by Neumann (*M.* 10, 236), in long transparent needles, by slightly warming excess of HgBr_2 with HBrAq , filtering through asbestos, and cooling to between 0° and -4° . This acid is

readily decomposed by moisture or heat. Solution of HgBr_2 in HBrAq reacts with alkalis to give $\text{HgBr}_2\cdot 2\text{MX}$ ($\text{M} = \text{alkali metal}$); the heat produced is $c. 27,200$ for 2MOH ; the solution of HgBr_2 in HBrAq probably contains the acid H_2HgBr_4 .—3. With mercuric cyanide and potassium cyanide, forms lustrous tablets of $\text{HgBr}_2\cdot\text{HgCy}_2\cdot 2\text{KC}_2\text{H}_3\text{O}$ (Geuthner, *A.* 29, 825). With mercuric cyanide and zinc cyanide, forms transparent prisms of $\text{HgBr}_2\cdot\text{HgCy}_2\cdot\text{ZnCy}_2\cdot 8\text{H}_2\text{O}$ (Varet, *C. R.* 109, 809).—4. Heated with mercuric sulphide, forms $\text{HgBr}_2\cdot 2\text{HgS}$ (Schneider, *P.* 115, 167); this salt is also obtained by boiling HgBr_2Aq with freshly ppd. HgS (H. Rose, *P.* 18, 59) (*v. Mercuric sulphide, Combinations, No. 4, p.* 225).

Mercury, bromide of; v. Mercury, iodobromide of, p. 221.

Mercury, bromosulphide of; v. Mercuric sulphide, Combinations, No. 4, p. 225.

Mercury, chlorides of. Two chlorides are known, HgCl and HgCl_2 . The molecular weight of the latter has been determined from the V.D. of the compound. The numbers obtained for the V.D. of the former agreed with the formula HgCl ; but it was shown that the vapour produced by heating mercurous chloride contained Hg and HgCl_2 , hence the V.D. could not decide between the possible formulæ HgCl and HgCl_2 . More recently it has been found that the V.D. calculated from observations of V.D. of mercurous chloride vaporised into an atmosphere of HgCl_2 agrees with that required by HgCl (*v. infra*).

MERCUROUS CHLORIDE. HgCl (Protochloride of mercury. Calomel). Mol. w. very probably 235.17. Sublimes at 400° – 500° without melting. S.G. 6.993 (Karsten, *S.* 65, 894), to 7.176 (Hassenfratz, *A. Ch.* 28, 3). V.D. 118.6 at 440° (Deville a. Troost, *C. R.* 45, 821); 120.8 (Mitscherlich, *P.* 29, 193). V.D. calculated for $\text{HgCl} = 117.58$. Odling showed that gold-leaf is amalgamated when exposed to calomel vapour at $c. 400^\circ$; hence he concluded that the vapour contained Hg , and that therefore the observed V.D. did not prove the formula HgCl (*J.* 1864, 280). Debray found that only a limited portion of the calomel vaporised at 440° is decomposed with separation of Hg (*C. R.* 83, 330); hence it appears impossible that calomel should have the molecular formula HgCl_2 , else the observed V.D. at $c. 440^\circ$ would be considerably greater than 120 (calc. for $\text{Hg}_2\text{Cl}_2 = 235.16$). In 1881, Fileti showed that when a mixture of mercurous and mercuric chlorides is heated to $c. 400^\circ$ in a Pt tube, containing a tube of silver-gilt traversed by a stream of cold water, not a trace of Hg is deposited on the gilt tube. He then determined the V.D. of a mixture of mercurous and mercuric chlorides, and calculated the V.D. of the mercurous chloride in the mixed vapours; the results were 115.9 and 120.1; hence the molecular formula of calomel is most probably HgCl (*G.* 1481, 341). S.H. at 7° – 99° , .05206 (Regnault, *A. Ch.* [3] 1, 129). Crystallises in tetragonal forms, $\alpha:c = 1:1.7414$. H.F. [HgCl] = 32,600 (Thomsen, *Z. P. C.* 2, 21). For T. C. v. Von Lang, *P.* 135, 29; for heat of vaporisation, v. Marignac, *C. R.* 67, 877.

Occurrence.—As horn-quicksilver; in tetragonal crystals. S.G. 6.482.

Formation.—1. By passing Cl over excess of Hg; action proceeds slowly at ordinary temperatures, rapidly at near B.P. of Hg.—2. By reducing HgCl_2Aq saturated at 50° , by SO_2 (Wöhler, *A.* 90, 124; Bartorius, *A.* 96, 325).—3. By reducing HgCl_2Aq by oxalic acid in sunshine (Eder, *B.* 13, 160).—4. By shaking Hg with FeCl_2Aq .—5. By ppg. a mercurous salt by HClAq .—6. By heating HgCl_2 with Hg.—7. By heating HgSO_4 with Hg and NaCl.—8. By triturating Hg with NaCl, $\text{Fe}_2(\text{SO}_4)_3$, and a little water, till the metal has lost its fluidity, and subliming $(\text{Fe}_2(\text{SO}_4)_3 + 6\text{NaCl} + 2\text{Hg} = 3\text{Na}_2\text{SO}_4 + 2\text{FeCl}_2 + 2\text{HgCl})$.

Preparation.—1. An intimate mixture of 4 pts. HgCl_2 with 3 pts. Hg is made by moistening with alcohol and triturating until the Hg loses its fluidity; the mixture is gently heated for a few hours, again pulverised, and then slowly sublimed in a flask or retort, not more than a quarter filled with the mixture and placed on a thin layer of sand.—2. 4 pts. Hg, 9 pts. dry HgSO_4 , and 3 pts. water are very intimately mixed, a quantity of NaCl equal to the weight of the Hg and HgSO_4 used is added, and the mixture is slowly heated till HgCl_2 sublimes (Planche, *A. Ch.* 66, 168).—3. A well-pulverised mixture of 1 pt. MnO_2 , $1\frac{1}{2}$ pts. NaCl, and $2\frac{1}{2}$ pts. Hg is heated with $2\frac{1}{2}$ pts. conc. H_2SO_4 , until HgCl_2 sublimes. 4. A warm dilute solution of HgNO_3Aq , mixed with a little HNO_3 to prevent formation of basic salts, is ppg. by excess of dilute NaClAq containing a little HCl; the liquid is heated for some time in contact with the pp. which is then thoroughly washed with cold water in the dark (Scheele; cf. Frantwein, *R. P.* 11, 72; 12, 155; Mialhe, *J. Ph.* 22, 586).—5. Cl is passed into HgNO_3Aq ; the pp. of HgCl_2 mixed with HgCl_2 is washed with hot water till HgCl_2 is all dissolved; the HgCl_2 is then crystallised from warm HgNO_3Aq (Siewers, *B.* 21, 647).

Properties.—White, semi-transparent, tetragonal, prisms; if sublimed quickly, forms a fibrous mass of small crystals. When powdered, calomel shows a slight lemon-yellow colour. Highly refractive and dispersive. Tasteless and inodorous. Sublimes without melting. Almost quite insol. water, alcohol, ether, and dilute acids. Sl. sol. cold, more sol. hot, HgNO_3Aq (*v. Debray, C. R.* 70, 995; cf. Drechsel, *J. pr.* [2] 24, 44). Boiled with HClAq , HgCl_2 goes into solution, and Hg is separated; with conc. hot H_2SO_4 , HgCl_2 and HgSO_4 are formed. HgCl_2 is decomposed by solutions of alkalis, alkaline earths, and alkaline carbonates, with ppg. of Hg_2O . For experiments on V.D. of calomel, *v. supra*.

Reactions.—1. Exposed to sunlight, HgCl_2 darkens with separation of Hg (for action of heat on HgCl *v. supra*).—2. Partly decomposed by aqueous vapour or boiling water, with production of HgCl and Hg.—3. Decomposed by many metals when heated with them in presence or absence of water, giving metallic chlorides and Hg.—4. Triturated with iodine and water, HgCl_2 and HgI_2 are produced (Planche a. Soubeiran, *J. Ph.* 12, 661).—5. Heated with a little sulphur, HgS and HgCl_2 are formed; with excess of S, the products are HgS and S_2Cl_2 .—6. Heated in phosphorus vapour, HgCl_2 yields PCl_3 and $\text{Hg}_3\text{P}_2\text{S}_4$ (Lavy).—7. By heating an intimate

mixture of 3 pts. HgCl_2 with 1 pt. arsenic, a sublimate is obtained consisting in part of yellow tetrahedral crystals; according to Capitaine (*J. pr.* 18, 422) these crystals are *mercuri-arsenic chloride* AsHgCl . The compound is decomposed by hot water to As-Hg amalgam, As_2O_3 , and HCl; it is partly decomposed by heat, giving Hg, As, and AsCl_3 .—8. Reduced by sulphurous acid, also by hot stannous chloride solution, with separation of Hg.—9. Cold sulphuric acid has no action on HgCl_2 ; the hot conc. acid forms HgCl_2 , HgSO_4 , and SO_2 .—10. Dissolved by hot nitric acid with evolution of NO; the solution contains $\text{Hg}(\text{NO}_3)_2$ and HgCl_2 .—11. Boiling hydrochloric acid forms HgCl_2 and Hg; boiled in an open vessel with water and a little HCl, no Hg is separated, but HgCl_2 goes into solution.—12. Decomposed by hydrocyanic acid solution, forming HgCy_2 , Hg, and HCl.—13. With solution of alkali chlorides forms HgCl_2 , which combines with the excess of alkali chloride to form double salts, some of which are soluble and some insoluble.—14. Digested with solutions of alkali iodides, or iodide of magnesium, or iron, HgI_2 is separated, and metallic chloride goes into solution.—15. Solutions of alkalis form Hg_2O and alkali chloride; heated with solid alkalis, Hg, O, and alkali chloride are produced.—16. Ammonia produces black $\text{NH}_2\text{Hg}_2\text{Cl}$ (*v. MERCURAMMONIUM COMPOUNDS*).—17. Heated with carbonates of calcium, barium, or magnesium, Hg, Hg_2O , and HgO are separated, and CO_2 is evolved (Buchner, *R. P.* 3, 81; 4, 289; Vogel, *R. P.* [3] 1, 34).—18. With alkali sulphites in solution, Hg separates, and a double sulphite of Hg and alkali metal goes into solution. 19. Rubbed with antimony tri- or penta-sulphide, HgS and SbCl_3 are formed.

Testing calomel for impurities.— HgCl_2 sometimes contains HgCl , HgNO_3 , or $\text{Hg}(\text{NO}_3)_2$, or Hg. HgCl_2 is detected by shaking with water, filtering, and adding SnCl_2Aq , when a white-grey pp. is produced. Bñanewyn (*Bl.* [2] 4, 201) says that $\frac{1}{500000}$ pt. of HgCl in HgCl_2 may be detected by immersing a clean knife-blade in the calomel moistened with alcohol or ether; if HgCl_2 is present a black spot is formed on the blade. HgNO_3 , or $\text{Hg}(\text{NO}_3)_2$, is detected by heating, when NO_2 is evolved. Hg may be detected by examination under the microscope. HgCl_2 may be adulterated with powdered heavy spar, &c.; this remains unchanged on sublimation. Adulteration with gum or other organic material is detected by the smell produced on heating.

Combinations.—1. With sulphur chloride, to form $2\text{HgCl}_2\text{SCL}_2$, produced by long-continued warming HgCl_2 with S_2Cl_2 ; also by heating an intimate mixture of 31 pts. HgCl_2 and 2 pts. S in a dish covered with a funnel, on to which the double compound sublimes; also by heating As_2S_3 with HgCl_2 .

$(7\text{HgCl}_2 + \text{As}_2\text{S}_3 = 2\text{AsCl}_3 + 8\text{HgS} + 2\text{Hg}_2\text{SCL}_2)$. Forms rectangular needles, which melt to a brown liquid, and volatilise without decomposition; decomposed by water (Capitaine, *J. pr.* 18, 422).—2. With stannous chloride to form $2\text{HgCl}_2\text{SnCl}_2$. Produced by heating an amalgam of 8 pts. Sn with 1 pt. Hg mixed with 24 pts. HgCl_2 , and subliming. Forms white demeritric crystals; partially decomposed by heat:

wholly decomposed by water, with formation of SnCl_2 , which reduces the HgCl (Capitaine, *J. pr.* 18, 422).—S. H. Rose (*P.* 44, 825) states that HgCl combines with sulphur dioxide.

MERCURIC CHLORIDE. HgCl_2 . (*Perchloride of mercury. Corrosive sublimate.*) Mol. w. 270.54. [288°] (Carnelley, *C. J.* 33, 276). (803°) (Carnelley & Williams, *C. J.* 33, 282). S.G. 6.223 (Playfair & Joule, *C. S. Mem.* 2, 401); 5.448 (Schröder, *P.* 107, 118). V_D 136.3 (Mitscherlich, *P.* 29, 193). S.H. 12° – 45° .064 (Kopp, *Tr.* 155, 71); 13° – 98° .06889 (Regnault, *A. Ch.* [3] 1, 120). S. 5.73 at 0° , 6.57 at 10° , 7.39 at 20° , 8.43 at 30° , 9.62 at 40° , 11.34 at 50° , 13.86 at 60° , 17.29 at 70° , 24.32 at 80° , 37.05 at 90° , 53.96 at 100° (Poggiale, *A. Ch.* [3] 8, 463). S. cold alcohol 43.5, boiling alcohol 86.2; S. ether 33; S. glycerin 7 (Fairley, *M. S.* [3] 9, 685). Crystallises in two forms belonging to the trimetric system: (i) crystals from alcoholic solution, $a:b:c = .754:1:1.0686$; (ii) crystals by sublimation, $a:b:c = .9347:1:1.3396$ (v. Mitscherlich, *P.* 28, 118; Von Lang, *W. A. B.* 45, 119). H.F. [Hg, Cl] = 54,490 (Thomsen, *Z. P. C.* 2, 21).

Occurrence.—In a volcanic district on Ternate, one of the Molucca islands (Frenzel, *Min. Mittheil.* 1877. 305).

Formation.—1. By heating Hg in excess of Cl. 2. By dissolving HgO in hot HClAq , and evaporating.—3. By dissolving Hg in hot HClAq containing some HNO_3 , evaporating, and recrystallising from hot water.—4. By adding excess of Cl to a slightly acid solution of $\text{Hg}(\text{NO}_3)_2$ (Siewers, *B.* 21, 647).

Preparation.—1. An intimate mixture of equal parts NaCl and HgSO_4 (obtained by boiling 4 pts. Hg with 5 pts. conc. H_2SO_4 till a dry mass is formed), to which a little MnO_2 has been added (to prevent formation of HgCl from Hg_2SO_4 , which may be present), is slowly heated in a long-necked flask or retort; HgCl_2 sublimes on the cooler parts of the apparatus. The operation must be conducted in a good draught-cupboard because of the very poisonous nature of HgCl_2 .—2. Boiling conc. HgNO_3Aq is mixed with conc. HClAq as long as a pp. forms; the pp. of HgCl is boiled with as much HClAq as was used in its formation ($\text{HgNO}_3\text{Aq} + 2\text{HCl} = \text{HgCl}_2\text{Aq} + \text{H}_2\text{O} + \text{NO}$); crystals of HgCl_2 separate on cooling; they may be recrystallised from hot water.

Properties.—Translucent crystals, forming a white powder when crushed. HgCl_2 has a disagreeable metallic taste; it is extremely poisonous. Melts at 288° (v. *supra*) to a colourless liquid; according to Haas, HgCl_2 does not melt when heated if the pressure is less than 120 mm. (*B.* 13, 2203). Easily sol. water; sol. alcohol, ether, and glycerin (v. *supra*). Schröder (*J. R.* 1886. 18) gives the following table, showing the S.G. of aqueous and alcoholic solutions of HgCl_2 , and the percentage of HgCl_2 in these solutions:—

P. HgCl_2 .	Aqueous solutions of HgCl_2 .

HgCl_2Aq reacts slightly acid to litmus. On boiling HgCl_2Aq some HgCl passes off with the steam. HgCl_2Aq is decomposed by light with evolution of O and formation of HCl and Hg oxychloride (cf. V. Meyer, *B.* 20, 2970).

Reactions.—1. Many metals decompose HgCl_2 , when heated with it, forming HgCl or Hg; such metals are Sb, As, Bi, Cu, Fe, Pb, Ni, Sn. Many metals also reduce HgCl_2 in aqueous solution, generally ppg. HgCl and Hg; Cd, Fe, and Zn pp. Hg only.—2. Reducing agents, e.g. SnCl_2Aq , SO_2Aq , formic acid, oxalic acid, produce HgCl (cf. Eder, *B.* 13, 166; also Wurtz's *Dictionnaire*, *Suppl.* p. 1066).—3. With many carbon compounds, HgCl_2 forms HgCl and HCl (the H being withdrawn from the C compound).—4. HgCl_2 is not decomposed by sulphuric or nitric acid; it dissolves fairly easily in HNO_3Aq .—5. Dissolves in hot conc. hydrochloric acid; on cooling, a white crystalline mass is obtained which has the composition $2\text{HgCl}_2 \cdot \text{HCl}$ according to Boullay (*A. Ch.* 34, 243; cf. *Combinations*, No. 1).—6. According to Fairley (*B. A.* 1875. 42), hypochlorites reduce HgCl_2 to HgCl .—7. Albumen is rapidly coagulated and ppg. by HgCl_2Aq ; white of egg serves as an antidote to poisoning by corrosive sublimate.—8. Boiled with mercuric oxide, oxychlorides are obtained (v. MERCURY, OXYCHLORIDES or, p. 223).—9. Alkalis produce HgO and alkali chloride.—10. Normal potassium or sodium carbonate ppts. HgO ; K(or Na) HCO_3 is also formed, and this reacts with the rest of the HgCl_2 to pp. oxychlorides.—11. Potassium (or sodium) hydrogen carbonate produces various oxychlorides (q.v. p. 223).—12. Phosphorus trihydride produces a black pp. when passed into HgCl_2 dissolved in water or alcohol; on continuing the passage of PH_3 , the pp. becomes yellow, and then has the composition $\text{P}_2\text{Hg}_3 \cdot 3\text{HgCl}_2 \cdot 3\text{H}_2\text{O} = 2(\text{PHgCl} \cdot \text{HgCl}_2) \cdot 3\text{H}_2\text{O}$; the solution contains HCl. This compound is known as *dimercuri phosphonium-mercuric chloride*; it must be washed quickly with cold water, and dried over H_2SO_4 in *vacuo*; it is decomposed by hot water, giving Hg, HCl, and H_3PO_4 ; heat produces HCl, Hg, and H_3PO_4 (H. Rose, *P.* 40, 75).—13. Arsenic trihydride produces a brown-yellow pp. in HgCl_2Aq . This pp. has the composition $\text{AsHgCl} \cdot \text{HgCl}_2$; it is known as *dimercuriarsonium-mercuric chloride*. The pp. is washed with cold water and quickly dried over H_2SO_4 in *vacuo*; it is decomposed by water to Hg, As_2O_3 , and HCl (H. Rose, *P.* 51, 423).

Combinations.—1. With hydrochloric acid; according to Boullay (*A. Ch.* 34, 243) the compound $2\text{HgCl}_2 \cdot \text{HCl}$ is obtained by dissolving HgCl_2 in hot conc. HClAq , and cooling; this

compound forms a crystalline lustrous mass which melts by the heat of the hand (v. also Ditte, *C. R.* 92, 358). Neumann (*M.* 10, 236) obtained *chloromercuric acid* HHgCl_2 by gently warming excess of HgCl_2 with HClAq , filtering through asbestos, and cooling to between 0° and -4° . This acid is very readily decomposed by heat or moisture. Solutions of HgCl_2 in HClAq react with alkalis to form $\text{HgCl}_2 \cdot 2\text{MX}$ (M = alkali metal); the heat produced in the reaction is c. 27,200 for 2MOH; the solution of HgCl_2 in HClAq probably contains the acid H_2HgCl_4 . Dry HCl passed over well-cooled HgCl_2 has no action (N., l.c.).—2. With many chlorides and with some other salts. The chief compounds with other chlorides are the following (v. Von Bonsdorff, *P.* 17, 115):—

(i) With phosphorus pentachloride: $8\text{HgCl}_2 \cdot 2\text{PCl}_5$. Pearl-white needles; sublimes unchanged; decomposed by water; formed by heating the constituents together (Baudrimont, *A. Ch.* [4] 2, 45).

(ii) With alkali chlorides. (a) With potassium chloride: $2\text{KCl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$; $\text{KCl} \cdot \text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. The first salt is formed by saturating KClAq with HgCl_2 at 30° , adding as much KCl as originally used, and evaporating. The second salt is produced by evaporating a solution of equal equivalents of KCl and HgCl_2 (Rammelsberg, *P.* 90, 34). The third salt results by saturating KClAq at 60° with HgCl_2 and allowing to cool. The compound $6\text{KCl} \cdot 3\text{HgCl}_2 \cdot \text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ was obtained by Von Bonsdorff (*P.* 83, 81) by adding CuCl_2Aq to a dilute solution of $\text{KCl} \cdot \text{HgCl}_2$. (b) With sodium chloride: $2(\text{NaCl} \cdot \text{HgCl}_2) \cdot 3\text{H}_2\text{O}$; $2\text{NaCl} \cdot \text{HgCl}_2$. The first salt is obtained by adding NaCl to NaClAq saturated with HgCl_2 . The second salt is produced by adding alcohol to saturated NaClAq shaken with powdered HgCl_2 . (c) With rubidium chloride: $2\text{RbCl} \cdot \text{HgCl}_2$; $\text{RbCl} \cdot 2\text{HgCl}_2$; $\text{RbCl} \cdot \text{HgCl}_2$. Obtained, respectively, by evaporating a neutral solution of RbCl and HgCl_2 , by evaporating a solution of equal parts of the constituent salts, and by heating the second salt to 50 (Godeffroy, *Ar. Ph.* [3] 12, 47). (d) With ammonium chloride: $2\text{NH}_4\text{Cl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$ (*sal alembrothi*) is obtained by evaporating a solution of 1 pt. NH_4Cl and 2 pts. HgCl_2 ; loses H_2O in dry air; isomorphous with the corresponding K salt. The other salts obtained are $\text{NH}_4\text{Cl} \cdot \text{HgCl}_2$, $2\text{NH}_4\text{Cl} \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$ (Kane); $2\text{NH}_4\text{Cl} \cdot 9\text{HgCl}_2$, and $2\text{NH}_4\text{Cl} \cdot 8\text{HgCl}_2 \cdot 4\text{H}_2\text{O}$ (Holmes, *C. N.* 5, 861).

(iii) With alkaline earth chlorides. (a) With calcium chloride: $\text{CaCl}_2 \cdot 5\text{HgCl}_2 \cdot 8\text{H}_2\text{O}$; by saturating warm CaCl_2Aq with HgCl_2 , and cooling; by evaporating the mother-liquor the salt $\text{CaCl}_2 \cdot 2\text{HgCl}_2 \cdot 6\text{H}_2\text{O}$ is obtained. (b) With strontium chloride: $\text{SrCl}_2 \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. (c) With barium chloride: $\text{BaCl}_2 \cdot 2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. (d) With magnesium chloride: $\text{MgCl}_2 \cdot 3\text{HgCl}_2 \cdot 5\text{H}_2\text{O}$ and $\text{MgCl}_2 \cdot \text{HgCl}_2 \cdot 6\text{H}_2\text{O}$.

(iv) With chloride of zinc: $\text{ZnCl}_2 \cdot \text{HgCl}_2 \cdot 4\text{H}_2\text{O}$; by evaporating a mixed solution of the constituents. Analogous salts with CuCl_2 , CoCl_2 , NiCl_2 , and FeCl_2 have been obtained.

The chief compounds with oxyacids are the following:—

(i) With ammonium sulphide:

$3\text{HgCl}_2 \cdot 2(\text{NH}_4)_2\text{SO}_3$. By adding hot saturated HgCl_2Aq to cold $(\text{NH}_4)_2\text{SO}_3\text{Aq}$ (P. de Saint-Gilles, *A.* 84, 266, 269).

(ii) With potassium chromate, and dichromate: (a) $\text{HgCl}_2 \cdot \text{K}_2\text{Cr}_2\text{O}_7$; by cooling a warm solution of equivalents of the two salts (Millon, *A. Ch.* [3] 18, 388; Darby, *C. S. Mem.* 1, 24). (b) $2\text{HgCl}_2 \cdot \text{K}_2\text{CrO}_4$; by mixing solutions of the constituent salts in the ratio $2\text{HgCl}_2 \cdot \text{K}_2\text{CrO}_4$, adding HClAq sufficient to dissolve ppd. HgCrO_4 , and evaporating (Darby, l.c.).

(iii) With ammonium dichromate: (a) $\text{HgCl}_2 \cdot (\text{NH}_4)_2\text{Cr}_2\text{O}_7 \cdot \text{H}_2\text{O}$; by evaporating a solution of the constituents (Abel a. Richmond, *C. J.* 3, 202; cf. Darby, *C. S. Mem.* 1, 24; Zepharovich, *W. A. B.* 39, 17). (b) $\text{HgCl}_2 \cdot 3(\text{NH}_4)_2\text{CrO}_4$; by evaporating the mother-liquor from the first salt (A. a. R., l.c.; cf. Clarke a. Stern, *Am. Ch.* 3, 351).

(iv) With copper acetate: $2\text{HgCl}_2 \cdot \text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{CuO}$; deposited from a mixture of cold saturated solutions of HgCl_2 and $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2$ (Hutteroth a. Wöhler, *A.* 53, 142).

(v) With chlorochrometrammonium chloride: $6\text{HgCl}_2 \cdot \text{Cl}_2\text{Cr} \cdot 8\text{NH}_4\text{Cl}$; by spontaneous evaporation of a mixed solution of the two salts (Clève, *J.* 1862, 150).

3. Compounds of HgCl_2 with PH_3Cl and AsH_3Cl are known. (a) *Dimercuriphosphonium-mercuric chloride* $2(\text{PH}_3\text{Cl} \cdot \text{HgCl}_2) \cdot 3\text{H}_2\text{O}$; a yellow solid formed by passing PH_3 into HgCl_2 dissolved in water or alcohol (v. *Reactions*, No. 12). (b) *Dimercuriarsonium-mercuric chloride* $\text{AsH}_3\text{Cl} \cdot \text{HgCl}_2$; a brown-yellow pp. by passing AsH_3 into HgCl_2Aq (v. *Reactions*, No. 13).—4. A compound of HgCl_2 with *mercuric sulphocyanide*— $\text{HgCl}_2 \cdot \text{Hg}(\text{SCN})_2$ —is obtained by the reaction of SOCl_2 with $\text{Hg}(\text{SCN})_2$ (McMurtroy, *C. J.* 55, 50).

Mercury, chlorocyanide of; v. *Mercury, cyanochloride of*, infra.

Mercury, chlorosulphides of; v. *Mercuric sulphide, Combinations*, No. 4, p. 225.

Mercury, chloro-iodides of; v. *Mercury, iodochlorides of*, p. 221.

Mercury, chromates of; v. vol. ii. p. 155.

Mercury, cyanides of; v. vol. ii. p. 342.

Mercury, cyanochloride of. Hg_2CyCl . Quadratic prisms; stable in air; produced by evaporating an aqueous solution of equivalent weights of HgCl_2 and HgCy_2 (Liebig, *S.* 49, 253; Poggiale, *C. R.* 23, 762; cf. Woeren, *J. pr.* 64, 63).

Mercury, cyanoselenides and cyanosulphides of; v. *Mercury, selenocyanides and sulphocyanides of*, under *CYANIDES*, vol. ii. pp. 348 and 350.

Mercury, ferrocyanides of; v. vol. ii. p. 385.

Mercury, fluorides of. Two are known, HgF and HgF_2 ; the V.D. of neither has been determined. These fluorides are remarkably unstable both as regards the action of water and of heat.

Mercurous fluorides. HgF or Hg_2F_2 . Prepared by adding freshly ppd. Hg_2CO_3 to HFAq so long as the salt is dissolved, and evaporating; also by adding recently prepared HgCl_2 to a solution of Ag_2CO_3 in HFAq , filtering from AgCl , and evaporating on a steam-bath (Finkener, *A.* 110, 142). Berzelius obtained HgF , mixed with HgCl_2 , by subliming a mixture of HgCl_2 with NaF . HgF is a light yellow, crystalline, powder. It is partly

dissolved, and partly decomposed to HF and HgO, by water. Exposed to light when moist it is blackened. HgF may be heated to c. 200° without change; above this temperature Hg sublimes and the glass vessel is corroded. HgF is decomposed by alkalis with separation of HgO; the action of NH₄Aq is more complex. HgF absorbs NH₃ gas forming N₂H₄HgF₂ (v. *Mercurammonium compounds*, p. 206). Combines with SiF₄ to form *Mercurous silicofluoride* Hg₂SiF₆·2H₂O (v. *Mercury, silicofluorides of*, p. 224).

MERCURIC FLUORIDE. HgF₂. According to Fremy (*A. Ch.* [3] 47, 5), crystals of this compound are obtained by dissolving HgO in excess of HF₄Aq, and evaporating the solution slowly over lime. Finkener (*P.* 110, 628) obtained an *oxyfluoride*, HgF₂·HgO·H₂O, by this method; by adding conc. HF₄Aq (50 p.c.) to this oxyfluoride, it was suddenly changed to a white crystalline mass of HgF₂·2H₂O (Finkener, *l.c.*). The hydrated fluoride is decomposed at 30°, giving H₂O, HF, and HgO.HgF₂·H₂O (F.). HgF₂ is decomposed by water with separation of HgO. Addition of slight excess of NH₄Aq to HgF₂ in HF₄Aq ppts. NH₄Hg₂OF₂·HF (Finkener, *P.* 110, 632). *Mercuric silicofluoride* HgSiF₆·6H₂O probably exists (v. *Mercury, silicofluorides of*, p. 224). Berzelius obtained a compound of HgF₂ with NH₄F by treating HgF₂ with NH₄Aq. HgF₂ combines with H₂S (v. *Mercuric sulphide, Combinations*, No. 6, p. 225).

Mercury, fuosulphide of; v. Mercuric sulphide, Combinations, No. 6, p. 225.

Mercury, fulminate of; v. vol. ii. p. 317.

Mercury, haloid compounds of. Two series of these compounds exist, HgX and HgX₂. The molecular weights of HgCl₂, HgBr₂, and HgI₂ are known; the molecular weights of HgCl, HgBr, and HgI are probably as represented by these formulæ. The compound Hg₂LIgI₂ also exists, and a periodide of Hg has been isolated. The mercurous compounds HgX are insoluble in water, except HgF, which is partly dissolved, and partly decomposed, by water; the mercuric compounds HgX₂ are soluble in water, with the exception of HgF₂, which is decomposed by water. The Hg haloid compounds combine with many other haloid compounds, and also with oxysalts, to form numerous double salts. The double salts of the type HgX₂·M'X and HgX₂·2M'X are best regarded as salts of the mercur-halogen acids HHgX, and H₂HgX, respectively; the acids HHgX₂ have been isolated, and probably also the acids H₂HgX₂. The heats of formation of HgX and HgX₂ decrease as the atomic weight of X increases. Thomsen gives the following data (*Z. P. C.* 2, 21):—

X	[Hg.X]	X	[Hg.X]
Cl	32,605	Cl	54,490
Br	25,475	Br	41,880
I	15,550	I	25,640.

An iodochloride Hg₂Cl₂ and an iodobromide HgIBr, have been isolated.

Mercury, hydrated oxide of. According to Carnelley a. Walker (*C. J.* 53, 80), the hydrate HgO.H₂O is obtained by ppg. HgCl₂Aq by NaOH₄Aq, and drying in air; it is stable to about 100°, and is completely dehydrated at c. 175°. According to Schaffner (*A.* 51, 181) the yellow pp. formed by adding KOHAq to solution of a

mercuric salt is HgO.8H₂O (v. *Mercuric oxide*, p. 222). But according to Millon (*B. J.* 27, 112), Marchand (*J. pr.* 37, 277), Rammelsberg (*J. pr.* [2] 38, 559), and Wallace (*Chem. Gazette*, 1858, 345), the pp. obtained from Hg salts by KOHAq is HgO.

Mercury, iodides of. Besides the iodides HgI and HgI₂, corresponding with the chlorides, bromides, and fluorides, of Hg, there is said to exist a definite mercurio-mercuric iodide, HgI.HgI₂, and a hexa-iodide HgI₆. Hg and I combine directly with production of heat.

MERCUROUS IODIDE. HgI or HgI₂. Mol. w. not known with certainty. Melts at c. 290° (with partial decomposition according to Stroman, *B.* 20, 2818). Boils at c. 310° with partial decomposition (Yvon, *C. R.* 76, 1607). S.G. 7.75 (Boullay, *A. Ch.* [2] 43, 266). S.H. 17°-99° 0.3949 (Regnault, *A. Ch.* [3] 1, 129). Crystallises in tetragonal forms, $\alpha:c = 1:1.6726$ (Des Cloiseaux, *C. R.* 84, 1418). H.F. [Hg.I] = 15,550 (Thomsen, *Z. P. C.* 2, 21).

Formation.—1. By rubbing together Hg and I, in the ratio Hg:I, moistened with a few drops of alcohol, and removing the small quantity of HgI, which is always formed by treatment with alcohol, in which HgI₂ is soluble but HgI is insoluble.—2. By rubbing together HgI₂ and Hg in the ratio HgI₂:Hg, and dissolving out unchanged HgI₂ by alcohol.—3. By heating 10 parts I with 15½ parts Hg in a retort, on a sand-bath, to not above 250°; HgI sublimes in red crystals, becoming yellow when cold (Yvon, *C. R.* 76, 1607). 4. By adding KIAq to solution of a mercuric salt, preferably the acetate (v. Lefort, *Ph.* [3] 3, 823).

Preparation.—A conc. solution of HgNO₃, containing a little HNO₃, and free from basic nitrate, is heated to boiling with excess of I; when the I is partially dissolved the liquid is carefully decanted into a warm basin; on cooling, very lustrous, transparent, yellow tablets of HgI separate. The crystals are brought on to a filter (best in the dark), washed with cold water containing a little HNO₃, and then with pure cold water, and dried in the dark at ordinary summer-temperature by placing them on filter paper which is frequently changed (Stroman, *B.* 20, 2818). HgI is obtained as a flocculent pp. by rapidly adding a fairly conc. solution of I in alcohol to cold conc. HgNO₃Aq (S., *l.c.*).

Properties and Reactions.—HgI crystallises in yellow tetragonal tablets, isomorphous with HgCl. HgI is sometimes described as a green powder. Stroman (*l.c.*) says that green preparations are impure. When heated, the yellow crystals become dark yellow, then orange, and finally garnet-red. Yvon (*C. R.* 76, 1607) says that the change of colour begins at 70°, and assigns a definite temperature for each change of colour. Stroman (*B.* 20, 2818) could not connect the different colours with definite intervals of temperature; he says that the salt prepared by him was pure yellow at 100°. Sublimation begins at c. 190° according to Yvon, at c. 110°-120° according to Stroman. HgI when moist is rapidly blackened by light. HgI is very slightly soluble in water; insoluble in alcohol. It is easily decomposed to Hg and HgI₂, e.g. by HIAq, KIAq, and similar iodides. Heated rapidly HgI gives a sublimate of Hg and HgI.HgI₂. HgI

is used in medicine. For medicinal purposes it must be quite free from HgI_2 , which is a violent poison.

MERCURIO-MERCURIOD IODIDE. $HgI.HgI_2$. A compound of Hg and I of this composition was obtained by Boullay (*A. Ch.* [2] 34, 845) by adding KIAq containing I, in the ratio KI:I, to $HgNO_3.Aq$. The same compound is said to be obtained by adding KIAq to $HgNO_3.Aq$ and digesting the pp. for some time in the liquid; also by rubbing together HgI_2 and I in the ratio $8HgI_2:Hg$. Mercurio-mercuriod iodide is described as a yellow powder, insol. water and alcohol; unchanged in the dark, but becoming dark when exposed to light. When heated, it turns red, then melts, and may be sublimed unchanged, yielding crystals which are red when hot but become yellow on cooling. HIAq, and various iodides in solution, dissolve HgI_2 , leaving HgI, and then decompose the HgI with separation of Hg.

MERCURIOD IODIDE. HgI_2 . Mol. w. 452.86. [238°] (Carnelley a. Williams, *O. J.* 33, 283). (339°-359°) (C. a. W., *L.c.*). S.G. red variety 6.2941 to 6.3004 at 0°, 6.276 at 126°; yellow variety 6.225 at 126° (Rodwell a. Elder, *Pr.* 28, 284); 6.179 at 200° solid; 5.286 at 200° molten (R. a. E., *L.c.*). V.D. 225.7 to 234.4 (Mitscherlich, *P.* 29, 193). S.H. 18°-99°-0.4197 (Regnault, *A. Ch.* [3] 1, 129). Crystallises in tetragonal forms (red), $ax = 1.1:9.955$; also in rhombic forms (yellow), $p:p = 114^\circ 30'$. H.F. [HgI_2] = 25,640 (Thomsen, *Z. P. C.* 2, 21). Change of yellow to red crystals is accompanied by production of heat; 8000 gram-units (Berthelot, *Bl.* [2] 39, 17; cf. Weber, *P.* 100, 127). S. -004 at 17.5°, -005 at 22°; S. -286 60 p.c. alcohol at 18°, 1.186 absolute alcohol at 18° (Bourgoin, *Bl.* [2] 42, 620).

Formation.—1. By the action of I on Hg; Dublane (*Ph. C.* 1849, 656) says that pure HgI_2 is obtained by pouring 1,000 pts. alcohol (93 p.c.) on to 100 pts. Hg, and adding 124 pts. I in portions of 10 pts. at a time; after each addition of I, the whole is agitated until the alcohol becomes colourless; the addition of the last portion of I should leave the alcohol coloured; the HgI_2 is washed with alcohol.—2. By adding KIAq or $FeI_2.Aq$ to $HgCl_2.Aq$.

Preparation.—1. 8 pts. $HgCl_2$ and 10 pts. KI are dissolved, separately, in water; the solutions are mixed, and the pp. is thoroughly washed with cold water. Any excess of KI dissolves some HgI_2 , and any excess of $HgCl_2$ produces a yellowish pp. containing more or less $HgCl_2$. Williams (*Ph.* [3] 3, 1015) dissolves 8 pts. $HgCl_2$ in 4 pts. NH_4Cl in water, and then adds 10 pts. KI in water.—2. 10 pts. I are suspended in water, and Fe filings are added until all the I is changed to FeI_2 ; the solution is at once added to a solution of 10½ pts. $HgCl_2$ in water, the pp. of HgI_2 is rapidly separated from the liquid (to prevent formation of Fe oxychlorides) and washed with cold water. B. crystallising from hot KIAq, or, better, from hot conc. $HCl.Aq$ (Köhler, *B.* 12, 608), HgI_2 is obtained in very lustrous, red tetragonal prisms, with a greenish reflection.

Properties.— HgI_2 obtained by ppn. is a pure scarlet-coloured, crystalline, heavy powder. It is sl. sol. water; S. -66 (Wurts). Sol. hot alcohol; somewhat sol. glycerin (in 840 pts., Fairley,

M. S. [3] 9, 685); also in ether, and some oils. Sol. KIAq, also in conc. hot $HCl.Aq$; from these solutions HgI_2 separates in well-formed crystals. HgI_2 is dimorphous. Red (tetragonal, HgI_2 is changed to the yellow (rhombic) modification by heat; the change occurs at 126° (Rodwell a. Elder, *Pr.* 28, 284); it is accompanied by a sudden, and then by a regular, expansion. S.G., red at 126° = 6.276, yellow at 126° = 6.225 (R. a. E.). HgI_2 melts at 238° (Carnelley a. Williams, *O. J.* 33, 283), at 253°-254° according to Köhler (*B.* 12, 608), to a blood-red liquid; melting is attended with considerable expansion. At c. 339°-359° the liquid boils, and sublimes to yellow rhombic plates. The yellow variety passes into the red at the ordinary temperature; this change is hastened by rubbing or scratching the red crystals; heat is produced in the process, 3,000 gram-units according to Berthelot (cf. Weber, *P.* 100, 127). The HgI_2 obtained by adding cold KIAq to cold $HgCl_2.Aq$ appears at first yellow, but it quickly changes to red; the change of crystalline form in this case may be observed under the microscope. Solutions of HgI_2 in alcohol, ether, or KIAq are colourless; if the HgI_2 is allowed to form slowly from these solutions, the crystals are red; but if the ppn. is made rapid, e.g. by pouring an alcoholic solution into water, the crystals appear yellow for a moment, but they quickly change to red (cf. Schiff, *A.* 111, 371; Selmi, *J.* 1855, 417).

Reactions.—1. HgI_2 dissolves in *hydriodic acid* solution with production of heat (v. Berthelot, *Bl.* 38, 369). This solution has about the same heat of neutralisation as HIAq (Thomsen); with alkalis it forms salts $HgI_2.2MI$; the solution very probably contains the acid H_2HgI_4 (cf. *Combinations*, No. 2). An *iodomercuric acid*, $HHgI_2$, has been obtained by slightly warming excess of HgI_2 with HIAq, filtering through asbestos, and cooling to between 0° and -4° (Neumann, *M.* 10, 236); this acid is very readily decomposed by moisture and by heat. According to Boullay (*A. Ch.* [2] 34, 345) a solution of HgI_2 in hot HIAq deposits I on cooling, and then crystals of $2HgI_2.3HI$.—2. Most *heavy metals*, e.g. Zn, Sn, when triturated with HgI_2 remove I and leave Hg; *potassium* acts in the same way.—3. $HgI_2.Aq$ is decomposed by *alkalis*, with separation of HgO and formation in solution of a double salt $xHgI_2.yMI$. *Baryta* and *strontia* react similarly to alkalis.—4. *Lime*, *sodium carbonate*, and *potassium carbonate* do not decompose $HgI_2.Aq$; but a solution of HgI_2 in alcohol is decomposed by these reagents.—5. HgI_2 dissolves in hot *calcium hypochlorite* solution; on cooling Ca periodate is deposited and $HgCl_2$ remains in solution (Rammelsberg). 6. When HgI_2 is boiled with *nitric acid*, S.G. 1.5-1.4, $Hg(IO_3)_2$ is formed; with acid S.G. 1.2, white leaflets of $HgI_2.Hg(NO_3)_2$ separate; with acid S.G. 1.2, crystals of unchanged HgI_2 are obtained, together with some of the compound $HgI_2.Hg(NO_3)_2$ (Kraut, *B.* 18, 3461).—7. *Chlorine*, passed into water containing HgI_2 in suspension, produces a yellow solution containing $HgCl_2$ and ICl (Filhol).

Combinations.—1. With *hydriodic acid* (v. *Reactions*, No. 1).—2. With various *metalliferous iodides* to form double salts, regarded by Von Bonsdorff as *iodomercurates* (*P.* 17, 265).

These salts have been examined chiefly by Boullay (*A. Ch.* [2] 84, 845). They are generally obtained by dissolving HgI_2 in a solution of the other iodide and evaporating. The following are the most important:—

(i) With alkali iodides. (a) With potassium iodide: $2HgI_2 \cdot 2KI \cdot 3H_2O$; $HgI_2 \cdot 2KI$. The former is produced by saturating boiling $KIAq$ with HgI_2 , filtering, separating from HgI_2 , which crystallises out, and evaporating. Sol. alcohol and ether. Decomposed by water, with formation of HgI_2 , and $HgI_2 \cdot 2KI$ which separates on evaporation. These soluble salts may be prepared by boiling $KIAq$ with HgO ; the solution contains the double salts and also KOH (*cf. Jehn, Ar. Ph.* [3] 1, 97). (b) With sodium iodide: $NaIAq$ reacts with HgI_2 similarly to $KIAq$; the compositions of the double salts of NaI with HgI_2 have not been satisfactorily determined. (c) With ammonium iodide: $2(NH_4I \cdot HgI_2) \cdot 3H_2O$; obtained, as yellow needles, by dissolving HgI_2 in hot NH_4IAq , separating from HgI_2 , which forms on cooling, and evaporating.

(ii) With other metallic iodides. BaI_2 , SrI_2 , CaI_2 , and MgI_2 solutions react with HgI_2 similarly to $KIAq$; the double salts are probably $MI_2 \cdot HgI_2$. HgI_2 appears to form double compounds with CdI_2 and FeI_2 . The compound $2HgI_2 \cdot CuI_2$ was obtained by Hess (*D. P. J.* 218, 183).—3. HgI_2 combines with mercuric chloride, also with mercuric bromide (*v. Mercury, iodochlorides and iodobromides of, infra*).—4. Combines with mercuric sulphide (*v. Mercury sulphide, Combinations*, No. 5, p. 225).

MERCURY, HEXA-IODIDE OF. HgI_6 . This periodide is said by Jørgensen (*J. pr.* [2] 2, 357) to be obtained by adding cold $HgCl_2Aq$, followed by addition of water, to an alcoholic solution of KI , heated to 50° . If the solutions are mixed hot, large rhombic crystals of HgI_6 are formed, but they are always mixed with HgI_2 . HgI_6 is decomposed quickly by alcohol, slowly by water, with formation of red HgI_2 . HgI_6 possesses most of the optical properties of tourmalin.

Mercury, iodobromide of. $HgIBr$. Sulphur-yellow, translucent, rhombic prisms, $a:b:c = 6443:1:9194$ (Groth, *B. 2*, 574). Melts at $c. 229^\circ$, and boils at $c. 360^\circ$; crystallisable from ether; may be sublimed unchanged. Produced by crystallising a mixture of HgI_2 and $HgBr$, from ether or acetone; also by the reaction of an alkyl iodide, *e.g.* EtI , on $HgBr$, dissolved in acetone (Oppenheim, *B. 2*, 571).

Mercury, iodochlorides of. Two iodochlorides of Hg have been isolated. (i) $HgI_2 \cdot 2HgCl_2$ ($= Hg_3I_2Cl_4$). Obtained by dissolving HgI_2 in hot $HgCl_2$, and cooling (Liebig, *S.* 49, 252); also by boiling $HgCl_2$ with excess of I and much water until I vapour is no longer given off (Selmi, *J.* 1855, 417). (ii) $HgICl$. Prepared by heating, in a closed tube at 140° – 160° , HgI_2 , $HgCl_2$, and a little water, until no HgI_2 remains unchanged (Köhler, *B.* 12, 1187). Boullay (*P.* 48, 175) said that $HgICl$ is produced by saturating hot $HgCl_2Aq$ with HgI_2 ; but Köhler found that very little was formed in this way. $HgICl$ forms a citron-yellow crystalline mass, which becomes red after about 12 hours. The red modification forms tetragonal, the yellow forms rhombic, crystals. $HgICl$ is citron-yellow at

$c. 125^\circ$; it melts at $c. 158^\circ$ to a golden-coloured liquid which solidifies at $c. 146^\circ$; it is slightly soluble, with partial decomposition, in hot water, more soluble in alcohol. $HgICl$ may be sublimed, with only slight decomposition, in a stream of HCl , SO_2 , or H_2S . From a solution of $HgICl$ in dilute $HClAq$, H_2S ppt. a yellow solid, probably $HgICl \cdot HgS$ (Köhler, *l.c.*).

Mercury, iodosulphides of; *v. Mercuric sulphide, Combinations*, No. 5, p. 225.

Mercury, nitride of. Hg_3N_2 . (Trimercuramine.) This compound was first isolated by Plantamour (*A.* 40, 115). Ppd. HgO is dried at 40° – 50° , and then heated at 100° in a stream of dry NH_3 , so long as water is evolved (Hirzel, *J.* 1852, 419). Plantamour directed to pass NH_3 over cold HgO , then to heat to 150° in NH_3 , and finally to remove unchanged HgO by HNO_3Aq ; Hirzel found that HNO_3Aq reacts with Hg_3N_2 . Mercury nitride is a brown powder, very explosive, but requires a higher temperature, or a stronger blow, than nitrogen iodide to explode it. Hg_3N_2 is not acted on by cold dilute H_2SO_4Aq ; the hot acid decomposes it. Conc. H_2SO_4 reacts energetically and explosively. Conc. HNO_3Aq forms $Hg(NO_3)_2$ and NH_4NO_3 ; dilute HNO_3Aq forms a white powder; $HClAq$ forms $HgCl_2$ and NH_4Cl . Mixed with KOH and heated, NH_3 and Hg are formed. Moist Hg_3N_2 is slowly decomposed by light; in water it is changed, after 24 hours, to a white powder.

Mercury, oxides of. Two oxides of Hg are known, Hg_2O and HgO ; it is doubtful whether Hg_2O has been obtained free from Hg and HgO . Neither oxide has been gasified, and the mol. w. of neither is known with certainty.

Mercurous oxide. Hg_2O . (Suboxide, or black oxide, of mercury.) This oxide is prepared by adding $NaOHAq$ or $KOHAq$ to solution of a mercurous salt, or to $HgCl$ suspended in water. The best salt to use seems to be $HgNO_2$; it should be dissolved in water with a very little HNO_3 , the solution being made dilute; ppn. with $KOHAq$, and washing with cold water, should be performed in the dark, and the black pp. should be dried in the dark without heating. Guibourt (*A. Ch.* [2] 1, 422) says that Hg_2O cannot be obtained quite free from Hg and HgO ; this is confirmed by Bruns a. O. v. d. Pfordten (*B.* 21, 2010), who assert that Hg_2O oxidises to HgO at the ordinary temperature. Barfoed (*J. pr.* [2] 38, 441) says that the product of the action of $NaOHAq$ on mercurous salts is a mixture of Hg , Hg_2O , and HgO in varying proportions. The descriptions of Hg_2O probably apply to Hg_2O mixed with more or less Hg and some HgO .

Mercurous oxide is a black powder; S.G. 10.69 (Herapath, *P. M.* 64, 821); 8.95 (Karsten, *S.* 65, 394). H.F. $[Hg_2O] = 24,860$ (Thomsen, *Z. P. C.* 2, 21). Hg_2O is decomposed very easily by light or heat, giving HgO and Hg; strongly heated gives Hg and O. Dilute $HClAq$ produces $HgCl$. Hg_2O is soluble in conc. acetic acid. With dilute acids Hg_2O generally yields mercurous salts; with H_3PO_4Aq it gives H_3PO_2Aq and Hg. Boiled with $KIAq$, Hg and $HgI_2 \cdot 2KIAq$ are formed (Berthelot, *J. Ph.* 14, 189). With conc. NH_4ClAq , NH_3 is evolved and Hg and $HgCl_2$ are produced (Pagenstecher, *R. P.* 27, 27; Thompson, *P. M.* [3] 10, 179).

MERCURIC OXIDE. HgO . (*Red oxide of mercury. Red precipitate.*) Mol. w. unknown, as compound has not been gasified. S.G. 11.074 at 15° (Herapath, *R. M.* 64, 321); 11.186 to 11.844 at 4° (Playfair a. Joule, *C. S. Mem.* 8, 84, and *C. J.* 1, 187); 11.29 at 4° *in vacuo* (Le Royer a. Dumas, in Böttger's *Tabellarische Uebersicht der Spec. Gewichte der Körper*, Frankfurt, 1837). S.H. 19° - 52° = .053 (Kopp, *T.* 155, 71); 5° - 98° = .0518 (Regnault, *A. Ch.* [3] 1, 129). H.F. [HgO] = 22,000 (Thomsen, *Z. P. C.* 2, 21). Crystallises in rhombic forms *a:b:c* = .6523:1:9456 (Nordenskjöld, *P.* 114, 621); in monoclinic forms according to Des Cloiseaux (*A. Ch.* [4] 20, 201). C.E. (0° - 100°) .0058 (Playfair a. Joule, *C. J.* 1, 187).

HgO was known to the Arabians in the eighth century; Geber prepared it by calcining the nitrate; and towards the end of the seventeenth century Boyle obtained it by strongly heating Hg in air.

Formation.—By heating Hg to near its B.P. in a loosely covered vessel for a long time.

Preparation.—1. Hg is dissolved in HNO_3Aq , the solution is evaporated to dryness, the residue is powdered and then heated on a sand-tray so long as N oxides are evolved, the temperature being slowly raised, and the heating continued till a porcelain plate held over the vessel shows a slight deposit of Hg . HgO thus prepared forms red lustrous scales.—2. One of the oxychlorides 2HgO.HgCl_2 , and the oxychloride 4HgO.HgCl_2 , when treated with KOH Aq , give red HgO ; another oxychloride 2HgO.HgCl_2 , and also the oxychloride 3HgO.HgCl_2 , give yellow HgO by treatment with KOH Aq . The compound 2HgO.HgCl_2 which yields red HgO is prepared by mixing 1 vol. KHCO_3Aq , free from K_2CO_3 , saturated at 15° , with 8 vols. HgCl_2Aq , also saturated at 15° , stirring with a glass rod till black streaks appear where the rod rubs the glass, pouring off, adding a fresh quantity of the mixed solution, and again stirring. The compound 2HgO.HgCl_2 , which gives the yellow HgO is prepared by stirring a mixture of 1 vol. KHCO_3Aq , saturated at 15° , with 6 to 10 vols. HgCl_2Aq , also saturated at 15° . The compound 4HgO.HgCl_2 is prepared by mixing 1 vol. HgCl_2Aq (saturated at 15°) with a large excess (4 to 6 vols.) KHCO_3Aq (saturated at 15°), and allowing to stand for some time (*cf. Mercury, oxychlorides of*, p. 223).—3. $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or HgCl_2Aq , is poured into KOH Aq ; the pp. is thoroughly washed and dried at 100° - 120° . HgO thus prepared forms a yellow compact solid.

Properties.— HgO exhibits allotropy; it forms heavy, red, crystalline scales, or a somewhat more bulky, amorphous, yellow powder (*v. supra*). HgO is a violent irritant poison. HgO is very slightly soluble in water; 1 pt. dissolves in 200,000 cold water, or in 125,000 pts. if the water is boiled with HgO and then allowed to cool (Wallace, *Chem. Gazette*, 1858, 345). The solution has a metallic taste. Heated to redness, Hg is separated into Hg and O . Heated below the temperature of decomposition, HgO turns black, but recovers its original colour on cooling. HgO is slowly blackened and decomposed to Hg and O by the action of light. There are differences in the reactions of Cl , HgCl_2 , in

alcoholic solution, and oxalic acid, with the two varieties of HgO (*v. Reactions*, Nos. 8, 9, 10).

Reactions.—1. Decomposed by heating to redness, giving Hg and O ; Pelouze (*J. R.* 16, 50) said that yellow HgO is decomposed at a lower temperature than the red variety, but this was not confirmed by Gay-Lussac (*C. R.* 16, 309), nor by Millon (*B. J.* 27, 112). Carnelleya. Walker (*C. J.* 53, 80) found that HgO , ppd. by NaOHAq from HgCl_2Aq , began to give off O at a little above 175° , and that evolution of O became rapid at c. 415° , at which temperature red HgO was formed and decomposed. Myers's results (obtained by measuring vapour pressures of O from HgO ; *B.* 6, 11) agree with those of C. a. W. Debray (*C. R.* 77, 123) found that when a tube containing HgO was sealed, and the whole tube was heated to 440° , the O evolved was almost wholly again absorbed.—2. A mixture of HgO with such easily oxidised bodies as P , S , Sb , detonates when heated more or less violently. Some organic compounds are oxidised by boiling in solution with HgO . SO_2Aq boiled with HgO produces SO_3Aq and Hg .— SnCl_2Aq forms SnCl_4Aq and Hg .—3. HgO is decomposed, rapidly and somewhat violently, by heating with magnesium, in the ratio $\text{HgO}:\text{Mg}$, with formation of MgO and Hg (Winkler, *B.* 23, 128).—4. Heated with sodium, Na amalgam and the compound $\text{Na}_2\text{O.HgO}$ are formed (Beketoff, *B.* 13, 2392); the compound $\text{Na}_2\text{O.HgO}$ is not decomposed by heat, but very quickly by water.—5. HgO dissolves in molten potash. If the KOH is nearly saturated with HgO , allowed to cool slowly, and lixiviated with a little cold water, a heavy violet crystalline powder and a lighter greyish-green powder are obtained. The violet powder is said to consist of $\text{K}_2\text{O.HgO}$, and the greyish powder to contain from 2 to 5 p.c. K_2O ; the S.G. of $\text{K}_2\text{O.HgO}$ is 10.31; it is decomposed at high temperatures, also by continued washing with water, but less completely by alcohol (St. Meunier, *C. R.* 60, 557).—6. According to Foubert (*A. Ch.* [4] 1, 300), saturated solutions of the alkali and alkaline earth haloid compounds are decomposed, with separation of alkali or alkaline oxides, by boiling with HgO (*cf. Melsens, A. Ch.* [3] 26, 220; and H. Rose, *P.* 107, 293). André, however, says that boiling saturated solutions of alkaline earth chlorides react with HgO to form either oxychlorides $x\text{HgCl}_2.y\text{HgO}$, or compounds of HgO with the alkaline chloride (*C. R.* 104, 431; *v. Mercury oxychlorides of*, p. 223; and also *infra, Combinations*, No. 1). According to Jehn (*Ar. Ph.* [8] 1, 97), HgO boiled with KI Aq produces KOH Aq and the double iodide $\text{Hg}_2\text{I}_2\text{.KI}$.—7. HgO reacts with most acids to form mercuric salts HgX_2 ($\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c.).—8. The reaction of chlorine with HgO differs according to the conditions, and the variety of HgO used. Cl scarcely reacts with red crystalline HgO ; with yellow HgO , prepared by ppn. and dried at c. 100° , Cl reacts energetically forming HgCl_2 and O ; with the yellow oxide, dried at 300° and cooled, Cl reacts more slowly, forming Cl_2O and HgCl_2 , or, if water be present, forming HClO Aq and HgO.HgCl_2 (*cf. vol. ii.* pp. 12, 16).—9. An alcoholic solution of mercuric chloride heated with yellow HgO at once produces black oxychloride HgO.HgCl_2 ; the same oxychloride is formed from the red variety of

HgO only after prolonged action of boiling alcoholic HgCl_2 solution.—10. *Oxalic acid solution* reacts with yellow HgO , to form oxalate, in the cold; but the red variety is unchanged when boiled with $\text{H}_2\text{C}_2\text{O}_4$ Aq.

Combinations.—1. With *alkaline earth chlorides*; obtained by the reaction of HgO with solutions of CaCl_2 , BaCl_2 , and SrCl_2 . The compounds $2\text{HgO} \cdot \text{CaCl}_2 \cdot 4\text{H}_2\text{O}$, $\text{HgO} \cdot \text{BaCl}_2 \cdot 6\text{H}_2\text{O}$, and $\text{HgO} \cdot \text{SrCl}_2 \cdot 6\text{H}_2\text{O}$, are described by André (C. R. 104, 431).—2. With *ammonia*, to form $2\text{HgO} \cdot \text{NH}_3 \cdot \text{H}_2\text{O} = \text{NH}_4\text{OH} \cdot 2\text{HgO}$; this compound reacts with acids as a base forming *dimercuri-ammonium salts* (v. MERCURAMMONIUM COMPOUNDS, p. 206).

Mercury, oxybromide of. $3\text{HgO} \cdot \text{HgBr}_2 = \text{Hg}_3\text{O}_4\text{Br}_2$ (*Basic mercuric bromide*.) A yellow, crystalline, powder; obtained by boiling HgBr_2 Aq with HgO , filtering, and allowing to crystallise; or by partial ppt. of HgBr_2 Aq by KOH Aq, and boiling the liquid in contact with the pp. (Lüwig, P. 14, 485; cf. Rammelsberg, P. 55, 248).

For H.F. of oxybromides of Hg v. André, Bl. [2] 41, 274.

Mercury, oxychlorides of. $\text{Hg}_2\text{O}_2\text{Cl}_2$. (*Basic mercuric chlorides*.) Several oxychlorides of Hg are known; they are produced by the reaction of HgO with HgCl_2 Aq, by partial ppt. of HgCl_2 Aq by KOH Aq or NaOH Aq, by mixing KHCO_3 Aq and HgCl_2 Aq in different proportions, and by the reaction of Cl with yellow HgO .

Millon (A. Ch. [3] 27, 253) described oxychlorides obtained by mixing solutions of KHCO_3 (free from K_2CO_3) and HgCl_2 , both saturated at 15° . (i.) $2\text{HgO} \cdot \text{HgCl}_2$; by adding 1 vol. KHCO_3 Aq to 6–10 vols. HgCl_2 Aq; also by adding 1 vol. KHCO_3 Aq to 3 vols. HgCl_2 Aq, stirring till ppt. begins on the sides of the vessel, pouring off the liquid, adding a fresh quantity of the same mixture, and stirring again. The compound obtained by the first process forms a red non-crystalline powder, and yields yellow HgO when acted on by KOH Aq; as obtained by the second process, the compound is a heavy, black, lustrous solid, which yields red HgO with KOH Aq. (ii.) $3\text{HgO} \cdot \text{HgCl}_2$; by mixing equal volumes of the solutions of KHCO_3 and HgCl_2 , and allowing to stand; a golden-yellow crystalline pp., yielding yellow HgO with KOH Aq. (iii.) $4\text{HgO} \cdot \text{HgCl}_2$; by mixing 1 vol. HgCl_2 Aq with 4–6 vols. KHCO_3 Aq, and allowing to stand; a brown crystalline solid, which yields red HgO with KOH Aq.

• Roucher (A. Ch. [3] 18, 372) described seven oxychlorides, containing HgCl_2 and HgO in the ratios 1, $\frac{1}{2}$, 2, 3, 4, 5, and 6; each oxychloride exists, according to Roucher, in two varieties, one derived from and giving red HgO , the other derived from and giving yellow HgO ; some of the oxychlorides also exhibit other differences. Roucher described 15 different oxychlorides. A tabular statement showing the chief differences between the oxychlorides is given by Roucher.

André (C. R. 104, 431) described two oxychlorides, $\text{HgCl}_2 \cdot 3\text{HgO}$ and $2\text{HgCl}_2 \cdot 3\text{HgO}$, obtained by dissolving HgO in boiling CaCl_2 Aq and MgCl_2 Aq, respectively, and pouring the solutions into large quantities of cold water.

The oxychlorides of Hg have been examined more recently by Thümmel (Ar. Ph. 27, 592; v.

abstract in C. J. 56, 1050). f. says that only 5 definite compounds exist, viz., $\text{HgO} \cdot 2\text{HgCl}_2$, $\text{HgO} \cdot \text{HgCl}_2$, $2\text{HgO} \cdot \text{HgCl}_2$, $3\text{HgO} \cdot \text{HgCl}_2$, and $4\text{HgO} \cdot \text{HgCl}_2$. (i) $\text{HgO} \cdot 2\text{HgCl}_2$ is formed in all solutions prepared by dissolving HgO in HgCl_2 Aq, but it is readily decomposed; it is best prepared by heating at 100° 1 pt. HgO (red or yellow), with 10 pts. HgCl_2 , and 60 pts. water, stirring till no further separation of a yellow powder occurs, washing, drying, and then washing with ether (free from alcohol) to remove HgCl_2 . Warm water separates $2\text{HgO} \cdot \text{HgCl}_2$; NaOH Aq ppts. red HgO . (ii) $\text{HgO} \cdot \text{HgCl}_2$ has not yet been obtained pure. (iii) $2\text{HgO} \cdot \text{HgCl}_2$ exists in two varieties; (a) red variety, obtained by mixing solutions of NaHCO_3 and HgCl_2 in the ratio $2\text{NaHCO}_3 : \text{HgCl}_2$; (b) black variety, obtained by heating the red variety when dry, or by adding HgO to hot HgCl_2 Aq, or by mixing equivalent quantities of red HgO and HgCl_2 in cold water, or by treating $3\text{HgO} \cdot \text{HgCl}_2$ with cold HgCl_2 Aq. (iv) $3\text{HgO} \cdot \text{HgCl}_2$ is a yellow pp. obtained by adding alkaline carbonate (normal or acid) to HgCl_2 Aq, avoiding excess of the carbonate, also by treating freshly pptd. yellow HgO with HgCl_2 Aq (this preparation is yellow and yields yellow HgO with KOH Aq), also by treating washed red HgO with HgCl_2 Aq (this preparation is reddish yellow and yields red HgO by KOH Aq). (v) $4\text{HgO} \cdot \text{HgCl}_2$ is obtained as a brown amorphous powder, by adding KHCO_3 Aq to HgCl_2 Aq, in the ratio 30 to 35 $\text{KHCO}_3 : \text{HgCl}_2$; it is also obtained, as reddish-brown crystalline plates, by shaking HgCl_2 Aq with red HgO in the ratio $\text{HgCl}_2 : 6\text{HgO}$; both varieties give yellow HgO by KOH Aq. All these oxychlorides yield sublimates containing HgCl and HgCl_2 when heated.

For H.F. of oxychlorides of Hg v. André, Bl. [2] 41, 274.

• **Mercury, oxycyanides of; v. CYANIDES**, vol. ii. p. 342.

Mercury, oxyfluoride of. $\text{HgO} \cdot \text{HgF}_2 \cdot \text{H}_2\text{O}$. (*Basic mercuric fluoride*.) A yellow crystalline solid; obtained by dissolving freshly pptd. HgO in HFA Aq, and digesting the solution with HgO , or evaporating the solution (Finkener, P. 110, 628). The oxyfluoride is also obtained by heating $\text{HgF}_2 \cdot 2\text{H}_2\text{O}$ (q. v. p. 210) to 80° (F.). Heated above 100° , the oxyfluoride gives off H_2O and HF ; it is decomposed by water with separation of HgO .

Mercury, oxyiodide of. $3\text{HgO} \cdot \text{HgI}_2$. (*Basic mercuric iodide*.) A yellowish-brown solid; obtained by melting together HgO and HgI_2 in the ratio $3\text{HgO} : \text{HgI}_2$, also by digesting HgI_2 with dilute KOH Aq (Rammelsberg, P. 48, 182).

• **Mercury, oxysulphides of.** Oxysulphides of Hg have been described; but according to Pollock (D. 22, 2859) none has been isolated, and the existence of any is very improbable.

Mercury, phosphide of. No phosphide of Hg has been isolated with certainty. By passing P hydride, prepared by boiling amorphous P with KOH Aq, into HgCl_2 Aq, several compounds have been obtained. Aschan (Chem. Zeitung, 10, 82, 102) describes a yellow compound $3\text{Hg}_2\text{P}_2 \cdot 7\text{HgCl}_2$, a red compound $4\text{Hg}_2\text{P}_2 \cdot 5\text{HgCl}_2$, and a black compound $\text{Hg}_2\text{P}_2 \cdot \text{HgCl}_2$. A compound probably $2\text{PH}_3 \cdot 6\text{Hg}_2\text{O}$ is said by Aschan (loc. cit.) to be formed by passing P hydride over Hg_2O . The pp.

formed when P hydride is passed into $\text{Hg}(\text{NO}_3)_2\text{Aq}$ are probably mixtures of different compounds of Hg, P, and HNO_3 (A.). Most of the foregoing compounds are readily decomposed, some explosively, by warming.

Mercury, salts of. Hg forms two series of salts; *mercurous salts* corresponding with Hg_2O , and *mercuric salts* corresponding with HgO . The former are obtained sometimes by dissolving Hg_2O in acids, sometimes by dissolving Hg in acids and digesting with excess of Hg, and in some cases by double decomposition from the nitrate; the mercuric salts are obtained by dissolving HgO or HgCO_3 in acids, or by double decomposition from the nitrate. The mercurous salts have the composition Hg_2X , where $\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, &c.; the mercuric salts have the composition HgX_2 . The mercuric salts are more stable, as a class, than the mercurous salts. The normal mercurous salts are generally decomposed by water into a basic salt, which separates, and an acid salt, which goes into solution. Many basic salts and a large number of double salts are known. The salts of Hg, as a class, act as violent and irritating poisons. The principal salts of Hg are the following (v. CARBONATES, NITRATES, SULPHATES, &c.): *antimonates, arsenates and -ites, bromates, carbonates, chlorates and perchlorates, chromates, iodates and periodates, molybdates, nitrates and -ites, phosphates, selenates and -ites, sulphates and -ites, tantalates, thiosulphates, tungstates, vanadates.*

Mercury, selenide of. HgSe . Small quantities of more or less pure HgSe occur native in the Harz, accompanying PbSe . HgSe is produced by strongly heating together Hg and Se, and subliming at a higher temperature; forms grey, metal-like, lustrous laminae; dissolved by *aqua regia* with formation of Hg selenite, slowly changed to the same compound by boiling conc. nitric acid (Uelsmann, A. 116, 126; cf. Little, A. 112, 211). HgSe is also formed by passing H_2Se for a long time into HgCl_2Aq ; the white pp. of 2HgSe.HgCl_2 at first produced is changed to black HgSe . S.G. of natural HgSe is 7.1 to 7.4; S.G. of artificially prepared HgSe is 8.877.

Combinations.—1. With *mercuric chloride*, to form 2HgSe.HgCl_2 ; a white pp. formed by adding H_2Se , or K_2Se , to excess of HgCl_2Aq .—2. With *mercuric oxide*, to form 2HgSe.HgO ; a black powder formed by treating 2HgSe.HgCl_2 with NaOHAq . Decomposed by heat, yielding sublimates of HgSe and Hg (Uelsmann, A. 116, 126).

Mercury, selenochloride of. $\text{Hg}_2\text{Se}_2\text{Cl}_2$; v. *Mercury, selenide of, Combinations*, No. 1.

Mercury, selenosulphide of. A mineral approaching the composition $\text{HgSe}.4\text{HgS}$ is found near San Onofre in Mexico; it is known as *onofrite*.

Mercury, selenocyanides of. HgSeCy and $\text{Hg}(\text{SeCy})_2$; v. vol. ii. p. 848.

Mercury, silicofluorides of. Two are known, $\text{Hg}_2\text{SiF}_6.2\text{H}_2\text{O}$ and $\text{HgSiF}_6.6\text{H}_2\text{O}$.

MERCURIUS SILICOFUORIDE, $\text{Hg}_2\text{SiF}_6.2\text{H}_2\text{O}$. Clear prismatic crystals; obtained by dissolving Hg_2CO_3 in $\text{H}_2\text{SiF}_6\text{Aq}$, evaporating, washing with a little water, and pressing between paper (Finkener, P. 111, 246; cf. Berzelius, P. 1, 200).

MERCURIUS SILICOFUORIDE, $2\text{HgSiF}_6.6\text{H}_2\text{O}$. Obtained by dissolving HgO in $\text{H}_2\text{SiF}_6\text{Aq}$, evaporating till yellow needles ($\text{HgSiF}_6.\text{H}_2\text{O}$) begin to separate, and then allowing to stand at a temperature not above 15° . Forms clear, colourless, rhombohedral crystals; very unstable; deliquescent in air, and efflorescent over H_2SO_4 ; composition doubtful (Finkener, P. 111, 246). The compound $\text{HgSiF}_6.\text{H}_2\text{O}$ (Finkener) was described by Berzelius (P. 1, 200) as the normal salt.

Mercury, sulphides of. Two are known, Hg_2S and HgS ; the latter reacts towards the alkali sulphides as an acidic sulphide, it also combines with many Hg compounds to form double compounds.

MERCURIUS SULPHIDE, Hg_2S . This sulphide is best prepared, according to Berzelius, by dropping mercurous acetate solution into Na or NH_4 sulphide solution (cf. Brande, Q. J. S. 18, 292). HgNO_3Aq should not be used, as the HNO_3 produced oxidises the Hg_2S . Hg_2S is a black powder, easily decomposed by heat to HgS and Hg. According to Barfod (*Bl.* [2] 3, 183) the substance described as Hg_2S always contains some Hg, however it may be prepared.

MERCURIUS SULPHIDE, HgS . Mol. w. uncertain. H.F. [HgS] - 8,220 (Thomsen, Z. P. C. 2, 21). This compound exists in two forms: a black amorphous pp., and a red crystalline body known as *vermilion* or *cinnabar*.

Occurrence.—In Illyria, Spain, Bohemia, Ural mountains, China, Japan, Mexico, California, Chili, and Peru.

Formation.—1. By rubbing or heating together 1 pt. S and $6\frac{1}{2}$ pts. Hg.—2. By adding H_2S or an alkaline sulphide, to solution of a mercuric salt.—3. By digesting Hg with an alkaline polysulphide.—4. By subliming a mixture of S and HgO or HgSO_4 .

Preparation.—1. Amorphous black mercuric sulphide is prepared by passing excess of H_2S into slightly acidified HgCl_2Aq or $\text{Hg}(\text{NO}_3)_2\text{Aq}$, washing the pp. thoroughly with dilute HNO_3Aq and then with water, and drying at a low temperature.—2. Red crystalline mercuric sulphide (vermilion) is prepared in different ways. (a) A mixture of 6 pts. Hg and 1 pt. S is heated till combination occurs (attended generally with production of heat and light and partial projection of the mass); the product is powdered, mixed with a small quantity of S, and heated for some hours in a hard glass flask, sunk in sand in a wind-furnace; the flask is loosely closed by a charcoal stopper and is arranged so that the upper part is kept comparatively cold; red HgS sublimes on to the neck of the flask. The HgS is purified by grinding, boiling with KOHAg , and washing with water. (b) Black amorphous HgS is heated with an alkaline persulphide. This may be done by triturating 100 pts. Hg with 88 pts. S for some hours, till black HgS is produced, heating with 25 pts. KOH in 180–250 pts. water to 45° – 50° for several hours (the water being replaced as it evaporates, and the mass being stirred from time to time) until reddening begins, after which the temperature is maintained at 45° till the whole is bright-red. The red HgS is washed, and any Hg present is removed by levigation (Brunner, P. 15, 598; cf. Döbereiner, S. 61, 699).

Firmenich, D. P. J. 172, 370; Liebig, A. 5, 289; 7, 49; Raab, N. R. P. 24, 89). (c) HgCl_2Aq is poured into excess of dilute NH_3Aq ; to the pp. of NH_4HgCl thus produced is added conc. $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ in quantity rather more than sufficient to dissolve the pp., and the whole is heated for some time to $70^\circ\text{--}80^\circ$ (Hausmann, B. 7, 1746). For details of the manufacture of *Vermilon* v. DICTIONARY OF APPLIED CHEMISTRY.—8. Colloidal mercuric sulphide, soluble in water, is obtained by ppg. a dilute solution of a mercuric salt by H_2S , and washing with water or dilute H_2SAq for a long time (Winssinger, B. [2] 49, 452).

Properties.—The black sulphide is an amorphous, heavy powder; heated in a closed vessel, it yields a sublimate of red HgS ; heated in air, Hg sublimes and SO_2 is formed; it is not acted on by dilute acids. The red sulphide crystallises in hexagonal forms, $\text{ac} = 1:1:145$; S.G. 8.1 to 8.99; polarises light; blackens by exposure to light (v. Heumann, B. 7, 750); heated to the sublimation-temperature, red HgS is changed to the black variety (Fuchs, P. 81, 581). Mitscherlich (A. 12, 168) found V.D. of HgS at 670° to be 85.3; V. and C. Meyer found V.D. at 1560° to be 78; the formula HgS requires V.D. 116; a mixture of $\text{Hg} + \text{Hg} + 2\text{S}$ requires V.D. 77.3. The red sulphide reacts with acids more slowly than the black variety. The colloidal sulphide is soluble in water, forming a solution which is black and opaque when conc., but brown, with a greenish tint by reflected light, when dilute; a very dilute solution may be boiled till all H_2S is expelled, or kept for some time, without change.

Reactions.—1. Heated in a closed vessel, HgS sublimes.—2. Heated in air, SO_2 is formed, and Hg sublimes.—3. Heated with solid alkalis or alkaline carbonates, Hg sublimes and alkaline sulphide remains.—4. Heated with iron, tin, antimony, copper, zinc (and some other metals), a metallic sulphide and Hg are produced; HgS is decomposed by heating with finely divided Cu and water (v. Heumann, B. 7, 1388, 1486).—5. Digested for some time with iodine in KIAq , HgS is decomposed with formation of $\text{HgI}_2 \cdot 2\text{KI}$ and separation of S (Wagner, J. pr. 98, 23).—6. HgS is decomposed to Hg and SO_2 by heating with lead monoxide, Pb being separated.—7. HgS is scarcely attacked by dilute acids; conc. nitric acid produces $\text{Hg}(\text{NO}_3)_2$, mixed with HgSO_4 ; HNO_3Aq S.G. c. 1.2 produces a white compound $2\text{HgS} \cdot \text{Hg}(\text{NO}_3)_2$.—8. According to Bolley (A. 75, 239) HgS is at once decomposed by an ammoniacal solution of silver nitrate, with formation of a mercurammonium salt and Ag_2S .—9. HgS is insoluble in caustic soda or sodium monosulphide solution; but it dissolves in a mixture of the two, i.e. in sodium hydrosulphide solution. This solution contains a sulpho-salt (sulphohydrargyrate of sodium). The solution is readily obtained by adding KOHAq to ppd. HgS , and passing in H_2S (excess of H_2S causes reppn. of HgS). On evaporation, white crystals $\text{HgS} \cdot \text{K}_2\text{S} \cdot 5\text{H}_2\text{O}$ separate, mixed with KOH ; these crystals are decomposed by water (Weber, P. 97, 76; cf. Brunner, P. 15, 596). By ppg. HgCl_2Aq with NH_3 sulphide, and adding KOHAq , a solution is obtained, which, on evaporation, yields KCl , and then a sulpho-salt mixed with KOH .

Vol. III.

According to Schneider (P. 127, 468) the crystals of the sulpho-salt, when kept for some years in KOHAq , form six-sided, lustrous, olive-green tablets having the composition $2\text{HgS} \cdot \text{K}_2\text{S}$.

Combinations.—1. With alkali sulphides; v. supra, Reactions No. 9.—2. Forms a compound with hydrogen sulphide; $81\text{HgS} \cdot \text{H}_2\text{S}$. Produced in solution by passing H_2S into HgS suspended in boiled water (Linder a. Picton, C. J. Proc. 1890, 49).—3. With cuprous chloride to form $2\text{HgS} \cdot \text{Cu}_2\text{Cl}_2$; a yellow solid, obtained by boiling HgS with CuCl_2Aq and HClAq , and removing S by CS_2 ($78\text{HgS} + 2\text{CuCl}_2 = 2\text{HgS} \cdot \text{Cu}_2\text{Cl}_2 + \text{HgCl}_2 + \text{S}$). This compound is decomposed by boiling conc. HClAq with evolution of a little H_2S and formation of Cu_2Cl_2 and HgCl_2 in solution; dilute hot $\text{H}_2\text{SO}_4\text{Aq}$ has no action, but with boiling conc. H_2SO_4 , HCl and SO_2 are evolved and a compound of HgSO_4 and HgS is formed. NaOHAq produces NaCl , HgS , and Cu_2O (v. Heumann, B. 7, 1390).—4. With mercuric chloride, and also with mercuric bromide, to form compounds $2\text{HgS} \cdot \text{HgX}_2$ ($\text{X} = \text{Cl}$ or Br). These sulphohaloid compounds are formed (a) by passing H_2S into excess of HgCl_2Aq or HgBr_2Aq , (b) by digesting freshly ppd. HgS with boiling HgCl_2Aq or HgBr_2Aq (H. Rose, P. 13, 69), (c) by adding HCl (or HBr), or solution of a metallic chloride (or bromide), to HgS dissolved in mercuric acetate solution (Palm, C. C. 1863, 120), (d) by heating HgS with 8-10 parts HgCl_2 or HgBr_2 , till the whole melts, and washing the cold mass with boiling water (Schneider, P. 115, 167). The compounds are yellow-white crystalline powders; decomposed by slow heating to HgS and HgX_2 ; decomposed by alkali solutions, but not by HNO_3Aq or $\text{H}_2\text{SO}_4\text{Aq}$ (cf. Barfoed, J. pr. 93, 230).—5. With mercuric iodide to form the sulpho-iodide $\text{HgS} \cdot \text{HgI}_2$; a yellow solid obtained by digesting HgI_2 with less H_2SAq than suffices for complete decomposition (H. Rose, P. 13, 69); also by ppg. HgO and HgI_2 in HClAq by a small quantity of H_2S (Rammelsberg, P. 48, 175); also by saturating HgI_2 in HIAq with H_2S , and diluting (Kekulé). Palm (C. C. 1863, 121) says that the yellow-red pp. obtained by adding HIAq , or a solution of an alkali iodide, to HgS dissolved in mercuric acetate solution, has the composition $2\text{HgS} \cdot \text{HgI}_2$.—6. With mercuric fluoride, to form the sulphofluoride $2\text{HgS} \cdot \text{HgF}_2$; obtained by passing a little H_2S into HgF_2 dissolved in HFAq (H. Rose, P. 13, 69).—7. With mercuric sulphate, to form several compounds, the chief of which are (1) $\text{HgSO}_4 \cdot \text{HgS}$, (2) $\text{HgSO}_4 \cdot 2\text{HgS}$, and (3) $\text{HgSO}_4 \cdot 3\text{HgS}$. These compounds are obtained, (1) by treating red HgS with warm $\text{H}_2\text{SO}_4\text{Aq}$ (Palm, J. 1862, 220); (2) by treating $2\text{HgS} \cdot \text{HgNO}_3$ (obtained by passing a little H_2S into $\text{Hg}(\text{NO}_3)_2\text{Aq}$ with $\text{H}_2\text{SO}_4\text{Aq}$ (Barfoed, J. 1864, 282; Kessler, A. Ch. [2] 6, 615); (3) by adding $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$ to $\text{Hg}(\text{NO}_3)_2\text{Aq}$ and removing S by washing with CS_2 (Spring, A. 199, 116; Wackenroder, A. 60, 190).—8. With mercuric nitrate, to form $2\text{HgS} \cdot \text{Hg}(\text{NO}_3)_2$; a white solid, obtained by passing a little H_2S into $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or by digesting freshly ppd. HgS with $\text{Hg}(\text{NO}_3)_2\text{Aq}$, or by ppg. a solution of HgS in mercuric acetate by HNO_3Aq or alkali nitrate solution (H. Rose, Barfoed, Palm, l.c.). By heating HgS with HNO_3Aq , S.G. 1.2, to 120° in a closed tube, Gram-p

(*J. pr.* [3] 14, 299) obtained a white crystalline mass of $6\text{HgS.HgO.2Hg(NO}_3)_2.12\text{H}_2\text{O}$.

MERCURY COMPOUNDS, ORGANIC. Mercury forms compounds with two identical alcohol radicles, or with one alcohol radicle and one acid residue. Compounds of mercury with two different alcohol radicles appear to split up at the moment of their formation, *e.g.* $2\text{HgEtMe} = \text{HgMe}_2 + \text{HgEt}_2$ (Frankland, *A.* 111, 57).

Mercury dimethide $\text{Hg}(\text{CH}_3)_2$. *Mercury dimethyl.* Mol. w. 230. V.D. 8.29 (calc. 7.97). (98°–96°).

Formation.—1. When mercury is exposed with MeI to sunlight for a week, crystalline CH_3HgI is formed (Frankland, *A.* 85, 361). When this body is distilled with KOH, lime, or KCl, mercury dimethide passes over as a heavy liquid which may be purified by washing with water and rectifying over CaCl_2 (Buckton, *Pr.* 9, 91; *A.* 108, 103).—2. By the action of sodium-amalgam on MeI (10 pts.) in presence of acetic ether (1 pt.) (Frankland & Duppa, *C. J.* 17, 415; *A.* 180, 105).

Properties.—Colourless oil, with faint but mawkish taste. Insol. water, *v.* sol. alcohol and ether. Dissolves phosphorus, resins, and caoutchouc. Very inflammable, burning with a bright flame.

Reactions.—1. Iodine forms CH_3HgI and methane. Bromine acts in like manner.—2. SnCl_4 forms a crystalline compound which is decomposed by water with formation of CH_3HgCl .—3. Conc. HClAq gives methane and CH_3HgCl .—4. Conc. H_2SO_4 gives methane and $(\text{CH}_3\text{Hg})_2\text{SO}_4$.—5. PCl_5 gives CH_3HgCl .—6. KMnO_4 oxidises it to $\text{CH}_3\text{Hg.OH}$ (Seidel).

Mercuric chloro-methide CH_3HgCl . [170°] (Seidel, *J. pr.* [3] 29, 135). S.G. 4.063 (Schröder, *B.* 12, 563). Formed from HgMe_2 by the action of HCl. Laminæ.

Mercuric iodomethide CH_3HgI . [143°]. From MeI and Hg in sunlight (Frankland). Formed also by heating HgMe_2 with HgI_2 . Small nacreous laminæ (from ether), insol. water, *m.* sol. alcohol, *v.* sol. ether and MeI. Slightly volatile, emitting an unpleasant odour, and leaving a persistent nauseous taste. May be sublimed.

Mercuric nitromethide CH_3HgNO_2 . [100°]. From an alcoholic solution of CH_3HgI and AgNO_3 . Nacreous laminæ, *v.* sol. water, *sl.* sol. alcohol. Its solution is not pptd. by KOH or barytes-water, but HCl and soluble chlorides ppt. CH_3HgCl (Strecker, *A.* 92, 79).

Mercuric acetomethide $\text{CH}_3\text{Hg.OAc}$. [143°]. Obtained by heating HgMe_2 with acetic acid at 180° (Otto, *Z.* [9] 6, 25). Thin tables,

with very offensive odour, nearly insol. boiling water and cold HIOAc .

Mercuric chloro-methylo-iodide $\text{CH}_2\text{Cl.HgI}$. [129°]. Obtained by boiling $\text{CH}_2\text{I.HgI}$ with alcoholic HgCl_2 (Sakurai, *C. J.* 41, 360). Silky plates (from alcohol). Decomposed by iodine into methylene chloro-iodide and HgCl_2 .

Mercuric iodo-methylo-iodide $\text{CH}_2\text{I.HgI}$. [109°]. Formed by leaving mercury and a little mercurous iodide in contact with methylene iodide in a sealed tube for several days (Wanklyn & Von Than, *C. J.* 12, 258; Sakurai, *C. J.* 37, 658). White crystals (from CH_2I_2); insol. water, cold alcohol, ether, chloroform, EtI, and benzene; *sl.* sol. boiling alcohol; *v.* sol. methylene iodide. When heated with iodine dissolved in aqueous KI it is decomposed into CH_2I_2 and HgI_2 . Chlorine and bromine act in like manner. When heated with HClAq it is reduced to CH_3HgI .

Di-mercuric methylene-di-iodide $\text{CH}_2(\text{HgI})_2$. [c. 230°]. Obtained by exposing a mixture of an ethereal solution of methylene iodide with a little HgI_2 and an excess of mercury to sunlight (Sakurai, *C. J.* 39, 487). Formed also by the action of mercury on $\text{CH}_2\text{I.HgI}$. Yellowish crystalline powder, insol. all ordinary solvents, *sl.* sol. hot methylene iodide. When heated with dilute HClAq or with KIAq it yields CH_3HgI . Iodine forms HgI_2 and methylene iodide.

Mercuric methenyl-tri-iodide $\text{CH}(\text{HgI})_3$. From iodoform, mercury, and alcohol, by exposure to sunlight (Sakurai, *C. J.* 39, 488). Yellow mass, insol. ordinary solvents and in CH_2I_2 . Gives iodoform when treated with iodine.

Mercuric diethide HgEt_2 . Mol. w. 258. (159°). S.G. 2.46. V.D. 9.97 (calc. 9.4). Strecker (*C. R.* 39, 57; *A.* 92, 97) by acting on EtI with mercury obtained the compound EtHgI . Dünhaupt (*Chem. Gaz.* 1854, 263; *A.* 92, 879) obtained the corresponding EtHgCl and EtHgBr by decomposing bismuth triethide with HgCl_2 or HgBr_2 . Buckton (*A.* 109, 218; *C. J.* 16, 17) obtained HgEt_2 by the action of ZnEt_2 on HgCl_2 ; and, lastly, Frankland and Duppa showed that mercuric diethide can be more easily obtained by the action of sodium-amalgam on EtI in presence of acetic ether. The acetic ether remains in undiminished quantity at the end of the process; but nevertheless its presence is essential.

Preparation.—Ethyl iodide (10 pts.) is mixed with EtOAc (1 pt.) and poured upon $\frac{1}{2}$ p.c. sodium-amalgam, the flask being shaken and cooled in water. When separation of NaI has rendered the liquid pasty it is distilled off from a water-bath and shaken with fresh amalgam. Finally it is mixed with water, and the oil dried over CaCl_2 and rectified.

Properties.—Transparent colourless liquid, with faint ethereal odour; insol. water, *sl.* sol. alcohol and ether. Very poisonous. Burns with smoky flame. Takes fire in chlorine.

Reactions.—1. Acts violently on bromine and iodine, forming EtHgBr and EtHgI (Buckton, *A.* 112, 220).—2. Alcoholic HgCl_2 forms EtHgCl .—3. Conc. HClAq forms ethane and EtHgCl .—4. H_2SO_4 gives ethane and $(\text{EtHg})_2\text{SO}_4$.—5. Sodium forms a bulky grey spongy mass, which

takes fire in air and violently decomposes when heated.—6. Heated with finely granulated zinc it yields ZnEt_2 and mercury (Frankland & Duppa, *C. J.* 17, 29). *Cadmium* forms CdEt_2 . *Bismuth* gives BiEt_3 .—7. Mercuric ethide is decomposed when heated at 150° with copper, iron, silver, or gold; but ethides of these metals are not formed. 8. KMnO_4 forms EtHgOH .—9. When heated with PCl_5 it forms PEtCl_2 .—10. *Iodoform* at 90° gives acetylene and ethylene (Suida, *M.* 1, 716).

Mercuric chloro-ethide EtHgCl . [190°] (Seidel). S.G. 3.48. Formed by the action of HgCl_2 on BiEt_3 ; by treating HgEt_2 with alcoholic HgCl_2 , and by the action of HgCl_2 on ZnEt_2 . Ppd. by adding NaCl to an aqueous solution of EtHgNO_3 . Obtained also by treating EtHgOH with HCl . Light iridescent laminae (from alcohol). Nearly insol. water, sl. sol. ether, v. sol. boiling alcohol. Sublimes at 40° . With Ag_2CO_3 it gives $(\text{EtHg})_2\text{CO}_3$, which crystallises with difficulty and is easily decomposed by heat and by acids. Ag_3PO_4 gives a very soluble phosphate (Dünhaupt).

Mercuric iodo-methide EtHgI . Formed by the action of mercury on EtI in diffused daylight. Decomposed by direct sunlight (Strecker, *A.* 92, 75). Shining laminae; insol. water, sol. alcohol and ether. Sublimes at 100° . Dissolves without change in aqueous NH_3 or KOH . With ZnEt_2 it yields ZnI_2 and HgEt_2 .

Mercuric ethyl-hydroxide EtHgOH . Obtained by adding moist Ag_2O to a boiling alcoholic solution of EtHgCl , filtering, and evaporating *in vacuo*. Strongly alkaline liquid, which blisters the skin. V. sol. water. Decomposes ammonium salts with expulsion of NH_3 . It does not liberate KOH or MgO from their salts, but it ppts. salts of Al , Zn , Sn , Cu , Au , and Pt . With a large excess of H_2S it forms a white pp. turning through orange to black. With metallic zinc it forms ZnEt_2 . With acids it forms crystalline salts; e.g. HCl yields EtHgCl .

Mercuric bromo-ethide EtHgBr . *Mercuric ethyl-bromide*. Formed from BiEt_3 and HgBr_2 , or by treating EtHgOH with HBr (Dünhaupt, *A.* 92, 379). Resembles EtHgCl .

Mercuric ethyl-cyanide EtHgCy . Formed by saturating an alcoholic solution of EtHgOH with HCy . Crystallises readily; v. sol. alcohol and ether. Very volatile. Gives off a repulsive odour when heated.

Mercuric ethyl-nitrate EtHgNO_3 . *Mercuric nitro-ethide*. From EtHgI and AgNO_3 . Colourless prisms, v. e. sol. water, m. sol. alcohol (Strecker).

Mercuric ethyl-sulphate $(\text{EtHg})_2\text{SO}_4$. Formed from EtHgCl and Ag_2SO_4 . Shining laminae (from alcohol).

Mercuric ethyl-sulphide $(\text{EtHg})_2\text{S}$. Obtained by adding ammonium sulphide to an alcoholic solution of EtHgCl . Yellowish-white powder, v. sol. alcohol, ether, and CS_2 . The alcoholic solution is decomposed by evaporation, leaving HgS .

Mercuric ethyl-acetate EtHgOAc . [175°]. Obtained by dissolving HgEt_2 in HOAc (Otto, *Z.* 1870, 25).

Mercuric dipropyl HgPr_2 . [190°] (C.); [180°] (Sehtscherbakoff, *J. R.* 13, 353). S.G. 1.2-2.14. Formed by the action of propyl iodide on sodium-amalgam in presence of acetic ether (Cahours,

C. R. 76, 133, 1383). Oil, sl. sol. alcohol, v. sol. ether. With iodine and bromine it forms products which may be crystallised from alcohol. The effect of small additions of HgPr_2 of $\text{Hg}(\text{C}_2\text{H}_5)_2$, of $\text{Hg}(\text{C}_2\text{H}_5)_4$, and of HgPh_2 on the freezing-point of ethylene bromide has been studied by Louise and Roux (*C. R.* 107, 600).

Mercuric di-isobutyl $\text{Hg}(\text{CH}_2\text{Pr})_2$. [206°]. S.G. 1.835. Obtained by treating a mixture of isobutyl iodide and acetic ether with 2 p.c. sodium-amalgam (Cahours). Colourless liquid. Iodine forms $\text{CH}_2\text{Pr.HgI}$, whence Ag_2O forms $\text{CH}_2\text{Pr.HgOH}$. Bromine acts in like manner.

Mercuric di-isoamyl $\text{Hg}(\text{C}_4\text{H}_9)_2$. S.G. 1.666. From isoamyl iodide (5 pts.), acetic ether (1 pt.), and sodium-amalgam (Frankland & Duppa, *A.* 130, 110). Colourless oil, decomposed on distillation even *in vacuo*. May be distilled with steam. Insol. water, v. sl. sol. alcohol, v. sol. ether. With chlorine it forms dense fumes of $\text{C}_4\text{H}_9\text{HgCl}$. It reacts with great violence with bromine and iodine. With an alcoholic solution of HgCl_2 it readily forms $\text{C}_4\text{H}_9\text{HgCl}$ [86°], which crystallises from alcohol in hair-like needles. An ethereal solution of $\text{Hg}(\text{C}_4\text{H}_9)_2$, treated first with an alcoholic solution of iodine and then with solid iodine forms isoamyl iodide and $\text{C}_4\text{H}_9\text{HgI}$ [122°], which crystallises from alcohol in pearly scales. With zinc at 130° $\text{C}_4\text{H}_9\text{HgI}$ forms zinc isoamyl and zinc-amalgam.

Mercuric-di-octyl $\text{Hg}(\text{C}_8\text{H}_{17})_2$. S.G. 1.842. Prepared by the action of sodium-amalgam on octyl iodide in presence of a little acetic ether (Eichler, *B.* 12, 1880). Liquid. Insol. water, sol. alcohol, ether, and C_6H_6 . Decomposes at 200° into Hg and hexadecane (dioctyl).

Mercuric octyl-iodide $\text{C}_8\text{H}_{17}\text{HgI}$: white silky pp. Prepared by the action of an alcoholic solution of iodine on mercury-dioctyl.

Mercuric octyl-chloride $\text{C}_8\text{H}_{17}\text{HgCl}$. White pp. Prepared by the action of mercuric chloride on mercury-dioctyl.

Mercuric octyl-hydroxide $\text{C}_8\text{H}_{17}\text{HgOH}$. [75°]. Prepared by the action of silver oxide on an alcoholic solution of mercury-dioctyl (Eichler, *B.* 12, 1881). Yellow leaflets. Insol. cold, sl. sol. hot, water, v. sol. alcohol. Alkaline.

Mercuric allylo-iodide $\text{C}_3\text{H}_5\text{HgI}$. [135°]. S. (CS.) 18.7 at 49° . Formed by shaking allyl iodide with mercury, and extracting the resulting yellow mass with hot alcohol or ether (Zinin, *A.* 96, 363; cf. Linnemann, *A.* 140, 180). It is best to mix the allyl iodide with an equal volume of alcohol (Oppenheim, *B.* 4, 670). Silvery scales, which turn yellow on exposure to light, especially on drying. It even turns yellow in the dark. Sublimes at 100° . Sl. sol. cold alcohol, nearly insol. water. Decomposes above its melting-point. AgNO_3 added to its alcoholic solution ppts. all the iodine as AgI . Moist Ag_2O ppts. AgI and the filtrate on evaporation leaves a strongly alkaline syrupy mass which forms salts with acids. HI easily decomposes it, forming HgI_2 and propylene. Iodine forms HgI_2 and allyl iodide (Linnemann, *A.* 133, 133; *Suppl.* 3, 262). PBr_3 , acetyl chloride, and BaCl_2 have no action on mercury allyl-iodide. On shaking it with a solution of ZnEt_2 in ether an energetic reaction sets in, the products being mercury, ZnI_2 , diallyl, and HgEt_2 . A solution

of KCy acts quickly in the cold, forming diallyl, mercury, HgCy_2 , and KI ; if in distilling off the diallyl the distillation is not stopped in time an explosion occurs. Aqueous KI at 100° forms mercury, diallyl, and KHgI . The mercury allyl compounds attack the skin, producing blisters which appear after the lapse of 7 hours. The compound $\text{C}_6\text{H}_5\text{HgCl}$ obtained by the action of HCl on the hydroxide is sparingly soluble (Krasowsky, *Z.* 6, 527).

Mercuric propargyl iodide $\text{C}_3\text{H}_3\text{HgI}$. From propargyl iodide and mercury (Henry, *B.* 17, 1182). Small yellowish crystalline masses.

Mercuric diphenyl $\text{Hg}(\text{C}_6\text{H}_5)_2$. [120°]. (above 800°). S.G. 2.318. Formed by heating a mixture of bromo-benzene, benzene, HgCl_2 , and sodium (Michaelis a. Reese, *B.* 16, 2876). Prepared by boiling for some time a solution of bromo-benzene (10 pts.) in an equal volume of xylene with 2.7 p.c. sodium amalgam and a little acetic ether (1 pt.). The product is recrystallised from benzene (Dreher a. Otto, *Z.* [2] 4, 685; 6, 9; *A.* 154, 93). Small white needles or prisms, turning yellow in daylight. Insol. water, v. sol. chloroform, CS_2 , and benzene, m. sol. ether and boiling alcohol. May be sublimed. Partly decomposed on distillation into mercury, diphenyl, benzene, and charcoal.

Reactions.—1. Dry HCl gives benzene and HgCl_2 . HI , nitric acid, HBr , and H_2SO_4 act in like manner.—2. When melted with sulphur (2 at.) the products are HgS and phenyl mercaptan.—3. Iodine (2 at.) in alcoholic or CS_2 solution forms PhHgI and iodo-benzene. Excess of iodine forms HgI_2 and iodo-benzene.—4. Chlorine forms PhHgCl and chloro-benzene. Br acts in like manner.—5. Glacial acetic acid yields benzene and PhHgOAc .—6. Aluminium foil at 130° forms AlEt_3 (230°) (Friedel a. Crafts, *A. Ch.* [6] 14, 460).—7. Alcoholic HgCl_2 at 100° gives PhHgCl .—8. When boiled with sodium, benzene and sodium-amalgam are formed.—9. SO_2 gives mercuric benzene sulphonate (Otto, *J. pr.* [2] 1, 179).—10. *Allyl iodide* forms diallyl, diphenyl, and PhHgI (Suida, *M. I.* 715).—11. $\text{C}_6\text{H}_5\text{SO}_2\text{Cl}$ at 160° forms $\text{C}_6\text{H}_5\text{SO}_2\text{C}_6\text{H}_5$ and PhHgCl (Otto, *B.* 18, 246).—12. $\text{COCl}_2\text{CO}_2\text{Et}$ forms phenylglyoxylic ether (Claisen a. Morley, *B.* 11, 1596). 13. When oxidised by KMnO_4 , the hydroxide PhHgOH is probably first formed, but on adding HCl this is changed to PhHgCl (Seidel, *J. pr.* [2] 29, 134; Otto, *J. pr.* [2] 29, 136).

Mercuric phenyl-chloride $\text{C}_6\text{H}_5\text{HgCl}$. **Mercuric chlorophenylide**. [250°]. Obtained by slowly passing chlorine over HgPh_2 , or into its solution in CS_2 . Prepared by heating HgPh_2 with HgCl_2 in alcoholic solution at 110° . Trimetric tables (from benzene). May be sublimed. Sl. sol. alcohol and benzene, insol. water.

Mercuric phenyl-bromide $\text{C}_6\text{H}_5\text{HgBr}$. [275°]. Resembles the preceding in preparation and properties. Br forms HgBr_2 and bromo-benzene. When heated with an alcoholic solution of K_2S the products are KBr , HgS , and HgPh_2 .

Mercuric phenyl-iodide $\text{C}_6\text{H}_5\text{HgI}$. [266°]. From HgPh_2 and I in alcohol. Satiny tables (from alcohol-benzene). Insol. water, nearly insol. cold alcohol, ether, and benzene, m. sol. hot benzene and chloroform, v. sol. CS_2 .

May be partially sublimed. Sodium-amalgam reduces it in alcoholic solution to HgPh_2 .

Mercuric phenyl-hydroxide $\text{C}_6\text{H}_5\text{HgOH}$. From PhHgCl by boiling with alcohol and moist Ag_2O . White trimetric prisms (from alcohol), sol. boiling water, alcohol, and benzene, sl. sol. cold water. Softens at 160° , but is not melted at 200° . The aqueous solution is alkaline in reaction. Expels NH_3 from its salts; ppts. alumina from alum, and absorbs CO_2 from the air.

Mercuric phenyl-cyanide PhHgCy . [204°]. From HgPh_2 and HgCy_2 in alcoholic solution at 128° . Long slender trimetric prisms; v. sl. sol. boiling water, m. sol. boiling alcohol and benzene. Conc. HClAq at 120° forms HgCl_2 , formic acid, benzene, and NH_3 . Alcoholic KOH forms mercury, benzene, and potassium cyanate. Iodine forms PhHgI and ICy . H_2S forms HgS , benzene, and HCy .

Mercuric phenyl-sulphocyanide PhHgSCy . [227°]. From HgPh_2 and Hg(SCy)_2 . Silky plates; sol. boiling alcohol.

Mercuric phenyl-nitrate PhHgNO_3 . [$c. 167^\circ$]. From PhHgCl and AgNO_3 in alcohol. Trimetric silky plates; v. sl. sol. boiling water. Conc. HClAq gives benzene and mercuric nitrate.

Mercuric phenyl-carbonate (PhHg), CO_3 . From PhHgCl and Ag_2CO_3 . Small white needles; sl. sol. boiling water, m. sol. boiling alcohol and benzene. Not decomposed on fusion.

Mercuric phenyl-formate PhHgOCHO . [171°]. From HgPh_2 and concentrated formic acid. Small tables.

Mercuric phenyl-acetate PhHgOAc . [149°]. Obtained by boiling HgPh_2 with excess of HOAc , ppq. with water, and crystallising from hot water. Radiate groups of prisms; sl. sol. cold, m. sol. hot, water; m. sol. alcohol and benzene. Decomposed by distillation yielding diphenyl, benzene, Ac_2O , HOAc , carbon, and mercury. Boiling aqueous HCl forms benzene, HgCl_2 , and HOAc . Other mineral acids act in like manner. Sodium-amalgam reduces it in alcoholic solution to benzene. Iodine, acting on its aqueous solution, forms HgI_2 , iodo-benzene and HOAc . H_2S forms HgS , benzene, and HOAc .

Mercuric phenyl-propionate $\text{PhHgOC}_2\text{H}_5$. [$c. 166^\circ$]. From HgPh_2 and boiling propionic acid. Crystals; sol. hot water, alcohol, and benzene.

Mercuric phenyl-myristate $\text{PhHgOC}_4\text{H}_9$. From HgPh_2 , myristic acid, and alcohol at 120° . Small scales; sol. boiling alcohol and benzene. Boiling HClAq splits it up into HgCl_2 , benzene, and myristic acid (Otto, *J. pr.* [2] 1, 179).

Mercuric tetra-methyl-di-amido-di-phenyl ($\text{NMe}_2\text{C}_6\text{H}_4$), Hg . [169°]. Formed by the action of sodium-amalgam in presence of EtOAc on *p*-bromo-di-methyl-aniline dissolved in xylene (Schenk a. Michaelis, *B.* 81, 1501). Colourless crystals, turning green in air. Crystallises from benzene with C_6H_6 (1 mol.). V. e. sol. chloroform, and benzene, v. sl. sol. alcohol and ether.

Mercuric di-o-tolyl $\text{Hg}(\text{C}_6\text{H}_4\text{Me})_2$. [107°]. From *o*-bromo-toluene sodium-amalgam, and

acetic ether (Ladenburg, *A.* 173, 162). Large trimetric tables (from benzene).

Mercuric o-tolyl-chloride

[3:1]C₇H₇Me.HgCl. *o*-Tolyl-mercuric chloride. [146°]. Formed by treating mercuric di-*o*-tolyl with HgCl₂ in ethereal solution (Michaelis & Genzken, *A.* 242, 180). Needles; v. sol. chloroform, m. sol. alcohol and benzene, sl. sol. ether and petroleum-ether. Sublimes with partial decomposition.

Mercuric m-tolyl-chloride

[8:1]C₇H₇Me.HgCl. [160°]. Obtained by boiling (C₆H₅Me)₂SbHgCl₂ with alcohol (M. & G.). Needles (from alcohol); v. sol. chloroform and benzene, m. sol. alcohol. H₂S passed into its alcoholic solution ppts. HgS.

Mercuric di-p-tolyl Hg(C₆H₄Me)₂ [238°]. Formed from *p*-bromo-toluene, sodium-amalgam, and EtOAc (Dreher & Otto, *A.* 154, 171; Ladenburg, *A.* 173, 163). Needles or tables; insol. water, sl. sol. cold alcohol, m. sol. hot benzene, CS₂, and CHCl₃. May be distilled. Boiling conc. HClAq gives toluene and HgCl₂.

Mercuric p-tolyl-chloride

C₆H₄Me.HgCl. [187°]. Small tables (Otto, *J. pr.* [2] 1, 185).

Mercuric p-tolyl-iodide C₆H₄Me.HgI. [220°]. From mercuric di-*p*-tolyl and iodine. Trimetric satiny tables; insol. water, sl. sol. boiling alcohol, m. sol. hot benzene. May be sublimed.

Mercuric p-tolyl-acetate

C₆H₄Me.HgOAc. [153°]. Small trimetric prisms; nearly insol. cold water, sl. sol. boiling water, m. sol. alcohol. Behaves like the corresponding phenyl compound.

Mercuric-di-p-xylyl (C₆H₄Me)₂Hg. [123°]. Prepared by the action of sodium-amalgam on bromo-*p*-xylene (Jacobsen, *B.* 14, 2112). Thick prisms; sol. CS₂, chloroform, and benzene, sl. sol. alcohol and ether.

Mercuric di-m-xylyl [1:3:4] (C₆H₄Me)₂Hg. [170°]. From bromo-*m*-xylene and 2 p.c. sodium-amalgam by heating at 145° for 12 hours (Weller, *B.* 20, 1718). Slender felted needles; sl. sol. ether, alcohol, and cold benzene; v. sol. hot benzene. Boiling HClAq gives HgCl₂ and *m*-xylene. PCl₅ forms C₆H₄Me₂POCl₂ (257°) and C₆H₄Me₂HgCl.

Mercuric di-n-propyl-di-phenyl Hg(C₆H₅Pr)₂ [110°]. From Br.C₆H₅Pr [1:4] and sodium-amalgam (R. Meyer, *J. pr.* [2] 34, 103). Long needles.

Mercuric di-cymyl Hg(C₆H₄Me)₂ [134°]. Formed by heating a mixture of bromo-cymene with xylene and sodium-amalgam with addition of a little acetic ether (Paternò & Colombo, *B.* 10, 1749). Long slender needles; m. sol. boiling alcohol, benzene, and xylene.

Mercuric di-pentamethyl-phenyl Hg(C₆Me)₂ [266°]. From bromo-pentamethyl-benzene, chloroformic ether, and sodium-amalgam (Jacobsen, *B.* 22, 1220). Prisms (from xylene); v. sl. sol. alcohol and ether, v. sol. hot xylene.

Mercuric di-naphthyl Hg(C₁₀H₇)₂ Mol. w. 454. [243°]. S.G. 1.93 (Schröder, *B.* 12, 564). Formed by boiling (β)-bromo-naphthalene with several times its volume of crude xylene, pasty sodium-amalgam, and a little acetic ether for 19 hours, and filtering while hot (Otto & Möries, *A.* 147, 164; *Z.* [2] 3, 877; 4, 162). Small minute, trimetric prisms (from benzene

or CS₂). Not affected by air or light. Insol. water, sl. sol. boiling alcohol, cold benzene or ether, m. sol. hot CS₂, chloroform, and benzene. Decomposed by heat. Conc. HIAq forms HgI₂ and naphthalene. HCl and HBr act in a similar way. Iodine forms HgI₂, C₁₀H₇IgI, and ultimately C₁₀H₇I. It does not react with HgCl₂.

Mercuric naphthyl-bromide

C₁₀H₇HgBr. [196°]. From Hg(C₁₀H₇)₂ and bromine. Formed also by heating Hg(C₁₀H₇)₂ with HgBr₂. Needles; insol. water, sol. hot alcohol.

Mercuric naphthyl-iodide C₁₀H₇HgI. [185°]. From mercuric di-naphthyl and iodine (1 mol.) in CS₂. Soft satiny needles or dendritic groups. Not altered by light; insol. water, sl. sol. hot alcohol and benzene. Sodium-amalgam converts it into mercuric di-naphthyl.

Mercuric naphthyl-acetate

C₁₀H₇HgOAc. [154°]. Formed, together with naphthalene, by heating mercuric di-naphthyl with excess of HOAc. Small needles (from alcohol); insol. water, v. sol. hot HOAc, alcohol, CS₂, benzene, and chloroform, m. sol. ether. Hot HClAq gives naphthalene and HOAc. Sodium-amalgam acting on its alcoholic solution forms naphthalene and HOAc. Water at 140° has no action.

Mercuric naphthyl-butyrate

C₁₀H₇.Hg.OC₄H₉. [200°]. Very slender needles; sol. hot water.

MESACONIC ACID C₃H₄O₄ t.e.

CH₃.C(CO₂H).CH.CO₂H. Mol. w. 130. [202°]. S. 2.7 at 18°; 118 at 100° (Pebal, *A.* 78, 130); 2.6 at 14°; 3.4 at 22° (Baup, *A.* 81, 97). S. (90 p.c. alcohol) 30.6 at 17°; 95.7 at 78° (P.); (88 p.c. alcohol) 38 at 22° (B.). *R_∞* 46.9 in a 3.69 p.c. aqueous solution (Kanonnikoff, *J. pr.* [2] 31, 349). *Heat of solution* -5493. *Heat of combustion* 27,334 (Gal & Werner, *Bl.* [2] 47, 159). H.C. 479,063 (Lougainine, *C. R.* 106, 1291).

Formation.—1. By boiling a dilute solution of citraconic acid for half an hour with one-sixth of its volume of nitric acid. Mesaconic acid is deposited on cooling (Gottlieb, *A.* 77, 268; Pebal, *A.* 78, 129; Baup, *A.* 81, 96).—2. By boiling citric acid with conc. HIAq or HBrAq (Kekulé, *A. Suppl.* 2, 94; Fittig, *A.* 188, 77, 80).—3. By heating a conc. aqueous solution of itaconic or citraconic acid at 180° to 200°, CO₂ and an empyreumatic oil being also formed (Swarts, *Bull. Acad. Royale Belgique*, [2] 36, No. 7).—4. From *citra-* and *mesa*-di-bromo-pyrotartaric acids by heating with KI and copper at 150° (Swarts, *Z.* 1868, 259).—5. The mono-anilide is heated with (3 mol. of) KOH and a little water for 1½ hours in the water-bath. The aniline separates out and is removed by means of ether, the acid being ppd. by means of SO₂H₂ (Anschütz, *A.* 254, 136).—6. 'Oxy-tetric acid,' which is formed from methyl-aceto-acetic acid by successive treatment with bromine and alcoholic potash (Demarcay, *A. Ch.* (5) 20, 473), is identical with mesaconic acid (Gorboff, *J. R.* 1887, 605; Cloës, *Bl.* [3] 3, 598, 602).

Preparation.—By evaporating a mixture of citraconic anhydride (10 pts.), water (22 pts.), and conc. HNO₃ (3 pts.), until red fumes begin to appear. The product is crystallised from water (Fittig, *A.* 188, 78).

Properties.—Slender needles (from water) or

prisms (from alcohol); al. sol. cold, v. sol. hot, water. V. sol. alcohol and ether. May be sublimed without decomposition. Its molecular weight, determined by Raoult's method, is identical with that of citraconic and of itaconic acid (Paternò, *B.* 21, 2157). Mesaconic acid is slightly coloured by FeCl_3 , and the solution when boiled yields a brown gelatinous pp. which re-dissolves on cooling. The addition of more FeCl_3 prevents its re-dissolving. Neutral solutions of mesaconates give a brown pp. with FeCl_3 , insoluble in excess of the reagent or when heated.

Reactions.—1. Conc. HIAq at 160° forms pyrotartaric acid.—2. Sodium amalgam also reduces it to pyrotartaric acid. The same reduction may be effected by zinc-dust (Böttinger, *B.* 9, 1821).—3. Bromine has no action in the cold (difference from citraconic acid) but above 60° it combines, forming mesa-di-bromo-pyrotartaric acid [170°] (Kekulé, *A. Suppl.* 2, 85).—4. Chlorine passed into water in which mesaconic acid is suspended forms a solution which when evaporated leaves chloro-citramalic acid $\text{C}_6\text{H}_7\text{ClO}_4$ (chloro-oxy-pyrotartaric acid). The same acid is formed, together with tri-chloro-acetone, by passing chlorine into an aqueous solution of sodium mesaconate.—5. Does not combine with HBr in the cold, but by prolonged heating with HBrAq at 100° or 140° it is converted into citra-bromo-pyrotartaric acid; an acid that is formed also by the union of HBr with citraconic acid in the cold.—6. When repeatedly heated with fuming HClAq at 160° it is converted into citra-chloro-pyrotartaric acid [130°], which is decomposed by boiling water into HCl and mesaconic acid (Swarts).—7. The electrolysis of potassium mesaconate yields, at the positive pole, CO_2 and allylene (Aarland, *J. pr.* [2] 6, 256; 7, 142).—8. AsCl_3 forms citraconic anhydride. Mesaconic anhydride has not been obtained (Petri, *B.* 14, 1636).—9. On evaporating a solution of the *aniline* salt water is not eliminated from the molecule (difference from citraconic acid).

Salts.— $\text{Me}_2\text{HA}''$. S. 12.5 at 15° . Very small prisms.— BaA'' 4aq: monoclinic crystals, more sol. water than barium citraconate and itaconate (Petri, *B.* 14, 1634).— BaHA'' 2aq: pearly hexagonal plates.— CaA'' aq. S. 6 at 20° . Very small needles, insol. alcohol.— PbA'' 1½aq: deposited in the cold as a crystalline pp., v. sl. sol. water.— PbA'' aq: deposited from a hot solution as an amorphous pp.— $\text{PbH}_2\text{A}''$ (dried at 100°). Small needles.— $(\text{HO.Pb})_2\text{A}''$: ppd. by adding lead subacetate to a solution of sodium mesaconate (Otto, *A.* 127, 182).— CuA'' 2aq.— AgA'' : crystalline pp., sl. sol. water.— ApHA'' : needles, m. sol. hot water.

Methyl ether $\text{Me}_2\text{A}''$ (205° i. V.). S. 8 at 15° . S.G. $\frac{1}{2}$ 1.1254; $\frac{3}{4}$ 1.1138. M.M. 1.154 at 24° . μ_D 1.4664 at 16° (Gladstone); 1.4570 at 17° (Knops, *A.* 248, 195); μ_H 1.4813 at 16° (Gladstone). From the acid, MeOH , and HCl (Perkin, *C. J.* 89, 556).

Ethyl ether (229° i. V.). S.G. $\frac{1}{2}$ 1.051; $\frac{3}{4}$ 1.039 (Perkin); $\frac{3}{4}$ 1.0468 (Knops, *A.* 248, 196). M.M. 1.168 at 25° . μ_D 1.4438; μ_H 1.4727 at 16° (Gladstone; cf. Knops). Formed by the action of alcohol and HCl on mesaconic and on citraconic acids.

Chloride $\text{C}_6\text{H}_4(\text{COCl})_2$ (80° at 17 mm.).

Prepared by the action of PCl_5 on mesaconic acid or citraconic anhydride (Petri, *B.* 14, 1634). Colourless liquid.

Amide $\text{C}_6\text{H}_5\text{O}_2(\text{NH}_2)_2$: [177°]; colourless flat crystals, sol. water.

Anilide $\text{C}_6\text{H}_5\text{O}_2(\text{NHPH})_2$: [186°]; flat white silky needles, sol. alcohol and ether, sl. sol. water. Heated to 268° it decomposes into aniline and citraconanil (the phenylimide of citraconic acid) (O. Strecker, *B.* 15, 1639).

Mono-anilide $\text{C}_6\text{H}_4(\text{CO}_2\text{H})(\text{CONHPH})$. [158°]. Formed by heating citraconic anhydride with aniline at 170° , rectifying *in vacuo* the resulting phenylimide (172° at 12 mm.), dissolving it in baryta-water, ppg. excess of barium by CO_2 and then adding HCl (Anschütz, *A.* 254, 183). Identical with the product which separates from an aqueous solution of acid aniline citraconate on standing. White powder. Converted by heating in a sealed tube with KOH into mesaconic acid.

Constitution.—Mesaconic acid stands to citraconic acid in the same relation that fumaric stands to maleic acid. This is shown by their behaviour towards Br , HBr , and aniline, and by the physical constants of their ethers. Hence mesaconic acid is methyl-fumaric acid, while citraconic acid is methyl-maleic acid. The constitution of mesaconic acid will therefore be known as soon as that of fumaric acid has been satisfactorily determined (v. Maleic acid).

MESA-DI-BROMO-PYROTARTARIC ACID o.
DI-BROMO-PYROTARTARIC ACID.

TRIMESIC ACID $\text{C}_6\text{H}_3\text{O}_7$, i.e.
 $\text{C}_6\text{H}_3(\text{CO}_2\text{H})_3$, [1:3:5]. *Benzene-s-tri-carboxylic acid*. Mol. w. 210. [α 325°]. H.C.v. 768,500. H.C.p. 767,600. H.F. 285,400 (Stohmann, Kleber a. Langbein, *J. pr.* [2] 40, 140).

Formation.—1. By the oxidation of mesitylene or mesitylenic acid by chromic acid mixture (Fittig, *A.* 141, 153).—2. By the oxidation of uvitic acid (Baeyer, *Z.* 1868, 119; Fittig, *A.* 147, 301), and of s-tri-ethyl-benzene (Jacobsen, *B.* 7, 1435; Friedel a. Balsohn, *Bl.* [2] 34, 636) by chromic acid mixture.—3. One of the products obtained by heating hydromellitic or isohydromellitic acid with conc. H_2SO_4 (Baeyer, *A. Suppl.* 7, 40, 48).—4. By heating mellitic acid with glycerin (Baeyer, *A.* 166, 340).—5. In very small quantity by fusing the corresponding bromo-benzene sulphonic acid with sodium formate (Böttinger, *B.* 7, 1781).—6. By fusing benzene s-trisulphonic acid with KCO_2 and saponifying the resulting nitrile with KOH (Jackson a. Wing, *Am.* 9, 347).—7. From di-sodium salicylate $\text{C}_6\text{H}_4(\text{ONa})_2\text{CO}_2\text{Na}$ by heating in a current of carbonic acid, converting the resulting $\text{C}_6\text{H}_4(\text{OH})(\text{CO}_2\text{H})$ into $\text{C}_6\text{H}_3\text{Cl}(\text{CO}_2\text{H})_2$, and reducing with zinc and dilute acids.—8. By the polymerisation of propiolic acid, which takes place to some extent when it is exposed for some weeks to sunlight, air being excluded (Baeyer, *B.* 19, 2185).—9. Trimesic ether is formed by the action of sodium upon a mixture of ethyl formate and ethyl acetate; formyl-acetic ether $\text{HCO.CH}_2\text{CO}_2\text{Et}$ is probably first formed and subsequently condensed (Pittti, *B.* 20, 537). When mixtures of methyl formate and ethyl acetate, or of ethyl formate with methyl acetate

are used a mixture of ethyl and methyl trim-sates is obtained.

Properties.—Colourless prisms (from water): partially sublimes before melting. M. sol. cold water and ether, v. sol. hot water, v. e. sol. alcohol. When distilled with lime it yields benzene.

Salts.— $\text{NaH}_2\text{A}''$: plates, sl. sol. cold water. — $\text{Na}_2\text{A}''$. — $\text{KH}_2\text{A}''$: needles, sl. sol. cold water. — $\text{Ca}_2\text{A}''$, aq: nodules. — $\text{Ba}_2\text{A}''$, aq (dried at 150°): needles, almost insol. cold, v. sl. sol. boiling water (difference from mesitylenic acid). — $\text{RaH}_2\text{A}''$, 4aq: slender hair-like needles, sl. sol. cold water. — $\text{Zn}_2\text{A}''$, 2aq: glittering prisms, almost insol. cold water. — $\text{Cu}_2\text{A}''$, aq (dried over H_2SO_4). Pale-blue pp. — $\text{Ag}_2\text{A}''$.

Methyl ether $\text{Me}_2\text{A}''$. [143°]. Small silky needles. H.F. 249,600 (Stohmann, J. pr. [2] 40, 353).

Ethyl ether EtA'' . [133°]. Prepared by adding a mixture of formic and acetic ethers by drops to twice the amount of ether, in which sodium is placed. On adding dilute H_2SO_4 , an oil is obtained, which gives a blue-violet colour with FeCl_3 , and on standing in a desiccator deposits crystals of trimetic ether (Wislicenus, B. 20, 2930). Long glistening prisms. A mixture of this ether and the preceding in equal proportions melts at 105° to 110° .

Sulpho-trimesic acid. *Amide.* $\text{C}_6\text{H}_3(\text{SO}_2\text{NH}_2)(\text{CO}_2\text{H})_3$. Formed by oxidising the amide of either of the sulpho-mesitylenic acids with KMnO_4 (Jacobsen, A. 206, 203). — $\text{KH}_2\text{A}''$, 2aq: crystalline mass, m. sol. water. Conc. HClAq at 210° gives trimesic acid, NH_3 , and H_2SO_4 . Potash-fusion gives oxy-trimesic acid.

MESICERIN v. TRI-OXY-MESITYLENE.

MESIDIC ACID v. UVITIC ACID.

MESIDINE $\text{C}_6\text{H}_3\text{N}$ i.e.

$\text{C}_6\text{H}_3(\text{CH}_3)_3\text{NH}_2$ [1:3:5:6]. *Amido-mesitylene.* (229°) (Ladenburg, A. 179, 172). S.G. .963.

Formation.—1. By boiling nitro-mesitylene with tin and HClAq (Kittig a. Storer, A. 147, 1). —2. From di-methyl-aniline methylo-iodide, by heating in a sealed tube at 335° (Hofmann, B. 5, 715; 8, 61). —3. By heating *u-m*-xylydine hydrochloride or *c-m*-xylydine hydrochloride with methyl alcohol at 300° (Eisenberg, B. 15, 1012; Nölting a. Forel, B. 18, 2681). —4. By heating aniline hydrochloride with MeOH at 800° (Limpach, B. 21, 640).

Properties.—Liquid. Gives *m*-xyloquinone on oxidation. When heated with MeOH and HCl for forty-eight hours at 230° it yields di-methyl-mesidine (c. 215°). ClCO_2Et yields $\text{C}_6\text{H}_3\text{Me}_3\text{NH}_2\text{CO}_2\text{Et}$ [62°] (Eisenberg, B. 15, 1016).

Salts.— B^+HCl : feathery crystals or prisms, v. sol. water and alcohol. — $\text{B}^+\text{H}_2\text{PbCl}_2$. — $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$: plates, sl. sol. cold water.

Acetyl derivative $\text{C}_6\text{H}_3(\text{CH}_3)_3\text{NHAc}$. [217°]. Prisms (from alcohol). May be sublimed.

Benzoyl derivative $\text{C}_6\text{H}_3(\text{CH}_3)_3\text{NHBz}$. [204°]. Needles (Schaak, B. 10, 1711).

MESIDINE SULPHONIC ACID $\text{C}_6\text{H}_3\text{NSO}_3\text{H}$ i.e. $\text{C}_6\text{H}(\text{NH}_2)(\text{CH}_3)_2\text{SO}_3\text{H}$ [6:1:3:5:4]. *Amido-mesitylene sulphonic acid.* From nitro-mesitylene sulphonic acid by reduction with NH_4 and H_2S (Rose, A. 164, 70). Slender prisms or needles (containing aq) (from water), v. sol. hot

alcohol, sl. sol. cold water. Does not combine with HCl or H_2SO_4 . — BaA' : nodules, m. sol. cold water. — MgA' , 8aq. — ZnA' , 6aq. — PbA' , aq: crystalline; v. sol. cold water. — AgA' .

MESITENE LACTONE v. vol. i. p. 21 and BROMO-MESITENE LACTONE.

TRI-MESITIC ACID v. PYRIDINE TRI-CARB-XYLIC ACID.

FESITOL $\text{C}_6\text{H}_3\text{O}$ i.e.

$\text{C}_6\text{H}_3(\text{OH})_3(\text{OH})$ [1:3:5:6]. *Oxy-mesitylene*. [69°]. (219.5° i. V.). Obtained from mesidine by the diazo reaction, and by fusing mesitylene sulphonic acid with potash (Biedermann a. Ledoux, B. 8, 57, 250; Jacobsen, A. 195, 268). Crystals, v. e. sol. alcohol and ether. Volatile with steam. Insol. NH_4Aq and aqueous Na_2CO_3 ; v. sol. NaOHAq . Not coloured by FeCl_3 . Forms a sulphonic acid, which has an easily soluble barium salt, coloured deeply by FeCl_3 . This sulphonic acid yields oxy-mesitylenic acid by potash-fusion.

Methyl derivative $\text{C}_6\text{H}_3(\text{CH}_3)_3(\text{OCH}_3)_2$. (c. 202°). Liquid. Bromine gives a bromo-derivative [80°]. V. AMIDO- and BROMO-MESITOL.

MESITONIC ACID $\text{C}_6\text{H}_3\text{O}_2$ or $(\text{CH}_3)_2\text{C}(\text{CO}_2\text{H})_2\text{CH}_2\text{CO}_2\text{H}$ (?). *Di- α -methyl- β -acetyl-propionic acid*. [74°] (Anschütz). [90°] (P.). (138° at 15 mm.). (230° – 240°) at 760 mm. Prepared, together with an acid ($\text{C}_6\text{H}_3\text{NO}_2$) and phoronic nitrile ($\text{C}_6\text{H}_3\text{N}_2\text{O}_2$), by boiling the product of the action of gaseous HCl on acetone, with alcoholic KCN . In this reaction the substance first formed is probably the chloride $(\text{CH}_3)_2\text{CClCH}_2\text{CO}_2\text{CH}_3$, which by KCN would give the nitrile of mesitonic acid (Pinner, B. 14, 1071). Plates or prisms. Sol. water, alcohol, ether, and benzene, sl. sol. petroleum-ether. Its salts are v. e. sol. water. On distillation it splits off water, forming mesito-lactone $\text{C}_6\text{H}_3\text{O}$. Yields di-methyl-malonic acid on oxidation with HNO_3 (Anschütz, A. 247, 103). On reduction it yields the lactone of γ -oxy-di- α -methyl-valeric acid $(\text{CH}_3)_2\text{C}_2\text{CH}_2\text{CHMeO.CO}$ [52°].

Ethyl ether $\text{C}_6\text{H}_3(\text{OH})_2\text{OEt}$. (210°). Colourless liquid.

Acetyl derivative of the ethyl ether $\text{C}_6\text{H}_3(\text{OAc})_2\text{OEt}$. (206°). Liquid (Pinner, B. 15, 578).

Phenyl hydrazide

$\text{PhHN}:\text{CMe}_2\text{CH}_2\text{CMe}_2\text{CO}_2\text{H}$. [121.5°]. Small prisms (from benzene or dilute alcohol). On boiling with a few drops of HClAq it yields crystalline $\text{C}_6\text{H}_3\text{N}_2\text{O}$ [84°].

Compound with Hydrogen Cyanide

Mesitylic acid. [174°]. Prepared, together with mesitonic acid and phoronic nitrile, by boiling the product of the action of HCl on acetone with alcoholic KCN . In this reaction it is probably formed by the addition of HCN to mesitonic acid or its nitrile (Simpson, A. 148, 851; Pinner, B. 14, 1071; 15, 580). Distils undecomposed at a high temperature. Large flat prisms (containing aq). Very stable body. Forms easily soluble salts. By heating with HCl to 140° CO_2 and NH_3 are split off. Heated with concentrated H_2SO_4 to 150° it is converted

into mesitonic acid. On oxidation with KMnO_4 in acid solution it gives di-methyl-succinimide and di-methyl-malonamic acid [107°].

Ethyl ether Δ/Et . [90°]. Colourless prisms. Sol. alcohol and in acid, sl. sol. water.

Amide $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$. [222°]. Colourless crystals. Sol. water and alcohol.

Mesito-lactone $\text{C}_6\text{H}_4\text{O}_2$ i.e.
 $(\text{CH}_3)_2\text{C}(\text{OH})\text{C}(\text{OH})_2$
 $\text{CO}-\text{O}$
Lactone of Oxy-heptenoic

acid. [24°]. (167°). Prepared by distillation of mesitonic acid (Pinner, *B.* 15, 579). Large colourless prisms, sl. sol. water. Neutral body. By boiling with KOH it is reconverted into mesitonic acid. It combines with bromine.

MESITYL. This name was given by Kane (*P.* 44, 476) to a radicle C_6H_3 , of which he supposed acetone to be the hydroxide and **MESITYL OXIDE** (q. v.) the oxide. More recently it has been employed to denote both *s*-di-methyl-benzyl and *s*-tri-methyl-phenyl.

MESITYL ALCOHOL v. ω -OXY-MESITYLENE.

MESITYL BROMIDE v. BROMO-MESITYLENE.

MESITYLENE C_6H_3 i.e. $\text{C}_6\text{H}_4\text{Me}$, [1:3:5].
s-Tri-methyl-benzene. Mol. w. 120. (164.5°) (Schiff, *A.* 220, 94). S.G. $\frac{98}{7}$ 8694 (S.); $\frac{92}{7}$ 8558 (Brühl, *A.* 200, 190). C.E. (9.8° to 164.5°) 001159 (S.). V.D. 4.4 (obs. and calc.). S.V. 162.4 (Schiff); 162.2 (Ramsay). $\mu_p = 1.5015$. $R_\infty = 65.75$ (B.). H.C. = 1,251,660 [C_6H_4 = 94,000; H_2O = 69,000] (Stohmann, *J. pr.* [2] 35, 41); 1,282,310 (Thomsen, *Th.* 4, 63). H.F.p. = 490. H.F.v. = -2410 (*Th.*).

Occurs in coal-tar oil (Fittig a. Wackenroder, *A.* 151, 292; Jacobson, *A.* 184, 179; *B.* 9, 256; 10, 855). It is also one of the products of the manufacture of oil-gas (Armstrong, *C. J.* 49, 74). Occurs in all kinds of petroleum (American, Russian, &c.) (Engler, *B.* 18, 2234).

Formation.—1. By distilling acetone with H_2SO_4 (Kane, *P.* 44, 474; Hofmann, *C. J.* 2, 104; Cahours, *C. R.* 24, 255; *C. J.* 3, 17).—2. By the action of H_2SO_4 on allylene (Fittig a. Schrode, *B.* 8, 17).—3. By treating toluene with MeCl in presence of AlCl_3 , ψ -cumene being also formed (Friedel a. Crafts, *A. Ch.* [6] 1, 461; Ador a. Rilliet, *B.* 12, 829).

Preparation.—1. By mixing 180 g. acetone with 300 g. sulphuric acid, allowing to stand for an hour, then distilling gently, using a current of steam at the end of the operation. The yield is 40 g. (Varenne, *Bl.* [2] 40, 266).—2. H_2SO_4 (2 vols.) diluted with water (1 vol.) is slowly added to a mixture of crude acetone (2 vols.) and sand. After 24 hours the mixture is distilled. The oil thus obtained is washed with aqueous NaOH and rectified (Fittig a. Brückner, *A.* 147, 42).—3. The fraction of coal-tar oil boiling between 160° and 168° is agitated with H_2SO_4 and the resulting sulphonic acids converted first into Ba salts and then into Na salts. The Na salts are then treated with PCl_5 and the resulting chlorides converted into amides by NH_4Aq . On crystallising from alcohol, the ψ -cumene sulphonamide separates first, and then mesitylene sulphonamide. The mesitylene sulphonamide is then heated with conc. HClAq at 160° (Jacobson).—4. The sulphonic acids of ψ -cumene and of mesitylene may also be separated by heating

with HClAq at 100° for 1 hour, when mesitylene sulphonic acid is decomposed into mesitylene and H_2SO_4 , while ψ -cumene sulphonic acid is not affected (Armstrong, *B.* 11, 1697).—5. When steam is passed through a heated solution of mesitylene sulphonic acid in dilute H_2SO_4 , hydrolysis into mesitylene and H_2SO_4 begins as soon as the temperature reaches 100° (Armstrong a. Miller, *C. J.* 45, 148).

Properties.—Light oil.

Reactions.—1. Br and Cl form crystalline substitution-products.—2. Fuming HNO_3 mixed with fuming H_2SO_4 forms tri-nitro-mesitylene. 3. Boiling dilute HNO_3 oxidises it to mesitylenic acid and uvitic acid (Fittig, *A.* 141, 142).—4. $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 yield acetic acid (Fittig). 5. KMnO_4 oxidises it to uvitic and trimesic acids (Jacobsen, *A.* 184, 191).—6. When heated with AlCl_3 in a current of HCl it yields MeCl and *m*-xylene, toluene, and benzene (Jacobsen, *B.* 18, 342).—7. MeI in presence of AlCl_3 yields (1, 2, 4, 5)-tetra-methyl-benzene (durene) (Barbier a. Roux, *Bl.* [3] 2, 4).—8. *Benzyl chloride* and AlCl_3 at 100° form benzyl-mesitylene (q. v.). 9. *Benzoyl chloride* in presence of aluminium chloride forms phenyl tri-methyl-phenyl ketone $\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_3\text{Me}_3$ [36°] and the compounds $(\text{C}_6\text{H}_5\text{CO})_2\text{C}_6\text{H}_3\text{Me}_3$ [117°] and $(\text{C}_6\text{H}_5\text{CO})_3\text{C}_6\text{H}_3$ [215°] (Louise, *A. Ch.* [6] 6, 200).—10. PCl_5 at 180° gives a small quantity of $\text{C}_6\text{H}_3(\text{CH}_2\text{Cl})_3$ (Colson a. Gautier, *Bl.* [2] 45, 6).—11. Mesitylene is very readily attacked by *halogens*. In the *dark*, mono- di- or tri- (*eso*)-bromo-mesitylene ($\text{C}_6\text{H}_3\text{Me}_3\text{Br}$, $\text{C}_6\text{H}_3\text{HMe}_2\text{Br}$, and $\text{C}_6\text{H}_3\text{Me}_2\text{Br}_2$) are formed according as 1, 2, or 3 mols. of bromine are employed. Chlorine acts similarly. The presence of iodine, though not required, does not effect the reaction. At the *boiling-point* the bromine, as usual, enters the side-chains, 1 mol. Br forming ω -bromo-mesitylene (mesityl bromide) $\text{C}_6(\text{CH}_3)_2\text{CH}_2\text{Br}$ melting at [38°]. Direct *sunshine*, which usually acts like heat, in the case of mesitylene, owing to the great tendency to displacement of the nuclear hydrogen, produces a different result; (*eso*)-mono-bromo-mesitylene is first produced but is partly attacked by the rest of the bromine forming the liquid *p*- ω -di-bromo-mesitylene (*p*-bromo-mesityl-bromide) $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Br}(\text{CH}_2\text{Br})$ [5:3:4:1]. If *eso*-bromo-mesitylene be exposed to further bromination in sunshine, the reaction proceeds normally, producing *p*- ω -di-bromo-mesitylene (as above), and, on further action, *p*- ω -tri-bromo-mesitylene $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Br}(\text{CH}_2\text{Br})_2$ [5:4:3:1] melting at [122°] (Schramm, *B.* 19, 212).—12. When a 10 f.c. solution of mesitylene in CS_2 is mixed with a similar solution of chromyl chloride CrO_2Cl_2 a pp. $(\text{O}_6\text{H}_3\text{Me}_3)(\text{CrO}_2\text{Cl}_2)$ is obtained which when decomposed by water yields di-methyl-benzoic aldehyde (221°), which is oxidised by air to mesitylenic acid (Etard, *C. R.* 97, 909).—13. The diacetyl derivative of *ortho-formic aldehyde* (1 pt.) mixed with mesitylene (1 pt.) and HOAc (10 pts.) condenses on adding a mixture of HOAc (10 pts.) with an equal volume of H_2SO_4 ; and after 24 hours crystals of $(\text{O}_6\text{H}_3\text{Me}_3)_2\text{CH}_2$ [130°] separate. The formation of this body may be used as a test for mesitylene, a mixture of methyl alcohol and CrO_3 in HOAc being used instead of $\text{CH}_3(\text{OAc})$, (Baeyer, *B.* 5, 1094; 6, 220).

Constitution.—The explanation of the for.

mation of mesitylene by condensation of acetone was first given by Baeyer (*A.* 140, 306). That the three methyls are symmetrically situated in the benzene nucleus would appear from the existence of only one mono-derivative derived by displacing an atom of hydrogen in the nucleus, *e.g.* there is only one nitro-mesitylene. A systematic proof of the symmetry of mesitylene has been given by Ladenburg (*A.* 179, 163). He prepares in succession $C_6Me_3(NO_2)(NO_2)H$, $C_6Me_3(NO_2)(NH_2)H$, $C_6Me_3(NO_2)(NH_2)(NO_2)$, and $C_6Me_3(NO_2)H(NO_2)$. Since the last di-nitro-mesitylene is identical with the first, the second and third hydrogen atoms are similarly situated in the nucleus. Again, from the above nitro-mesidine $C_6Me_3(NO_2)(NH_2)H$ Ladenburg obtained $C_6Me_3(NO_2)HH$ and, by reducing this, mesidine $C_6Me_3(NH_2)HH$. Nitro-mesidine, obtained by nitrating $C_6Me_3(NH_2)HH$, must be either $C_6Me_3(NH_2)(NO_2)H$ or $C_6Me_3(NH_2)H(NO_2)$. But since it has been shown that the second and third atoms of hydrogen are similarly situated, these two formulae are identical. And since the nitro-mesidine* is found to be identical with the $C_6Me_3(NO_2)(NH_2)H$ prepared from the di-nitro-mesitylene $C_6Me_3(NO_2)(NO_2)H$, it follows that the first and second atoms of hydrogen are similarly situated. Hence all three atoms of hydrogen are similarly situated, and the formula will be $C_6Me_3H_3$ [1:3:5].

Mesitylene hexahydride C_6H_8 , *i.e.* $C_6Me_3H_2$, (*c.* 137°). Obtained by heating mesitylene with PH_3 at 280° (Baeyer, *Z.* [2] 5, 320; *A.* 155, 273). Oil, smelling like petroleum. Converted by prolonged heating with fuming HNO_3 into tri-nitro-mesitylene.

MESITYLENE GLYCOL *v.* DI-OXY-MESITYLENE.

MESITYLENE PHTHALOYLIC ACID *v.* PHENYL TRI-METHYL-PHENYL KETONE CARBOXYLIC ACID.

MESITYLENE SULPHINIC ACID $C_6H_3Me_3SO_2H$ [1:3:5:6]. [99°]. Formed by adding a mixture of sodium-amalgam and $C_6H_3Me_3SO_2Cl$ to a dry mixture of benzene and toluene, and decomposing the resulting pulpy mass with HCl (Holtmeyer, *Z.* 1867, 686). Fan-shaped groups of needles.— BaA' , $aq.$ — AgA' .

MESITYLENE SULPHONIC ACID $C_6H_3Me_3SO_3H$, (*c.* 77°). Formed by dissolving mesitylene in warm H_2SO_4 (Hofmann, *C. J.* 2, 113; Jacobsen, *A.* 146, 85; 184, 185; Beilstein a. Kögler, *A.* 137, 817; Fittig, *J.* 1866, 610; *Z.* [2] 4, 593). Trimetric six-sided tables (containing 2aq) (Rose, *Z.* [2] 6, 841; *A.* 184, 58; Bodewig, *J.* 1879, 737). Decomposed by distillation with dilute H_2SO_4 into mesitylene and H_2SO_4 , the hydrolysis beginning at 100° (Armstrong a. Miller, *C. J.* 45, 149). Gives mesitol on potash-fusion (Jacobsen, *A.* 195, 265).

Salts.— KA' *aq.* Roundish groups of silky

laminae. *S.* 14 at 19°.— NH_4A' *aq.* [350°]. Plates, *v.* sol. water and alcohol.— CaA' , 5aq: efflorescent crystals.— BaA' , 9aq. *S.* 6.6 at 18°; 5.5 at 11.5°.— SrA' , 7aq.— MgA' , 6aq.— CoA' , 6aq: flesh-coloured laminae, *v.* sol. water and alcohol.— CuA' , 4aq. Pale-green laminae. *S.* 6 at 10°.— PbA' , 9aq. Pearly plates. *S.* 15 at 20°.

Chloride $C_6H_3Me_3SO_2Cl$. [57°]. Wedge-shaped tables (from ether), insol. water, *v.* sol. alcohol and ether (Holtmeyer, *Z.* 1867, 686).

Amide $C_6H_3Me_3SO_2NH_2$. [142°]. *S.* .083 at 0°; .54 at 100°. *S.* (83 p.c. alcohol) 5.5 at 0°; 114 at 78°. Fibrous mass (from alcohol) or hair-like needles (from ether). May be oxidised to $C_6H_3Me_3(CO_2H)_2SO_2NH_2$ and an acid $C_6H_3Me_3(CO_2H)_2SO_2NH_2$, and the anhydride of an isomeric acid $C_6H_3Me_3\langle\begin{smallmatrix} SO \\ CO \end{smallmatrix}\rangle NH$ (Hall a.

Remsen, *Am.* 2, 130; Emerson, *Am.* 8, 268).

Imide $(C_6H_3Me_3SO_2)_2NH$. [124°]. Formed by heating the amide with a little HCl in a sealed tube. Long needles, *m.* sol. hot water, sol. $NaOH$ *aq.*, and reppd. by HCl .

Mesitylene disulphonic acid $C_6H_3Me_3(SO_3H)_2$. Formed by dissolving mesitylene (1 pt.) in fuming H_2SO_4 (10 pts.), and adding P_2O_5 (3 pts.), the temperature being kept low during the operation (Barth a. Herzig, *M.* 1, 807). Deliquescent needles. Gives oxy-mesitylenic acid on potash-fusion.— K_2A'' 2aq.— Na_2A'' 1½aq: needles.— BaA'' 8aq: needles.— CuA'' (dried over H_2SO_4): greenish-white needles.

References.—BROMO-MESITYLENE SULPHONIC ACID.

MESITYLENIC ACID $C_6H_3O_2$, *i.e.*

$C_6H_3Me_3COOH$. *Di-methyl-benzoic acid*. *Mol.* w. 150. [166°]. *H.C.v.* 1,084,300. *H.C.p.* 1,085,200. *H.F.* 105,800 (Stohmann, Kleber, a. Langbein, *J. pr.* [2] 40, 135). Colourless plates.

Formation.—1. By boiling mesitylene with dilute HNO_3 (1 vol. of *S.G.* 1.4 and 2 vols. water) for 18 hours. The product is distilled with steam, boiled with a little tin and HCl *aq.* to remove a nitro-compound, and crystallised from alcohol (Fittig, *A.* 141, 144; Fittig a. Brückner, *Z.* [2] 4, 493; *A.* 147, 45).—2. By boiling *s*-dimethyl-ethyl-benzene with nitric acid (*S.G.* 1.1) (Jacobsen, *B.* 7, 1430; Wroblewsky, *B.* 9, 495). 3. By passing CO over a mixture of $NaOEt$ and $NaOAc$ at 205°; or by heating such a mixture with zinc-dust (Gauthier a. Fröhlich, *A.* 202, 310).

Properties.—Monoclinic crystals (from alcohol); *v.* sol. water, *v.* sol. alcohol. Sublimes below its melting-point. Distillation with lime yields *m*-xylene. Chromic acid mixture oxidises it to trimesic acid.

Salts.— NaA' (dried at 180°). *V.* sol. water and alcohol.— CaA' , ½aq. Not more soluble in hot than cold water.— BaA' : silky prisms.— MgA' , 5aq: groups of monoclinic prisms.— ZnA' (dried at 130°): laminae or needles, sol. water.— MnA' — NiA' (dried at 130°).— AgA' . Minute needles, sol. hot water.— AgA' *aq.* (Hall a. Remsen, *Am.* 2, 130).

Ethyl ether EtA' . (241°). Heavy oil; solidifies below 0°.

Amide $C_6H_3Me_3CONH_2$. [133°]. Needles; *v.* sol. cold water.

References.—AMIDO-, BROMO-, and CHLORO-MESITYLENIC ACID.

MESITYLENIC GLYCOL v. DI-OXY-MESITYL-ENE.

MESITYLENIC GLYCERIN v. TRI-OXY-MESITYLENE.

MESITYLIC ACID v. compound of MESITRONIC ACID with HCl.

MESITYL MERCAPTAN v. TRI-METHYL-PHENYL MERCAPTAN.

MESITYL OXIDE C_6H_4O i.e.

$(CH_3)_2C:CH.CO.CH_3$. *Methyl isobutenyl ketone. Isopropylidene-acetone.* (132°) at 751 mm. S.G. 0.8578. μ_D 1.4440. V.D. 8.67 (calc. 8.39). R_D 49.7 (Kanonnikoff, J. pr. [2] 31, 352).

Formation.—1. One of the products of the action of H_2SO_4 on acetone (Kane, P. 44, 476). 2. Together with phorone by leaving acetone for several weeks in contact with quicklime (Fittig, A. 110, 82).—3. One of the products of the action of $ZnEt_2$ or $ZnMe_2$ on acetone (Pawlow, B. 9, 1811; A. 188, 130).—4. In small quantity, together with other bases, by distilling diacetoneamine (Heintz, A. 174, 133; 181, 70; B. 8, 89).—5. By boiling with lime the lactonic products of condensation of aceto-acetic ether (Hantsch, A. 222, 21).—6. By boiling acetyl chloride with acetone (Beilstein a. Wiegand, B. [2] 88, 167).—7. Among the products of the distillation of glycerin with BaO (Destrem, A. Ch. [5] 28, 5).

Preparation.—Acetone is saturated with HCl and then left to itself for a fortnight. The product is mixed with water, and the heavy oil, containing hydrochlorides of mesityl oxide and phorone, decomposed by alcoholic or conc. aqueous KOH, and distilled with steam. The product is fractionally distilled (Baeyer, A. 140, 297).

Properties.—Oil, smelling like peppermint; insol. water, miscible with alcohol and ether.

Reactions.—1. Boiling dilute sulphuric acid forms acetone. Conc. H_2SO_4 gives mesitylene (Claisen, B. 7, 1168).—2. Boiling dilute nitric acid yields acetic and oxalic acids.—3. $KMnO_4$ oxidises it to acetic and oxy-isobutyric acid (Pinner, B. 15, 581).—4. Slowly combines with $NaHSO_4$ forming $NaC_6H_3SO_4$, the sodium salt of methyl isobutyl ketone sulphonic acid $CH_3.CO.CH_2.OMe.SO_3H$, which is decomposed by conc. $NaOH$ regenerating mesityl oxide (Pinner, B. 16, 1727).—5. Bromine acts violently. But when it is added to a solution of mesityl oxide in CS_2 , oily $C_6H_3Br_2O$ is formed. This can be distilled with steam, but in the dry state soon gives off HBr.—6. A solution in dilute alcohol is strongly attacked by sodium-amalgam and water then ppts. a heavy oil $C_{12}H_{20}O$ 'mesitic ether' or 'mesitic camphor' (c. 215°) smelling like camphor. A small quantity of a solid [110°–120°] is also formed (Claisen, A. 180, 7).—7. PCl_5 forms 'mesityl chloride' $C_6H_3Cl_2$, which separates on adding water as a heavy oil, smelling like oil of turpentine. It resinifies on exposure to air, and is decomposed by distillation over KOH, baryta, or lime into HCl and C_6H_3Cl , a liquid (180°) smelling like turpentine. 8. Ammonia forms diacetoneamine C_6H_3NO .—9. Hydriodic acid forms a heavy oil C_6H_3IO decomposed by alcoholic KOH into HI and mesitylene (Pawlow, A. 188, 189).—10. HCl passed into a mixture of mesitylene and benzoic aldehyde forms $C_6H_3.CO.CH:CHPh$ (Claisen a.

Claparède, B. 14, 349).—11. With acetamide and $ZnCl_2$ it forms oxy-tri-methyl-pyridine dihydride (Canzoneri a. Spica, G. 14, 849; B. 19, 818; cf. Engler a. Riehm, B. 19, 40).—12. With amyl nitrite and alcoholic NaOEt it forms the nitroso-derivative $OMe_2:CH.CO.CH:NOH$, crystallising in colourless prisms [102°] (Claisen a. Manasse, B. 22, 529).

Oxim C_6H_3NO i.e.

$(CH_3)_2C:CH.C(N.OH).CH_3$. (c. 185°). Formed by the action of hydroxylamine on mesityl oxide (Nägeli, B. 16, 495). Oil. Sol. alcohol, ether, benzene, CS_2 , ligroin, alkalis and acids. On warming with acids it is resolved into its constituents.

MESOCAMPHORIC ACID v. CAMPHORIC ACID.

MESORCIN v. TRI-METHYL-RESORCIN.

MESOTARTARIC ACID v. TARTARIC ACID.

MESOXALIC ACID $C_4H_2O_4$ aq i.e.

$CO_2H.CO.CO_2H$ + aq or $CO_2H.C(=O)_2.CO_2H$ (Petrieff, B. 11, 414). Mol. w. 136. [115°] (Deichsel); [108°] (Böttinger, A. 203, 140); [120°] (Fischer).

Formation.—1. Together with urea, by boiling alloxan or alloxanic acid with baryta. The resulting Ba salt is recrystallised and decomposed by H_2SO_4 (Liebig a. Wöhler, A. 26, 298; Svanberg, B. J. 27, 165; Deichsel, B. B. 1864, 587).—2. By treating amido-malonic acid with iodine and water (Baeyer, A. 131, 298).—3. By boiling di-bromo-malonamide $CB_2(CO.NH_2)_2$ with precipitated Ag_2O (Freund, B. 17, 782).—4. By boiling di-bromo-malonic acid with baryta-water (Petrieff, J. R. 10, 72).—5. By heating caftaric acid with concentrated aqueous lead subacetate (E. Fischer, A. 215, 283).

Properties.—Very deliquescent prisms, melting without loss of aq. M. sol. alcohol and ether, v. s. sol. water. Its concentrated aqueous solution decomposes above 80° into CO_2 , glycolic, oxalic, and glyoxylic acid (Böttinger, A. 203, 188). With acetates of Ba and Pb it gives flocculent pps. gradually becoming crystalline. In neutral solutions $CaCl_2$ and $BaCl_2$ give pps. It reduces hot ammoniacal $AgNO_3$.

Reactions.—1. H_2S passed into an aqueous solution to which silver oxide has been added forms thio-glycollic acid $CH_2(SH).CO_2H$ and thio-di-glycollic acid (sulphido-diacetic acid) $S(CH_2.CO_2H)_2$ (Böttinger).—2. Sodium amalgam acting on its dilute aqueous solution forms tartaric acid $CO_2H.CH(OH).CO_2H$.—3. Silver mesoxalate boiled with water yields CO_2 , oxalic acid, and silver.—4. Urea at 100° gives allantoin $C_4H_6N_4O_3$.—5. Hydroxylamine yields the oxim which is identical with nitroso-malonic acid.

Salts.— $[A'' = C_2O_3]$ — $(NH_4)_2A''$: granular crystals turning red in air (Deichsel; cf. Engel, C. R. 93, 628).— $(NH_4)_2A''$ aq. Obtained by evaporation *in vacuo* over H_2SO_4 .—Needles (Petrieff).— Na_2A'' aq: thin laminae, v. sol. water.— CaA'' aq: white pp. insol. dilute acetic acid.— CaA'' 4aq (dried at 100°) (Petrieff).— BaA'' aq (dried at 110°). White crystalline powder, v. sl. sol. water.— BaA'' 1½aq.— BaA'' (dried at 180°).— $(HO.Pb)_2A''$: nearly insol. water.— Ag_2A'' aq: amorphous pp. changing to minute needles. Explodes when heated.

Ethyl ether Et_2A'' aq. From the silver salt and EtI. Oil.

Di-acetyl derivative of the ethyl ether $(\text{CO}_2\text{Et})_2\text{C}(\text{OAc})_2$. [145°]. From the ether (1 mol.) and AcCl (2 mols.) at 100° (P.). Long needles. Partially decomposed by fusion and by solution in water.

Di-acetyl derivative $\text{O}(\text{OAc})_2(\text{CO}_2\text{H})_2$. [130°]. From $(\text{CO}_2\text{Et})_2\text{C}(\text{OAc})_2$ and dilute alcoholic KOH . Needles. Its alkaline salts are v. sol. water; its silver salt $\text{Ag}_2\text{O}_2\text{H}_2\text{O}_2$ is an insoluble powder.

Amide $\text{O}(\text{OH})_2(\text{CONH}_2)_2$. Deliquescent tables, which turn red in the air.

• *Phenyl-hydraside*

$\text{PhHN}:\text{C}(\text{CO}_2\text{H})_2$. [158°–164°]. From mesoxalic acid and phenyl-hydrazine hydrochloride in dilute acid solution (Elbers, A. 227, 355). Crystals.

Phenyl-hydraside of the Nitrile

$\text{PhHN}:\text{C}(\text{CN})_2$. [185°]. May be formed from the oxim-phenyl-hydraside of glyoxylyl-cyanide $\text{HO}_2\text{N}:\text{OH}:\text{C}(\text{N}_2\text{HPh})_2\text{CN}$ by dissolving in POCl_3 , heating with PCl_5 , pouring into ice, and treating the crystals with ether and alkali (Von Pechmann & Wehsarg, B. 21, 8001). Yellow needles (from ether-ligroin). Turns brown at 126°. Sol. hot water, alkalis, and the usual menstrua. Conc. H_2SO_4 forms a blood-red solution not changed by FeCl_3 . On warming with conc. HClAq it forms yellow needles of $\text{C}_6\text{H}_5\text{N}_3\text{O}$ [245°].

MESOXALIC ALDEHYDE $\text{CHO}.\text{CO}.\text{CHO}$.

Oxim $\text{HON}:\text{CH}.\text{CO}.\text{CH}:\text{NOH}$ or $\text{ON}.\text{CH}_2.\text{CO}.\text{CH}_2.\text{NO}$ v. DI-NITROSO-ACETONE.

Mesoxalic semi-aldehyde $^*\text{CHO}.\text{CO}.\text{CO}_2\text{H}$. *Glyoxylyl carboxylic acid*.

Diphenyl-hydraside $\text{CH}(\text{N}_2\text{HPh})_2\text{C}(\text{N}_2\text{HPh})_2\text{CO}_2\text{H}$. [203°]. From di-bromo-pyruvic acid in aqueous solution and phenyl-hydrazine hydrochloride (Nastvogel, A. 218, 87). Reddish-yellow needles (from hot alcohol), almost insol. water, sl. sol. ether and chloroform, v. sol. hot alcohol, acetone, benzene and HOAc . Dyes wool and silk yellow. Cold conc. H_2SO_4 forms a dark-red solution from which it is pptd. by water unaltered.

Di-p-tolyl-hydraside $\text{CH}(\text{N}_2\text{HC}_6\text{H}_4\text{Me})_2\text{C}(\text{N}_2\text{HC}_6\text{H}_4\text{Me})_2\text{CO}_2\text{H}$. [188°]. Formed in like manner. Golden needles (from benzene). Its alkaline salts are v. sol. hot, sl. sol. cold, water.

Nitrile $^*\text{CHO}.\text{CO}.\text{CN}$ v. *Glyoxylyl cyanide*.

Mesoxalic bromo-semi-aldehyde

$^*\text{CBrO}.\text{CO}.\text{CO}_2\text{H}$.

Methyl ether of the oxim $\text{CBrO}.\text{C}(\text{NOH})_2\text{CO}_2\text{Me}$. [c. 170°]. From dimethyl di-bromo-pyrrole di-carboxylate and HNO_3 at –18° (Ciamician & Silber, B. 20, 2601). Crystalline; sol. alcohol, m. sol. cold water, insol. petroleum-ether. Decomposed by fusion and by boiling with water.

MESOXALYL-UREA IS ALLOXAN. See also its compounds with METHYL-ANILINE, NAPHTHYLAMINE, and PYRROLE.

META. Use of this prefix applied to inorganic compounds; for *Meta-acids* and *Meta-salts* v. the acids or salts to the name of which *Meta-* is prefixed. Thus *Meta-phosphoric acid* will be found under **PHOSPHORIC ACIDS**, and *Meta-stannates* under **STANNATES**, a subdivision of the article **TIN**.

Names of *organic bodies* beginning with 'meta' will be found under the word to which 'meta' is prefixed.

METACETONE. The mixture obtained by distilling sugar with quicklime, called *metacetone* by Fremy (A. Ch. [2] 59, 6), is composed according to E. Fischer & Laycock (B. 22, 101) of propionic aldehyde, di-methyl-furfuran, and hydrocarbons.

METACETONIC ACID. An old name for **PROPIONIC ACID**.

METALBUMIN v. **PROTEIDS**, *Appendix O*.

METALDEHYDE v. **ALDEHYDE**.

METALLIC ACIDS. In the article **ACIDS** (vol. i. p. 47; cf. **CLASSIFICATION**, vol. ii. pp. 201, 202), it is shown that compounds of H with certain negative elements or groups of elements react with metallic oxides, hydroxides, and carbonates, in presence of water, to produce substances composed of metal, and the elements of the hydrogen compound excepting the H or a part of the H. Such hydrogen compounds are called acids. The negative elements which are found intimately combined with H in acids are fluorine, chlorine, bromine, iodine, oxygen, sulphur, selenium, tellurium; carbon always enters into the composition of those negative groups of elements which combine with H or with H and other elements to form acids. Only a few acids are binary compounds; the greater number are compounds of H with two or three other elements, among which are always found at least one of the eight negative elements enumerated above, or at least one of the negative carbon-containing groups of elements. By far the greater number of the more stable and definite acids are composed of H combined with non-metallic elements; but some acids have been isolated which are composed of H combined with metals and one or more of the eight strongly negative elements already enumerated, or one or more of the carbon-containing negative groups of elements. The following table gives the composition of most of those acids which contain metallic elements:—

Metallic acids.

H_2AsO_4	(H_2TiO_4)	H_2PtCl_6
HAsO_3	(H_2TiO_3)	H_2PtBr_6

H_2CoO_4	$\text{H}_2\text{Pt}(\text{NO}_2)_2$	$(\text{H}_2\text{ZnCl}_4)$
H_2CoO_3	$\text{H}_2\text{Pt}(\text{SCy})_4$	$(\text{H}_2\text{Zn}_2\text{O}_4)$
(H_2AlO_4)	H_2PtO_4	

The isolation of some of the acids in the fore-

going list is doubtful; these acids are placed in brackets. The compounds H_2AlO_3 and H_2ZnO_3 are also bracketed, because the reactions of these bodies show that they may be classed as feeble acids and at the same time as basic hydroxides.

An examination of the composition of the metallic acids shows that the reacting atomic aggregates of these compounds all contain a number of atoms of a negative element, or group of elements, which is large relatively to the number of atoms of metal present. The accumulation of negative atoms so modifies the functions of the H atoms that these are replaceable by metals, and this notwithstanding the presence of the positive metallic atoms. The H of the metallic hydrogen-containing compounds H_2CrO_3 ($=Cr_2O_3 \cdot H_2O$) and H_2CrO_4 ($=CrO_3 \cdot H_2O$) is not replaced by metals when these compounds react with metallic hydroxides or carbonates; but when 4 atoms of the negative O are associated with one atom of Cr and 2 atoms of H, the H of this compound (H_2CrO_4) is distinctly acidic. The negative character, or acid-forming character, of the groups CN and SCN is rendered evident by the number of acids which are formed by the union of these groups with H and metals.

If attention is paid to the general chemical characters of the metals which form acids it is seen that most of these metals occur in groups (using this term as it is used in the nomenclature of the periodic law) which also contain several distinctly non-metallic elements: thus Ti, Sn, and Pb belong to Group IV., which group contains C and Si; Cr, Mo, W, and U belong to Group VI., in which group also occur the negative elements O, S, Se, and Te; As, Sb, V, Nb, and Ta form part of Group V., which is distinctly negative in its general chemical character, and includes the markedly non-metallic elements N and P; Fe, Co, Ni, Au, and the Pt metals occupy a peculiar position in Group VIII. (cf. CLASSIFICATION, vol. ii. pp. 203-210; also IRON ELEMENTS, this vol. p. 66).

Several salts exist which, on account of their methods of formation and general stability, are probably best regarded as derivatives of metallic acids that have not yet been isolated; among such salts may be mentioned the stannous and zirconio-fluorides $M_2Sn(Zr)F_6$. Some chemists would class most, if not all, the double metallic haloid compounds as salts of metallic acids; e.g. $BiF_3 \cdot 3KF$ as the K salt of the acid H_3BiF_6 , $ZnCl_2 \cdot BaCl_2$ as the Ba salt of the acid H_2ZnCl_4 , and $MgI_2 \cdot KI$ as the K salt of the acid $HMgI_3$ (v. especially Remsen, *Am. J.* 11, No. 5).

The consideration of those metal-containing compounds which are acids brings out the inadequacy of that classification which would divide the elements into two classes only, metals and non-metals; it also well illustrates the difficulties of chemical classification, as shown by the way in which the chemical properties of an element are modified according to both the nature and the number of other elementary atoms with which that element is combined (cf. the article METALS in this vol. and CLASSIFICATION in vol. ii.).

M. M. P. M.

METALLOIDS. This name was at one time applied, most mistakenly, to the non-metallic elements. It is sometimes used to denote those elements which on the whole are non-metallic,

but yet closely approach the metals in some of their properties; As, Sb, Ti, V, Nb, Ta, for instance, are sometimes called metalloids. The term cannot be defined. There are certain elements which one chemist would class among metals, another would place with the non-metals, and a third would prefer to put into neither class, but call them metalloids.

M. M. P. M.

METALLURGICAL CHEMISTRY. The chemical reactions utilised in metallurgy are divisible into two distinct classes, viz. 'wet,' those which take place in aqueous solutions, and 'dry,' those which take place in furnaces, or their equivalent, at a relatively high temperature. The present tendency is more and more in the direction of combining these two methods, metals being now frequently extracted from their ores partly by wet processes and partly by dry processes.

The ore of any metal may be defined as a collection of mineral substances containing that particular metal in sufficient quantity to pay for its extraction on a commercial scale. Although each metallic element exists in nature in a great number of combinations, yet very few of these compounds occur in sufficient quantity to be of direct importance to the metallurgist, except in so far as they may tend to introduce impurities into the metal to be extracted.

Chemically, ores may be broadly divided into three classes, containing respectively—I. NATIVE METALS, i.e. metals uncombined with any non-metallic element. II. SULPHIDES and ARSENIDES. III. OXIDES, including carbonates and silicates.

Class I. NATIVE METALS. A native metal may be separated from its ores in one of four ways. (a) By Liquefaction. In order that this may be done it is essential that the metal be fusible at a temperature insufficient to cause the earthy portions of the ore to frit or agglomerate; e.g. Bi. (b) By fusing the ore, when the metal will sink to the bottom by reason of its high S.G.; e.g. Bi, Cu. (c) By dissolving the metal out by means of another metal; e.g. Au, Ag, Pt. These metals may be dissolved out of their ores by Pb, which is then removed by cupellation, or, in the case of Ag, the separation of the Ag from the Pb may be effected by Zn, which does not alloy with Pb, and being specifically lighter rises to the surface, carrying the Ag and some lead with it. The Zn is subsequently distilled off, and the residual Ag and Pb cupelled. Similarly, Au and Ag may be dissolved out by Hg, which may then be distilled off. (d) By dissolving the metal by means of an acid or a gas in solution; e.g. Au extracted by a solution of Cl, and Pt, Pd, Ir, Rh, and Ru by aqua regia. The Au and Pt may be refined by wet processes, taking advantage of the fact that Au and Pt are insoluble in sulphuric, hydrochloric, and nitric acid, when these acids are used separately, but are soluble in aqua regia, while the Ag, Cu, Pb, and Fe are freely soluble in one or other of the three acids named. In 'parting' Au, sufficient Ag must be present to allow the acid free access to the impurities, which would otherwise be protected by the insoluble gold. Pt, when present in Au only in small quantity, may be separated by 'parting' with Ag, as under these conditions the Pt is

acted on by the 'parting acid.' If present in larger quantity, it must be ppd. from a solution. Ir may be separated from Au by difference of S.G., and from Pt it may be removed to a certain extent by using *aqua regia* of medium concentration, in which it is not freely soluble. Pt is ppd. from its solutions as a double salt of Pt and NH_4 by adding NH_4Cl . Pd, if present, may be ppd. before the Pt by neutralising with Na_2CO_3 and adding HgCy_2 . Ir, if it has gone into solution, will not be ppd. with the Pt, but its double salt is difficult to wash out. Pd, Rh, Ru, and Os will also be found with the Ir in solution after the Pt has been ppd. Rh may be removed completely by fusing the platinum double chloride with KHSO_4 and a small quantity of NH_4HSO_4 . Ir may be ppd. at the same time as platinum by KCl , and the pp. fused with K_2CO_3 , which will oxidise the Ir and not the Pt. Remove the potassium salt by boiling water, and then dissolve out the platinum with *aqua regia*, in which the oxide of Ir is insoluble. Ir may also be separated from the pp. by KC_2 , the Ir salt being soluble while the Pt salt is insoluble. Pt is obtained in the metallic state by carefully heating the double chloride, which then breaks up. Au is ppd. from its solutions as metal by FeSO_4 , SO_2 , Ag , or $\text{H}_2\text{C}_2\text{O}_4$. For dental purposes, Au is frequently deposited by electrical means. Ag is first thrown down as chloride, which is afterwards reduced by Cu, Zn, or Fe. Au, containing not more than 10 p.c. Ag, is also refined by Miller's process, at the Australian Mint, in the dry way, by passing Cl into the molten gold. The impurities As, Sb, Bi, Pb, and Zn are converted into chlorides, which volatilise, and the Ag becomes AgCl , which forms a fused layer on the surface of the gold.

Class II. SULPHIDES AND ARSENIDES. Dry methods. Sulphides and arsenides are either (a) *infusible*, at such temperatures as can be obtained in furnaces on the large scale; (b) *fusible*; or (c) *volatile without fusion*.

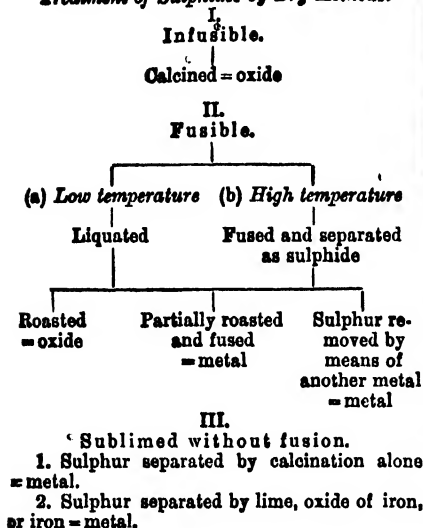

(a) *Infusible sulphides.* In these cases the S must be replaced by O, as an infusible sulphide cannot be properly reduced to the metallic state. This is done by calcining or roasting the ore, so that air has free access to it. The sulphide is oxidised to a sulphate at low temperatures, and at higher temperatures the sulphate breaks up into SO_2 and an oxide of the metal. Practically there is only one sulphide under this head, viz. ZnS , *sinc blende*. For the subsequent treatment of the oxide v. 'oxide class.'

(b) *Fusible sulphides.* Sulphides and arsenides of this class may be subdivided as follows:—(i) *those which are fusible at a very low temperature, insufficient to produce fritting, i.e. incipient fusion causing agglomeration of the constituents of the ore*; (ii) *those requiring a higher temperature, at which fritting would take place*. A sulphide in division (i) may be liquated out, e.g. Sb_2S_3 . The sulphides and arsenides belonging to (ii) may be separated by fusing the ore, when the sulphide or arsenide would collect together beneath the slag; e.g. sulphide of copper (*copper pyrites*); arsenides of nickel and cobalt (if sufficient arsenic is not present in the ore more is added), the arsenide separates in a distinct layer from the sulphides of other metals during the

fusion; sulphide of nickel obtained by fusing nickel ores, or products, free from arsenic, with iron pyrites. The sulphides and arsenides thus separated from the gangue would next be treated in one of the following ways:—1. *Converted into oxide by roasting*; e.g. Sb_2S_3 , *copper matte*, arsenides of nickel and cobalt (the arsenious acid being condensed in coke towers), sulphides of nickel and cobalt free from arsenic; the oxides of nickel and cobalt are subsequently treated in the wet way. 2. *Partially roasted to form a certain amount of oxide and sulphate, and then fused*; the oxygen of the oxides combines with the sulphur of the sulphides and arsenides, forming SO_2 , and liberating the metal; e.g. Sb_2S_3 and PbS . In the case of the double sulphide of Cu and Fe, the Fe is first removed by a series of calcinations and fusions, S passing to the Cu and O to the Fe, the oxide of iron thus formed uniting at the same time with silica to form slag. This process goes on so long as any iron remains. As soon as the iron is all removed, the reaction between Cu_2S , CuO , and Cu_2O takes place, liberating metallic copper. The principal impurities in copper ores likely to pass into the Cu are As, Sb, Zn, Pb, Bi, Sn, Ni, Co, Au, and Ag. The greater proportion of these present either volatilises or becomes oxidised and removed in the slags. Au and Ag, being neither appreciably volatile under the conditions nor oxidisable, become concentrated in the copper. It is particularly difficult to get rid of the last traces of As and Bi. The use of a basic lining to the furnace—say, dolomite—greatly facilitates the removal of As in the slag. The elimination of As is also assisted by the use of 'soda nitre' in refining. Bi can most readily be removed by what is known as the *best-selecting process*, in which advantage is taken of the circumstance that copper has a greater affinity than bismuth for sulphur. This process comes in just before the copper is first reduced from the sulphide. A little copper is made to separate by the reaction between sulphide and oxide; this throws out and collects as 'bottoms' the bismuth, tin, lead, and antimony.—3. *Fused in the presence of another metal which combines with, and so removes, the sulphur*; e.g. sulphides of Bi, Pb, and Sb treated with Fe; Ag separated by metallic Pb from sulphide of Pb containing sulphide of Ag. Copper can only be partially separated from sulphur in this way, a double sulphide forming which cannot be reduced by iron.

The operations described under (i) and (ii) are in some cases applied directly to the ore without first separating the sulphide by liquation or fusion.

(c) *Sulphides volatile without fusion.* Amongst the metallic sulphides there is only one which sublimates without fusion, viz. HgS . When heated in presence of air HgS yields SO_2 and Hg . As the Hg has no tendency to combine with oxygen under these conditions, and is volatile at a very low temperature, it distils over, and may readily be condensed. For these reasons advantage is not taken of the fact that the sulphide is itself volatile, it being simpler to distil the metallic mercury direct from the ore. The sulphur is sometimes removed by roasting the mercury ore with lime or oxide of iron.

Treatment of Sulphides by Dry Methods.

Wet processes for sulphides and arsenides. The sulphide and arsenide ores of Ni, Cu, and Co are partially, and those of Cu and Ag partially or wholly, treated by wet methods. In these processes the metal is first made to form a soluble compound. This may be done by roasting the ore with, or in some cases only mixing it with, some compound, which by double decomposition will convert the metal to be extracted into a soluble compound. In other cases it is done by roasting the ore alone at a low temperature, or even by simply exposing it to the action of the atmosphere without using artificially produced heat; in either case the sulphide will be converted into a sulphate; e.g. *copper pyrites* and *silver ores*.

Thus, soluble sulphate of copper may be formed by roasting copper pyrites or more slowly at the ordinary temperature of the atmosphere. About one-third of the copper extracted in this country is obtained from Spanish pyrites, averaging only 8-4 p.c. of copper, by roasting the burnt ore—received from the sulphuric acid works—with common salt, which reacts with the CuSO_4 produced during the burning, to form CuCl_2 , which is then dissolved out, together with the chlorides of Ag, Pb, and Au, these metals being present to a small extent. The Ag is thrown down, along with Au and Pb, by a soluble iodide, KI or ZnI_2 . The iodine is removed from the AgI by Zn. Finally the Cu is pptd. by addition of iron.

The reactions which take place in the wet treatment of silver ores are of special interest and importance. They are divisible into three classes.

I. *The insoluble silver compound is decomposed and the Ag amalgamated while still in the ore ('free milling ore'), without the aid of any furnace-operation whatever.* If there is much S or As present the ore, where practicable, is first roasted with salt. Under this head are included all the amalgamation-processes.

II. *The insoluble silver compound is converted*

into sulphate by roasting alone and washed out with water; or the Ag is converted into chloride by roasting with common salt, and washed out by a solvent for chloride of silver. Under this head are included the Augustin, Ziervogel, Von Paterna, and Russell processes.

III. *The insoluble silver compound is converted into a soluble compound by the action of certain salts in solution without roasting the ore or employing any furnace-operation whatever.* This class includes the Von Paterna process when applied to 'amalgamation tailings,' and the Russell process applied to both ores and tailings.

The amalgamation-methods without roasting have been of great service where fuel is scarce, as in Mexico. These methods depend on the power of certain salts, such as the chlorides of Cu, to decompose Ag_2S . If mercury is present at the same time, the AgCl will be reduced and the Ag taken up by the excess of Hg, from which it can be separated by squeezing and distillation. Iron or Cu may be employed to decompose the AgCl, Hg being used only to collect the Ag. This reduces the loss of Hg, but to bring about sufficient contact, more power, and consequently more fuel, is required. Where fuel is available there is often great advantage in roasting the ore with salt before amalgamation.

Where possible the amalgamation-methods have been superseded by the other wet processes included under heads II. and III., viz. the Augustin, Ziervogel, Von Paterna, and Russell methods.

The Augustin process. Ore or regulus is first partially roasted, and then undergoes further roasting with common salt, the AgCl thus formed being washed out with NaClAq and pptd. by Cu. The Ag is usually first concentrated in copper mattes.

The Ziervogel process. This method depends on the difference between the temperatures required to break up the sulphates of different metals. Thus by suitably regulating the temperature, the sulphates of Fe, Cu, &c., formed by roasting mattes at a low temperature, may be decomposed into oxides and SO_2 , while the sulphate of Ag will be unaltered, and can therefore be extracted by warm water, and then pptd. as in the previous method. The regulation of the temperature throughout a large furnace is obviously a point requiring considerable skill. For this reason, in practice, mattes are usually first worked by the Ziervogel process, and the residue extracted by the Augustin method.

Von Paterna process. The soluble salts produced by roasting the matte are first dissolved out with water, after which the matte is further roasted with NaCl, and the AgCl washed out with $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ or $\text{CaS}_2\text{O}_3\text{Aq}$, from which solution the Ag is pptd. by a soluble sulphide or SH_2 . The silver is reduced from the Ag_2S , either by roasting or by boiling with freshly slaked lime, forming calcium polysulphide. When there is much of the base metals present, more particularly lead, the Von Paterna process is not so suitable. The lead is mostly present as sulphate after roasting, and this is soluble in $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$. Some of the most important objections to the Von Paterna process, as applied to poor ores containing base metal, are obviated in the process next described.

The Russell process. In this process what is known as the '*extra solution*' is used, in addition to or in substitution for that ordinarily employed in the Von Patara process. The '*extra solution*' is prepared by making solutions of $\text{Na}_2\text{S}_2\text{O}_3$ and CuSO_4 , containing respectively 18 parts of the former and 10 parts of the latter salt, and mixing them together. The pp. after washing is dissolved in a solution containing 1-2½ p.c. $\text{Na}_2\text{S}_2\text{O}_3$. Although this '*extra solution*' is not so good a solvent for AgCl as $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$, yet it acts energetically on native silver and the compounds of silver with S, As, and Sb. Owing to the want of permanence special precautions have to be taken in using this solution. To get the best effect the solutions should be used warm. In order to obtain finer billon by this process, advantage is taken of the fact that PbCO_3 is not soluble in the solution, although other salts of lead are soluble. Na_2CO_3 , free from NaOH and Na_2S , is added to the solution containing the silver and lead which have been washed out. It is stated that the whole of the Pb may thus be removed. Carbonate and sulphate of Cu are the only compounds of Cu likely to occur which are soluble in the '*extra solution*.'

It is probable that this process in the near future will supersede very largely the fusion and amalgamation-processes, besides which it is applicable to ores which cannot profitably be treated by either of the other methods. The cost of the necessary chemicals is much less than that due to loss of mercury; in addition to which, lead and copper are lost in the older processes and saved in the Russell process.

In some cases the ores may be treated direct by the Russell process without previous roasting, and both the Von Patara and Russell methods are largely used in the treatment of '*tailings*' from amalgamation.

Nickel and cobalt. It has been seen that these metals may be separated from others as arsenide. In practice, however, the separation is not so complete, some of the nickel and cobalt passing into the regulus, and some of the other metals into the *speise*. The following are the reactions usually employed to separate the various metals from one another. The calcined *speise* is treated with HClAq . The resulting solution, which will contain Ni, Co, Fe, Cu, Pb, Bi, and As, is diluted, and oxidised by bleaching-powder, the proportion added being adjusted by a rough analysis. Milk of lime is added to the requisite extent to throw the iron down as sesquioxide, any arsenic present at the same time ppg. as basic arsenate of iron. The solution is next treated with SH_2 , to ppt. Cu, Pb, and Bi, after which the Co can be thrown down as sesquioxide by a further addition of bleaching-powder, and subsequently the Ni pptd. as hydrated oxide by the addition of milk of lime.

Class III. OXIDES; INCLUDING CARBONATES AND SILICATES. Ores of this class are reduced to the metallic state by means of carbonaceous matter such as charcoal, coal, or coke, or by means of the gaseous product of the incomplete oxidation of carbonaceous matter, viz. carbon monoxide.

The only exceptions among the oxides of the commoner metals are Al_2O_3 and MgO . These oxides cannot be reduced to the metallic state in this way; they have to be converted into

double chlorides, from which, while in a state of fusion, the metals are liberated by metallic sodium, or by electrolysis. The metals, the oxides of which are in practice reduced by carbon or CO, are Sn, Fe, Ni, Co, Mn, Cr, W, and Zn. Of these Sn and Zn present the simplest reactions. The reactions in the other cases are complicated by the fact that all these metals combine more or less freely with carbon. When it is desired to obtain the metals in the most malleable condition, i.e. free from carbon, the fact that the oxides and the carburised metals react with one another eliminating both the carbon and the oxygen, as CO and CO_2 , is utilised. Every iron- and steel-making process is dependent on this reaction. According as the conditions are made more or less favourable to carburisation, or decarburisation, so will the resultant metal be either cast-iron, hard steel, mild steel, or malleable iron. It is possible to reduce the oxides under consideration to the metallic state, and also to carburise the metals, by the action of CO, without the metals becoming fused. The oxides are first reduced, and then carburised by the dissociation of some of the CO. The liberated oxygen combines with CO and is thus removed. Nickel is thus reduced to the metallic state, more or less combined with carbon; and bars of metallic iron are carburised to produce 'cementation' steel. In a similar way a carburised metal may be decarburised by O or CO_2 ; in this way 'malleable cast-iron' is made. Whether the action consists of carburising or decarburising is entirely dependent on which agent preponderates at the time in the atmosphere surrounding the body.

Reactions for removal of 'impurities' from metals of oxide class. The refining of Ni and Co, as we have seen, precedes the reduction to the metallic state. The refining of Sn is effected after reduction, partly by liquation and partly by oxidation, by which means the principal impurities, Fe, As, and W, are removed. Mn and Cr are reduced directly from their ores, in the form of alloys with iron, only pure ores being used. Tungsten is either reduced directly from the ore, alloyed with iron, or undergoes a preliminary purification and ppg. as oxide in the wet way. The impurities which it is important to remove from iron are S and P. The latter can only be passed into the slag when the slag is basic, and the conditions tend to oxidation. Thus, P is removed in the primitive iron making processes; also when iron is made by the '*finery*' and the '*puddling*' processes; also in making '*ingot-iron*' by the Siemens and Bessemer processes, when a basic lining to the furnace or converter is used. P is not removed in processes in which pig-iron or high-carbon steel is made, nor in the Siemens or the Bessemer processes when the furnace or converter is lined with siliceous material, and malleable metal is being produced. In the Bessemer process, with an '*acid-lining*,' the necessary heat for the process is obtained mainly by the oxidation of silicon in the pig-iron; when a phosphiferous pig-iron is used, and a '*basic-lining*,' most of the heat is obtained by the oxidation of the phosphorus and less silicon is required in the pig-iron. In both processes a portion of the heat is obtained from the oxidation of C. Sulphur can be removed econo-

mically only in the blast-furnace, because when treating pig-iron for the production of malleable iron the sulphur is one of the last substances to oxidise out, and its removal would result in a great waste of iron. To remove S in the blast-furnace the temperature must be high, and the conditions must be strongly reducing and carburising: i.e. the charge must contain plenty of charcoal, coal, or coke, and lime must be added to the charge in considerable quantity. Under these conditions the S combines with the Ca, and passes into the slag as sulphide.

SLAG REACTIONS. Slags consist of the non-metallic constituents of an ore or furnace-product, and of the useless or objectionable metallic elements. They are produced by simply fusing the ore alone, if it is in itself sufficiently fusible, or by fusing it with such materials—fluxes—as will bring about the requisite fusibility. Except in a few special cases, e.g. the reduction of aluminium or magnesium, slags consist of more or less complex silicates. In processes for making more or less malleable iron, the slags are composed mainly of silicates of Fe, Ca, Al, and Mg, with smaller proportions of silicates of Mn, alkalis, and alkaline earths. In pig-iron slags, the iron is comparatively small in quantity, or is even entirely absent when much lime is used. In other slags, excepting those produced in treating the 'noble metals,' iron will generally be present in large proportion.

ELECTRO-METALLURGY. Electro-metallurgical processes are divisible into two distinct classes: one class includes processes for the extraction of metals from their ores; the other includes processes for refining metals already extracted. Although a great many processes have been devised for the electrical extraction of metals, except for the extraction of aluminium and magnesium—in which cases the metals are first got into the condition of double chlorides, or, in the case of aluminium, sometimes of fluoride—there is not much prospect of such processes being successfully and economically worked, even when power can be obtained from waterfalls. By the Cowles process, according to Sterry Hunt, nearly pure Al is produced in small buttons, but up to the present it has been necessary to reduce some other metal with the Al to collect it together. In this process the Al_2O_3 and the oxide of the metal to be alloyed with the Al are mixed with carbon, and the mixture is placed round two carbon poles between which an electric discharge is made to pass.

The second class of processes has been advantageously applied to the refining of Cu, more particularly Cu containing small quantities of Au and Ag. In refining Cu electrically, the electrolyte is usually $CuSO_4$, kept at as uniform a temperature and concentration as possible; the anode being formed of the copper to be refined, pure copper depositing on the cathode. The silver and gold collect at the bottom of the tank as a muddy deposit.

A. K. H.

METALS. An element is a definite and distinct kind of matter which has resisted all attempts to separate it into unlike portions. The classification of the elements, in accordance with their chemical properties, necessarily carries with it the classification of many compounds, inasmuch as the chemical properties of an ele-

ment cannot even be stated without considering the composition, general chemical behaviour, and conditions of formation, of compounds of that element. For instance, certain elements are placed in the same class because they all form hydroxides which are alkalis: this statement implies an acquaintance with the composition, methods of production, and chemical properties, of the alkalis; but one of the chemical properties of an alkali is that it neutralises acids, and in so doing forms salts; hence it is necessary to know something about acids and salts, in order to understand what is meant by an alkali, or by an alkali-forming element.

The elements may be classified in accordance with their physical properties. If a binary compound is electrolysed, one of its elements separates at the positive electrode, and the other at the negative electrode (secondary reactions which may occur are supposed to be overlooked). That element which separates at the positive electrode is said to be electro-negative to the other element. By studying the electrolysis of binary compounds, the elements may be arranged in an electrical series. This series may be divided into two parts: all the elements on one side of any chosen element are electro-positive to all the elements on the other side of the chosen element. Taking hydrogen as the central element we are able to subdivide the elements into two classes; all the elements on one side of H are electro-positive to the elements on the other side of H. Thus we arrive at a classification of the elements founded on one chemico-physical property. Now we find that the electro-positive elements, on the whole, more resemble one another in certain physical properties, and also in their general chemical character, than they resemble the electro-negative elements. Those elements which are electro-positive to H as a class are greyish-white in colour, lustrous, fairly malleable and ductile, comparatively good conductors of heat and electricity; those elements which are electro-negative to H vary much in colour and appearance, they are not usually lustrous, they are generally brittle, and they do not conduct heat or electricity well. Turning to the chemical characters of the two classes of elements, we find that those placed in the electro-positive class generally combine with O to form basic oxides; their compounds with O and H are also usually basic; they do not, as a rule, enter into the composition of acids; very few of them form hydrides; their haloid compounds, as a whole, are tolerably stable as regards the action of heat, and they are not readily decomposed by water; if they are thus decomposed they generally produce oxyhaloid compounds; speaking broadly, these elements do not exist in allotropic forms. On the other hand, we find that most of the elements which are placed in the electro-negative class combine with O to form acidic oxides; their compounds with H and O are usually acids. All acids contain one or more of these elements; they generally form hydrides; many of their haloid compounds are decomposed by heat, and many of them are also decomposed by reacting with water, thereby producing haloid acids and either oxides or oxyacids of the electro-negative elements; speak-

ing broadly, these elements exhibit the phenomena of allotropy.

Hence, it would appear that the division of elements into two classes, those which are electro positive to H, and those which are electro-negative to H, is a good classification, because with this one class-mark many other properties, both physical and chemical, are associated.

The electro-positive elements are called metals; the electro-negative elements are called non-metals.

A further examination of metals and non-metals shows that the classification implied in these terms is very far from being sufficient for chemical purposes. We cannot define the term metal; just as we cannot define any of the chemical names which are given to classes of bodies. We can sketch the ideal metal. Considered physically, the ideal metal is a hard, fairly heavy, greyish-white, lustrous, malleable, ductile, and tenacious solid, which melts only at a high temperature; it is a good conductor of heat and electricity; it crystallises in forms belonging to the regular system; its emission-spectrum consists of lines, and is comparatively simple in character. Considered chemically, the ideal metal is hardly, if at all, changed in the air, it combines with O at fairly high temperatures, and forms one or more oxides which are basic, i.e. which react with acids to form salts; it reacts with water or steam to produce an oxide or hydroxide and evolve H; no hydride of the ideal metal is known; it does not enter into the composition of acids, but it reacts with acids to form salts; its sulphides react with acids to produce salts and evolve H_2S , they combine with the sulphides of decidedly electro-negative elements; the salts of the ideal metal are numerous and stable; it forms but few acid salts, but the number of double salts into which it enters is large; it combines directly with the halogens, producing compounds which are volatilised without decomposition at rather high temperatures, and which dissolve in water without change; the ideal metal forms alloys with elements of its own class, which alloys belong rather to the group of physical, than to that of chemical, compounds; lastly, the ideal metal exists in only one modification, i.e. it does not show allotropy. The ideal non-metal is the opposite, chemically and physically, of the metal.

No element exhibits all the properties which we have placed in the category 'metal'; nor is there any element which possesses even some of these properties without at the same time also possessing some of the properties which belong to the typical non-metal.

The elements sodium and potassium possess most of the chemical properties enumerated as characteristic of metals; but these elements are instantly oxidised by exposure to air; they probably form unstable hydrides; they are very soft, lighter than water, and melt at moderately low temperatures.

The element gold possesses most of the physical properties characteristic of metals; but its hydroxide reacts with alkalis to form salts, e.g. $KAuO_2$; Au also forms the acids $HAuBr_3$ and $HAuCl_4$; Au_2S combines with the sulphides of

the very metallic elements K and Na to form salts. The element chromium exhibits many of the characteristic physical properties of metals; it also decomposes steam with evolution of H; it combines with the halogens to form stable compounds, some of which have been gasified at high temperatures; chromium does not form a hydride; the oxides CrO and Cr_2O_3 are basic; the element reacts with many acids to form salts, which are well marked, stable compounds; it does not exist in allotropic forms. On the other hand, CrO_2 is a distinctly acidic oxide, reacting with water to form the acid H_2CrO_4 , from which is obtained a large number of salts. In other words, chromium belongs to the class metals, and also to the class non-metals. In an even more marked way than Cr, manganese combines in itself both metallic and non-metallic properties.

The chemical properties of an element depend on the properties of the other elements with which it combines, and on the relative quantities of these other elements entering into combination. It is this fact which makes it impossible to apply the definition of metal or non-metal, in its entirety, to any element. The classification of elements into metals and non-metals is nevertheless a useful one, provided it is employed with judgment and knowledge. If we find that a certain element is hard, lustrous, unaltered or only slowly changed in the air, and is a good conductor of electricity, or if we find that the oxide of a certain element is basic, and that the chloride is not decomposed by water, or if decomposed produces an oxychloride, we have at once a guide to lead us in our further examination of the element. We shall probably find that the element in question possesses several of the other physical characteristics of metals; and we shall also probably find that it reacts with acids to form salts, decomposes steam with evolution of H, produces at least one sulphide which combines with sulphides of some of the negative or non-metallic elements, and so on.

The following division of the elements usually placed in the class metals is that arising from the application of the periodic law.

CLASS I. division 1;	Li Na K Rb Cs
" 2;	Cu Ag Au.
CLASS II. division 1;	Be Ca Sr Ba
" 2;	Mg Zn Cd Hg.
CLASS III. division 1;	Sc Yt La Yb
" 2;	Al Ga In Tl.
CLASS IV. division 1;	Ti Zr Ce Th
" 2;	Ge Sn Pb.
CLASS V. division 1;	V Nb Di Ta
" 2;	As Sb Er Bi.
CLASS VI. division 1;	Cr Mo W U
" 2;	none isolated.
CLASS VII. division 1;	Mn
" 2;	none isolated.
CLASS VIII. division 1;	Fe Ni Co (Cu)
" 2;	Rh Ru Pd (Ag)
" 3;	Os Ir Pt (Au)

The metals in division 1 of Class I. are generally known as the *alkali metals*. They possess in the most marked way the chemical characters of the ideal metal; none of their compounds exhibits any acidic functions; they are electro-positive to all the other elements. The metals

in division 2 of Class I. are very distinctly metallic in their physical properties; chemically considered they show considerable differences among themselves; several compounds of gold are almost non-metallic in their reactions, the chemical and physical analogies of this element are best represented by placing it both with Cu and Ag, and also with Os, Ir, and Pt, in division 3 of Class VIII.

The *alkaline earth metals* which form division 1 of Class II. are more metallic in their physical properties than the metals placed in division 1 of Class I.; chemically they are also distinctly metallic. Coming to Mg, Zn, Cd, and Hg, which form division 2 of Class II., we have four elements whose properties closely approach those of the ideal metal; Cd may be taken as on the whole the best actual representative of the class metal. As we pass to the higher classes we find many metals exhibiting properties characteristic of non-metals, until in Class VII. we arrive at Mn, an element which is at once distinctly metallic and decidedly non-metallic in its chemical properties.

In connexion with the subject of this article, references should be made to the following articles wherein the different classes of metals are described:—ALKALINE EARTHS, METALS OF THE, vol. i. p. 112; ALKALIS, METALS OF THE, vol. i. p. 115; CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168; COPPER GROUP, vol. ii. p. 250; EARTHS, METALS OF THE, vol. ii. p. 424; IRON GROUP, vol. iii. p. 66; MAGNESIUM GROUP, vol. iii. p. 163; NITROGEN GROUP (for Class V., V to Bi), vol. iii. *infra*; NOBLE METALS, vol. iii. *infra*; TITANIUM GROUP, in vol. iv.; TIN GROUP, in vol. iv.

M. M. P. M.

METALS, RARE. Under this name are included a number of presumed elementary bodies concerning which our knowledge is at present very imperfect. We see that in their general properties they approximate more or less closely to cerium, yttrium, and lanthanum, but we are not sure how far we have yet obtained them in a state of purity. Consequently we are in doubt not merely as to their at. w. and S.G., but even as to their number and their rank as elements, compounds, or mere mixtures. Our ignorance is due to the great rarity of these bodies, to the high complexity of the minerals in which they are found, but most of all to the fact that they differ among themselves merely by very minute shades.

The principal sources of the rare metals are *adolinite*, *keilhauite*, *fergusonite*, *euxenite*, *cerite*, and *thorite*, which are Norwegian minerals, and further, *samarskite*, which was first obtained from the Urals, but has since been found in relatively large quantities in North Carolina. It is to be noticed that specimens of any one of these minerals, if from different localities, are not identical in the earths they contain. Hence if it is desired to isolate any particular earthy it is best to select as the first material that mineral in which nature has, so to speak, commenced the task of separation. (This method was proposed by the writer in his address to the chemical section of the British Association, Birmingham Meeting (*C. N.* 54, 128; *ibid.* 54, 157; *Pr.* 40, 505.) Nilson and Kriss have since adopted and recommended the same method (*B.* 20,

2184; *C. N.* 56, 74, 85, 135, 145, 154, 165, 172).

The recognition of the various rare earths is a matter of no little delicacy. Here spectroscopy in its several modifications renders the greatest service. In endeavouring to ascertain by this means what substances are present in a mineral containing rare earths, chemists may employ either the spark-spectrum, the absorption-spectrum, or the incandescence- or the phosphorescence-spectrum. They may further apply any of these tests either at once to the original matter, or to some of its portions after a partial separation has been effected by chemical treatment. The question of course arises, how are we to know when we have obtained any one earth separated from all other bodies, and absolutely pure? In the case of those earths and their solutions which present an absorption-spectrum, *e.g.* didymia, samaria, holmia, erbia, &c., the writer has shown that as an element approaches simplicity the absorption-spectrum of its solutions will become less and less complicated; hence it would appear that when absolutely free from its associates, each element would have an absorption-spectrum of great simplicity, in many cases consisting of one band only (the 'one band, one element' hypothesis). But as certain earths, *e.g.* lanthana, mosandra, philippia, scandia, terbia, &c., give no absorption-spectra, this test is not applicable in all cases.

Great caution is required in drawing conclusions from the examination of spectra. Concerning the influence of one body upon another little is yet known, but that little is of sufficient importance to make us very careful how we interpret absorption-spectra when not corroborated by chemical results. Lecoq de Boisbaudran and J. Lawrence Smith have pointed out some important modifications produced in absorption-spectra by the presence of an excess of acid in the solution (*C. R.* 88, 1167). Sorot subsequently verified these observations. Brauner and others have put on record experiments on mixing solutions of didymium and samarium. They find in the case of a didymium solution showing the group of three bands, 476, 469, 428 [$1/\lambda^2$ 430.4, 441.3, 454.6], that, by adding a dilute solution of samarium, these three bands vanish, without the appearance of any of the samarium bands, until a certain proportion is reached, when the samarium bands gradually come into their places (Brauner, *C. J.* 43, 286).

Many of the earths that do not yield solutions giving absorption spectra can be made to give characteristic spectra by phosphorescence. This is known as the 'radiant matter' test. When the spark from a good induction-coil traverses a tube having a flat aluminium pole at each end, the appearance of the spark changes according to the degree of exhaustion. If atmospheric air is the gas under exhaustion, at a pressure of about 7 mm. a narrow black space is seen to separate the luminous glow and the aluminium plate connected with the negative pole of the induction-coil. As the exhaustion proceeds this dark space increases, until at a pressure of about 0.02 mm. the dark space nearly fills the tube; the luminous cloud showing the presence of residual gas has almost disappeared, and the molecular discharge from the negative pole

begins to excite phosphorescence on the glass where it strikes the side. There is a very wide difference in the degree of exhaustion at which various substances begin to phosphoresce. Under the influence of this discharge of 'radiant matter,' a great many substances emit, more or less intensely, a phosphorescent light. On examining this light in the spectroscopic, most of these bodies give a faint, continuous, spectrum with a more or less decided concentration in some one part, the superficial colour of the phosphorescing substance depending on this preponderating emission in one or other part of the spectrum. Sometimes, but less commonly, the spectrum of the phosphorescent light is discontinuous.

If we examine the 'rare earths' by this 'radiant matter' test we find they present phenomena of a striking character. Some of them remain unaffected, and are thus at once referred to a distinct group. Others, such as thorium, do not phosphoresce and offer great obstruction to the passage of the spark. Other earths become very phosphorescent and vary greatly in their power of retaining a residual phosphorescence. On examining phosphorescent earths glowing in a vacuum tube, the writer found remarkable differences in the duration of this residual glow. Some of the earths remain luminous for many minutes after the cessation of the current, while others cease to phosphoresce immediately on the stoppage of the current. Take the case of yttria. This earth, the writer finds, can be resolved by chemical treatment into a series of simpler bodies of unequal basicity, to which he has given the provisional designations of Ga, G β , G δ , G ζ , G η , and S γ . The after-glow of these bodies differs somewhat in colour from that which the earth exhibits while the current is still passing. The spectrum of the after-glow also shows that some of the lines are missing. In the electrical phosphoroscope—an instrument similar to Becquerel's phosphoroscope, but having the substance acted on electrically instead of by direct light—the different bands of the new constituents of yttria (*v. infra*) do not all appear at the same speed of rotation. At the lowest speed the double greenish-blue band of G β is first seen, followed next by the dark-blue band of Ga. As the velocity increases there follows the bright citron-yellow band of G δ , and as the utmost speed approaches the red band of G ζ is seen, but not without difficulty. As another instance, if lanthanum sulphate with traces of Sm as impurity, along with a little lime is examined in the phosphoroscope, the band of G ϵ is visible at the lowest speed; G δ follows at an interval of '0035 second, and the Ga band immediately afterwards. All the earths of the yttrium and samarium groups yield discontinuous spectra when submitted to the induction discharge *in vacuo*.

A modification of phosphorescence-spectroscopy is produced by the previous addition of other earths to the specially phosphorescent earths. Lime exerts a remarkable action. By itself, it phosphoresces with a continuous spectrum, while yttria phosphoresces with a discontinuous spectrum. But if these two bodies are mixed together, the phosphorescing energy of the lime does not extend over the whole spectrum,

but concentrates itself in strengthening the yttria bands. These bands become broader, but at the same time less sharply defined, in proportion as the lime is increased in quantity. Lime also brings out the phosphorescent bands of samaria. It also suppresses the sharp line S δ , the most striking feature in the phosphorescent spectrum shown by pure samarium sulphate. On the other hand an addition of 'old' yttria deadens the other lines of samaria, but brings out the line S δ more strongly. Lanthanum sulphate in the 'radiant matter' tube phosphoresces with a reddish colour. If lime is added to lanthanum sulphate the phosphorescence changes its colour from red to yellow. Lime also brings out the bands of yttrium and samarium if these are present as impurities. So sensitive is this test that it will show the presence of one part of yttria or samaria in more than a million parts of lime. When G δ , Ga, and G β are present in small proportions with lime the bands of G δ and Ga become intensified, but a dark space appears instead of the green band of G β . Hence if only a small trace of G β is present in lime the green band is not only obliterated, but the quenching action suppresses that part of the continuous lime-spectrum which has the same refrangibility as the G β line, and thus gives a black space in the spectrum.

There are many instances of the modifications induced in the normal spectrum of one earth by the admixture of others when treated as anhydrous sulphates. One of the most striking instances is that of a mixture of samaria with yttria, since the presence of even 40 p.c. of yttria practically obliterates the spectrum of samaria. The most minute proportion of lime added to samaria causes the sharp line at $1/\lambda^2$ 269 to vanish, while at the same time it much intensifies the other bands (Tr., pt. ii. 1885; C. R., June 15, 1885). The action of lime upon yttria is of great use in detecting very minute traces of this earth when in admixture with elements which would otherwise prevent its phosphorescence.

Alumina is also active in inducing new spectra when mixed with the rare earths. A moderate amount of fractionation has enabled the writer to penetrate beneath the veil of red phosphorescence observed in crude alumina and to see a complicated sharp-line spectrum (C. N., 56, 62, 72). The new body of which glimpses have been obtained is probably one of the unknown earths in decipia since the new spectrum may be fairly reproduced by adding one of the fractionations of decipia to alumina. Hence, it will be seen that the performance of a long series of check and counter-check experiments often becomes necessary before the presence or the absence of any particular earth can be inferred.

The quantitative separation of the rare metals is much more difficult than their mere recognition. These substances are not linked to one another, or to other elements with which they are associated, by any strong affinities, but they are nearly identical in their behaviour and properties. Hence we have so far been unable to find any reagent or any mode of treatment which at once quantitatively separates one of these substances from all the others. We are therefore obliged to have recourse to tedious processes of fractionation.

In attempting to enumerate or describe the rare metals, we meet with the additional difficulty that the unity character of many of them is still a matter of extreme doubt.

Several of the rare metals will be found described in their proper alphabetical order in this Dictionary, e.g. *beryllium*, *cerium*, *didymium*. Many of these, as will be seen below, are probably capable of being further split up, but as they are frequently mentioned in chemical treatises and memoirs their description as at present, or lately, known has been found necessary.

There are certain other metals which are still under discussion, e.g. *decipium*, *philippium*, *holmium* (Soret's X), and *dysprosium*. Roscoe has indeed proved that *philippium* is a mixture of *terbium* and *yttrium*, and the experiments of the writer have confirmed his results; but until we know more about the constitution of *terbium* and of *yttrium*, both of which are undoubtedly compound bodies, these experiments do not carry us much further. *Samarium* is also identical

with a mixture of two bodies into two parts, just as the addition of a reagent only divides a mixture into two portions, a precipitate and a solution. These divisions will be effected on different lines according to the reagent employed. Thus, if we add ammonia to a mixture we may get a separation into two parts, but if we add oxalic acid to the same original solution we split up the mixture differently and obtain two other parts. Thus, if we crystallise a solution of old *didymium*, as was done by Auer von Welsbach, we divide its components into *neodymium* and *praseodymium*. But by fusing *didymium* nitrate we divide its components in a different way and obtain different products. Now, it is clear that so long as by different modes of attack we obtain different products, we have not yet reduced the original substance to its ultimate elements, we have not yet reached bed-rock.

We find that a compound molecule may behave as an element, as has been shown in the case of old *didymium*. Chemists have a certain

FIG. 1.—Absorption-spectrum of Didymium.

The scale is $\frac{1}{\text{Å}}$.

with a body which other chemists have named 'yttrium β '.

It has been mentioned elsewhere that the old *didymium*, after the elimination of Delafontaine's *decipium*, was found by Lecoq de Boisbaudran to contain another body, which he named *samarium*, characterised by the bands of Delafontaine's *decipium*, together with two additional bands (cf. figs. 1 and 2). After the removal of these bodies the residual *didymium* was split up by Auer von Welsbach into the two bodies, *neodymium* and *praseodymium*, the absorption-spectra of which are shown respectively in figs. 3 and 4. It will be observed, however, that two of the bands of old *didymium* are not to be found in the *neodymium* and *praseodymium* spectra taken conjointly. Hence it becomes extremely probable that there exists a third body distinct from *neodymium* and *praseodymium* to which one of these extra bands, or possibly both, is due. This probable metal the writer has provisionally named Da. But we still encounter the question whether *neodymium*, *praseodymium*, and Da are ultimate elements, or are capable of still further scission. The researches of several investigators point very decidedly in the latter direction. Thus Nilson & Krüss in 1887 appear to have obtained from *didymium* no fewer than nine bodies, each of which may possibly prove to be an element. These bodies have been provisionally named by the discoverers Dia, Di β , Di γ , Di δ , D ϵ , Di η , Di θ , Di ι , and Di κ .

It seems to the writer that *neodymium* and *praseodymium* are simply the products into which the original *didymium* is split up by one particular mode of attack. Any single chemical operation, whether it be crystallisation, precipitation, fusion, partial solution, &c., can only

separate a mixture of two bodies into two parts, regular use, and if a substance resists all these and otherwise behaves as a simple body, they call it an element. But for all this it may prove to be a compound. Hence, we may legitimately pause before conceding to *neodymium* and *praseodymium* the rank of elements. We need some criterion for an element which shall appeal to our reason more clearly than the old untrustworthy characteristic of having not as yet been decomposed; and to this point chemists would do well to turn their most serious attention.

FIG. 2.—Absorption-spectrum of Samarium and Decipium (De Boisbaudran).

In *samarium* the writer, by means of the 'radiant matter' test, has recognised four bodies, named provisionally S β , G α , G γ , and G δ . Very similar observations seem to prove that, like *didymium* and *samarium*, *erbium*, *holmium*, *thulium*, *dysprosium*, &c., are compounds or mixtures of a number of closely allied bodies.

In order to ascertain the existence of supposed new elements chemists have proposed as a test that certain absorption-bands seen in different solutions follow the same variations of intensity. If this is the case we may infer that they are all characteristic of one and the same substance. But if one of the bands dies out while others remain unaltered we may judge that two or more distinct bodies are present.

In erbium the writer has detected two bodies, which he has characterised by their absorption bands $\lambda 550^{\circ}$ and $\lambda 498$. Krüss a. Nilson apply apparently to the same bodies the names *Era* and *ErB*. To obviate all confusion it must be remembered that the name 'erbia' has been given to two bodies which are not identical. The substance which ten years ago was called erbia, and which was then supposed to be the oxide of a simple metal, has been resolved by the investigations of Delafontaine, Marignac, Soret, Nilson, Clève, Brauner, and others into at least six distinct earths. Three of these—scandia, ytterbia, and terbia—give no absorption-spectra, while three others—erbia (new), holmia, and thulia—give absorption-spectra. The first to question the elementary character of old erbium was Delafontaine (*C. R.* 87, 559; *C. N.* 38, 202). He obtained from it and described philippia, a yellow oxide having a strong band in the violet ($\lambda 400$ to 405), a broad black absorption band in the indigo-blue (about $\lambda 450$), two rather fine bands in the green, and one in the red.

The history of philippium is very instructive. Soon after Delafontaine's discovery, Soret (*C. R.* 89, 521; *C. N.* 40, 224) stated that he was unable to identify 'Soret's X' with Delafontaine's philippia, the latter being characterised by an absorption-band in the blue occupying the same place as one of the erbia bands. In 1880 Delafontaine (*C. R.* 90, 221; *C. N.* 41, 72) described ten new earths as present in gadolinite and samarskite, viz., mosandra, philippia, ytterbia, decipia, scandia, holmia, thulia, samaria, and two others to which he did not assign names. He concluded that the properties of philippia were identical with those of Soret's X and of Clève's holmia, and proposed that the name holmia should be set aside in favour of philippia. In *C. R.* 91, 328 (also *C. N.* 42, 185), Clève repeated his earlier assertion that philippia was not identical with Soret's X or holmia. Delafontaine then withdrew all he had said about the absorption-spectrum of philippium and decided that it had no absorption-spectrum at all (*Archives de Genève* [3] 999, 15). Lastly Roscoe (*C. J.* 41, 277) gave an elaborate account of the earth metals in samarskite, proving philippia to be a mixture of yttria and terbia. The present writer, after prolonged chemical examination of these earths, has come to a similar conclusion; but a spectroscopic examination of the earth left on igniting some very carefully-purified crystals of philippium formate, tested in the radiant matter tube, has shown that in the separation of Delafontaine's 'philippium' the yttria undergoes a partial fractionation.

Shortly after the announcement of philippium, Soret (*C. R.* 86, 1062) described an earth which he provisionally named X. It was subsequently found to be identical with Clève's holmia (*C. R.* 89, 479; *C. N.* 40, 125). The absorption-spectrum of this earth is marked by a very strong band in the extreme red ($\lambda 804$), two characteristic bands in the orange and green ($\lambda 640$ and 538), with fainter lines in the more refrangible part of the spectrum, and a number of bands in the ultra violet (see fig. 7). The claim of holmium to rank as an element has been disputed by Nilson and Krüss, who assert that it consists of, or at least contains, four distinct

bodies, provisionally named Xa, Xb, X γ , X δ . By submitting Soret's X to fractional precipitation, and examining the fractions spectroscopically, Lecoq de Boisbaudran found that this X, otherwise holmium, consisted of at least two elements: one of these he has named dysprosium, reserving the name holmium for the residue left after the elimination of the dysprosium. The absorption-spectrum of dysprosium shows four bands, $\lambda 451\frac{1}{2}$, 475, $756\frac{1}{5}$, and $427\frac{1}{5}$. The absorption-spectrum of what may be called new holmium is shown in fig. 8. What relation this new holmium bears to any of the components observed in the original spectrum of holmium by Krüss and Nilson is not as yet determined.

The writer (*Pr.* 40, 502) obtained an earth by repeated fractionation, in which one of the bands ascribed to dysprosium, that namely at $\lambda 451\frac{1}{5}$, was very strong, though the others were absent. As de Boisbaudran regards the bands $\lambda 475$ and $451\frac{1}{5}$ as both belonging to dysprosium, and as the earth obtained gives $\lambda 451\frac{1}{5}$ strong but with scarcely a trace of $\lambda 475$, dysprosium consists of at least two simpler bodies. Krüss and Nilson in fact resolve it into three bodies to which they have given the provisional names X ζ , X ϵ , X η , and de Boisbaudran gives the absorption-spectrum of dysprosium as shown in fig. 9.

Simultaneously with the discovery of holmia, Clève announced the separation of a second earth from erbia, which he called thulia. Its absorption-spectrum consists of a very strong band in the red $\lambda 680$ to 707 , and one in the blue $\lambda 464\frac{1}{5}$ (fig. 10). The ultimate character of thulium is by no means established. Krüss and Nilson resolve it into two bodies, Tm α and Tm β . Nevertheless the atomic weight of thulium has been determined as $170\cdot7$, and the composition Tm $_2$ O $_3$ has been assigned to its oxide, determinations which for the present must be regarded as premature.

Further, it must be mentioned that the spectrum of old erbium has two faint bands, one at $\lambda 550$ and a second broader one at $\lambda 493$ (fig. 11). These bands are not to be found in the spectrum of holmium, thulium, dysprosium, or the new erbium (fig. 12). In a long-continued fractionation of the erbia group of earths, conducted with an ample supply of the old erbia, the writer finds an earth giving these two bands concentrated at one end, the bands becoming stronger, while at the same time two other bands make their appearance. This phenomenon indicates the existence of another earth as yet unknown, belonging to the erbium group.

We next come to the yttrium group, comprising the metals yttrium, terbium, gadolinium, ytterbium, scandium, mosandrium, columbium, and rogerium. Of these yttrium, terbium, ytterbium, and scandium form the subject of distinct articles in this Dictionary.

Columbium and rogerium were discovered in the samarskite of North Carolina by J. Lawrence Smith in 1879, but nothing further has been published concerning them. This columbium is perfectly distinct from an element sometimes called columbium, but better known as tantalum.

Mosandrium was also discovered by J. L. Smith, and has been the subject of a little controversy. Delafontaine pronounced it a mixture

of terbium, yttrium, erbium, didymium, and phosphorium. In November 1878 and in September 1879 Smith reasserted the elementary character of mosandrium. He states that its compounds are of a deep orange colour, that its double potassium sulphate is not easily soluble, and that its equivalent weight is 51.2. No recent and conclusive investigations on this alleged metal have appeared, and its existence must in the meantime be regarded as exceedingly doubtful.

Decipium has been considered as holding an intermediate position between the didymium and the yttrium groups of rare metals, but its elementary character is very questionable. It has not formed the subject of any recent researches. It is said to show a characteristic absorption band about λ 416.

Gadolinium, otherwise known as the Y_a of Marignac, gives no absorption-spectrum. In the writer's investigations its phosphorescence spectrum was found to consist of those of two of the constituents of yttrium, which will be mentioned below.

Yttrium proves to be an exceedingly complex substance. The body to which all chemists would have applied the name yttria as recently as four years ago may be split up into possibly six, but certainly five, bodies, G_a, G_β, G_γ, G_δ, and G_η, two of which, G_β and G_γ, are also met with as the components of gadolinium. Hence it is convenient to speak of the original substance as 'old yttria' and to remember that such is the substance to which everything written concerning yttria prior to 1885 will be found to refer. Fig. 13 shows the simple phosphorescence spectra of the several components into which yttria may be split up by fractionation. If these components are taken in the order of their apparent basicity—the chemical analogue of refrangibility—the lowest of these constituents gives the deep-blue band G_a; then follows a strong citron band, G_β, which increases in sharpness as it becomes more separated from its associates until it may be called a line; then a red band, G_γ; then a crimson band, G_η; and, lastly, very close together a pair of greenish-blue bands, G_δ.

The diagram, fig. 14, shows a series of nineteen phosphorescence spectra obtained from a prolonged examination of 'old yttria.' The central spectrum, J, is approximately that given by crude 'old yttria,' though this differs slightly according to the mineral from which the old yttria is extracted. After a time fractionation splits up the earth J into two earths here marked x and z, giving slightly different spectra. Fractionating x gives x and y, while z on fractionation yields J and L. It must not be thought that there is so great a difference between any two adjacent spectra as is here shown. To make the diagram accurately represent what is actually seen in the laboratory it would be necessary to place between each of these nineteen spectra about 1,000 intermediate spectra. Beginning at the extreme red it will be seen that a strong band at λ 647 ($1/\lambda^2$ 239) is at its maximum intensity from c to x, when it rapidly disappears and is not seen beyond c and x. The component giving this band the writer names provisionally G_γ. The next band in this red λ 639 ($1/\lambda^2$ 245) reaches its maximum at a or even higher, and fades out be-

tween x and z. The band at λ 619 ($1/\lambda^2$ 261) has its maximum between i and o, dying out rapidly below but being more persistent above. It is called G_γ. Then comes an extremely sharp band λ 609 ($1/\lambda^2$ 269) which appears to belong to an earth absent in gadolinite but present in samarskite and a few other minerals. Its greatest brilliancy is between x and x, and on either side it dies rapidly away. For this the writer proposes the name Sc. Then follows a double orange band, and its two components, though very closely united, are probably capable of separation. The maximum brightness of the first component λ 603 ($1/\lambda^2$ 275) extends from o to the top of the figure. The second component λ 597 ($1/\lambda^2$ 280) begins to fade about q, and is at its greatest brilliancy at the highest spectrum shown on the figure. This band occurs almost isolated in a specimen of crude lanthana, and may be provisionally called G_ε. Next follows the citron, or G_β band, λ 574 ($1/\lambda^2$ 305.5) which is the most prominent feature in the spectrum of old yttrium. This band extends with scarcely diminished sharpness from g to s; above g it fades rapidly and disappears above v. Then follows a double green band separable into two components. The first of these, λ 568 ($1/\lambda^2$ 310) is nearly absent in a, reaches a maximum at d, and disappears at x. The second member of this green pair, λ 563 ($1/\lambda^2$ 315) has its maximum at a and extends only to h. The substance producing this pair of bands may be called for the present G_γ. Then follows a pair of bright green bands which so far show no signs of dividing. They begin at b, reach a maximum at e, and continue with scarcely diminished brightness to q. The body giving this double green band is remarkably persistent and may provisionally be called G_β. Next comes a dark interval followed by a broad, hazy, double-blue band, with its centre at λ 482 ($1/\lambda^2$ 430.5); this band appears at f and grows brighter to the last fraction at s. The substance to which it is due is called G_α. Lastly, at λ 456 ($1/\lambda^2$ 481) appears a deep violet band beginning at about q and brightening as we proceed lower down. In some samples of ytterbia, supposed to be pure, this band is intensely brilliant, but it is absent in a specimen received from Nilson and considered by him to be perfectly pure. Hence it is probably due to another new body which may be provisionally named S_γ.

It must be remarked that the writer's fractionations have been carried far beyond the limits shown in the diagram. Fractions above a and below s afford evidence that the process of differentiation has not yet reached its utmost limit.

On the left side of the diagram will be seen chemical symbols attached to some of the spectra. Thus the top spectrum, a, is the one shown by samarium. At v is the spectrum of Marignac's Y_a, or gadolinium. x shows the spectrum of mosandrium, and z that which is generally pronounced to be pure yttrium. A careful study of this diagram will lead the observer to conclude that samarium, gadolinium, mosandrium, and yttrium are not true chemical elements but compounds, or perhaps very intimate mixtures, of certain simpler bodies. For these bodies the name 'meta-elements' is proposed (W. Crookes,

B. A. Birmingham Meeting, *O. N.* 54, 155; be a complex body, and recognises in it three Krüss & Nilson, *B.* 20, 2184 and *O. N.* 54, 71, 85, distinct substances which he names $Z\alpha$, $Z\beta$, and 135, 142, 154, 165, 172; Marignac, *Archives des* 'new yttria' (*C. R.* 103, 627). It is possible

FIG. 14.—Phosphorescence-spectra of components of 'Old Yttria.'

Sciences Physiques, 16, No. 5 and *O. N.* 57; W. Crookes, *Pr.* Feb. 10, 1887). that $Z\alpha$ is $G\beta$, and that $G\beta$ and $Z\beta$ are identical, though de Boisbaudran now regards the latter body as terbium (*C. R.* 102, 395, 902).

De Boisbaudran likewise finds yttrium to

The right of the 'new yttria' to bear this name is in the highest degree questionable. De Boisbaudran assigns to it an atomic weight close upon 89, and states that it has a characteristic spark-spectrum but gives no phosphorescence-spectrum either in the radiant matter tube or by his reversion-process. It evidently cannot be regarded as the old yttrium freed from impurities, since the purest specimens of such yttrium give a phosphorescence-spectrum *in vacuo* of such remarkable intensity that it cannot be due to mere traces of impurities. Ga, Gb, &c., can no more be spoken of as impurities in old yttrium than can neodmium and praseodymium (assuming them to be elementary) be viewed as impurities in old didymium.

Marignac's Y_a is probably a compound. The writer recognises in it two at least of the constituents of yttrium, Gb and Gc.

A. E. Nordenskjöld gives the name oxide of gadolinium (a totally different body from Marignac's Y_a or gadolinium) to the mixture of earths in gadolinite which are precipitated by ammonia and oxalic acid, but not by sulphate of potash. This mixture consists of yttria, erbia, and ytterbia. A very interesting point is that however different the minerals from which it has been obtained, and however the percentage of the rare earths varies, the equivalent weight of the mixture is always approximately the same, viz. 261.9. This value is determined by transforming a weighed quantity of the oxide into sulphate by digestion with dilute sulphuric acid, and driving off excess of water and acid by heating to incipient redness (Nordenskjöld, *C. R.* 102, 795; W. Crookes, *C. N.* 54, 239).

On the other hand, commenting on this, De Marignac shows that there is sometimes a variation of 15 p.c. in the equivalent weights of these natural mixtures of rare earths (De Marignac, *Arch. des Sci. Phys.* 17, No. 5).

We have therefore some thirty bodies of which the so-called rare metals are composed, or, at least, which they contain; and a variety of facts points to the conclusion that we have by no means come to the end. Several even of the new bodies give signs of a capability of further splitting up, if they are examined with sufficient nicety and persistence. It is far from unlikely that when the various methods of research known as fractionation have been more generally applied we may have to deal, not with thirty, but with nearer sixty, unknown bodies.

But whatever may be the number of these bodies the question must be raised, What are they? Are they each and all independent elements? We have certainly no good *a priori* grounds for asserting that the number of elements now recognised is not capable of considerable extension. But before any body can be accepted as simple it should certainly undergo a very severe scrutiny, more severe than any of these newly-discovered bodies has yet undergone. The case of didymium is here a warning. 'It had been closely examined by some of the ablest chemists in Europe, it had been freed from several foreign bodies, its atomic weight had been established, when a novel mode of examination proved its compound nature.'

Pending therefore the completion of a series of investigations, chemical and optical, which

will probably occupy several generations of chemists, it may be safest to call these recently observed bodies not, as yet, elements, but quasi- or meta- elements. Our notions of a chemical element have been enlarged; hitherto the elemental molecule has been regarded as an aggregate of two or more atoms, and no account has been taken of the manner in which these atoms have been agglomerated. The structure of a chemical element is certainly more complicated than has hitherto been supposed. We may reasonably suspect that between the molecules which we are accustomed to deal with in chemical reactions, and the component or ultimate atoms, there may intervene sub-molecules, sub-aggregates of atoms, or meta-elements, differing from each other according to the positions which they occupy in the very complex structures commonly known as didymium, yttrium, and the like.

METAMERISM. This term is generally applied to those cases of *isomerism* wherein compounds show identity of elementary composition, but belong to different types or classes (*v. Isomerism*, pp. 79, 80, 81, 88).

METEORITES. As regards composition, meteorites have been divided into two classes; those which consist for the most part of metals only, and those which are chiefly composed of silicates, sometimes accompanied by unoxidised iron and nickel. Iron and nickel are the principal constituents of those meteorites which are mainly metallic. The quantity of Fe varies from 80 to 95 p.c., and of Ni from 6 to 10 p.c. Co occurs in many meteorites, varying from a mere trace to 2 or 3 p.c.; the other metals found in small quantities are Sn, Mn, Cr, and Cu; small quantities of Fe-Ni phosphide, and also carbide, phosphide, silicide, and sulphide of Fe are also frequently found in metallic meteorites. The silicates which form the chief constituents of meteorites of the second class are silicate of Al, Ca, and Na (*labradorite*), silicate of Ca and Mg (*augite*), and silicate of Fe and Mg (*olivine*). These silicates are often accompanied by nickel and iron, also by iron pyrites, and sometimes by chrome-iron, and magnetic oxide of iron.

M. M. P. M.

METHACRYLIC ACID C₄H₆O₂, *i.e.*

CH₂:CMe.CO₂H. *α*-Methyl-acrylic acid. [16°]. (160.5° i.v.). S.G. ²⁰ 1.0158 (Brühl, *B.* 14, 2800). μ_D -1.4314. R_D -85.07.

Occurrence.—In small quantity in Roman oil of chamomile (Kopp, *A.* 195, 82).

Formation.—1. Obtained as ethyl ether by the action of PCl₅ on oxy-isobutyric ('dimethoxalic') ether CMe₂(OH).CO₂Et (Frankland & Duppa; *C. J.* 18, 133; *A.* 186, 133; Paul, *A.* 188, 52).—2. By the action of fuming HBr on citraconic acid, mesaconic acid, or citraconic anhydride, the resulting bromo-pyrotartaric acid being boiled with conc. NaOH (Fittig, *A.* 188, 95; *B.* 10, 517).—3. By boiling citra- and mesachloro-pyrotartaric acid with alkalis (Prehn, *A.* 188, 42).—4. Together with oxy-isobutyric acid, by boiling α -bromo-isobutyric acid (1 pt.) with water (25 pts.) (Thomson, *A.* 200, 86).

Preparation.—Citraconic anhydride is mixed with a saturated solution of HBr (2 vols.) at 0°. In a few days a mass of crystals of citra-bromo-pyrotartaric acid is got. These are collected,

boiled with Na_2CO_3 , acidified with HCl , and distilled. The distillate is neutralised by CaCO_3 , filtered, evaporated to dryness, and mixed with HCl . Methacrylic acid separates as a light oil (Fittig & C. Kolbe, *J. pr.* [2] 25, 372).

Properties.—Long prisms (from water), with strong but not unpleasant odour. V. sol. water, v. s. sol. alcohol and ether.

Reactions.—1. Bromine forms di-bromo-isobutyric acid.—2. Potash-fusion gives hydrogen, formic acid, and propionic acid (F. A. D.).—3. Sodium-amalgam reduces it to isobutyric acid.—4. Conc. HIAq forms, in the cold, iodo-isobutyric acid crystallising in tufts of prisms.—5. Methacrylic acid dissolves easily in fuming HBr even at 0° , the solution, after some time, depositing a crystalline addition-product and a thick oil (Paul, *B.* 9, 122).—6. Bromine forms $\text{CH}_3\text{Br.CBrMe.CO}_2\text{H}$.—7. On contact with cold conc. HClAq or by heating at 130° , it is converted into an amorphous (? polymeric) modification. The ammoniacal solution of this substance gives white pps. with Ba and Ca salts. It is not altered by conc. H_2SO_4 and HNO_3 (Fittig & Engelhorn, *A.* 200, 70).—8. Hypochlorous acid forms chloro-oxy-isobutyric acid [107°] (c. 235°) (Melikoff, *Bl.* [2] 41, 311).

Salts.— CaA : tufts of long needles, v. sol. water. Appears to change on keeping to a salt of the polymeric acid (v. Reaction 7).— AgA : needles (from boiling water); scarcely affected by light. Suddenly decomposes at 100° .

Constitution.—Inasmuch as the di-bromo-isobutyric acid, formed by the addition of bromine, is converted by boiling water into a bromo-oxy-butyric acid that can be reduced to α -oxy-isobutyric acid, $(\text{CH}_3)_2\text{C}(\text{OH}).\text{CO}_2\text{H}$, it is clear that methacrylic acid is not $\text{CH}_3\text{CHMe.CO}_2\text{H}$ but $\text{CH}_2:\text{CMe.CO}_2\text{H}$.

References.—BROMO- and CHLORO- METHACRYLIC ACIDS.

METHACYL-BROMIDE v. BROMO-ACETONE.

METHÆMOGLOBIN v. HÆMOGLOBIN.

METHAMIDO v. METHYL-AMIDO.

METHANE CH_4 . Marsh gas. Methyl hydride.

Light carburetted hydrogen. Mol. w. 16. (-155° to -160°). (-131°) at 6.7 atmospheres; -73.5° at 56.8 atmospheres (Wroblewsky, *C. R.* 99, 136). S.G. (air = 1): 553 (Regnault, *C. R.* 36, 676). S.G. (liquid) 416 at -164° (Olszewski, *P.* [2] 31, 58). S.H. 593 (R.). $\mu_D = 1.000412$ (Crouillebois, *C. R.* 67, 692). H.F.p. 21,760. H.F.v. 21,170 (Thomson, *Th.*). H.C.p. 213,500 (Berthelot, *A. Ch.* [5] 23, 179). S. 05449 at 0° (Bunsen, *A.* 93, 18). S. (alcohol) 523 at 0° . **Critical temperature:** -78.5° (Wroblewsky); -99.5° (Dewar, *P. M.* [8] 18). **Critical pressure:** 56.8 atmospheres (Wroblewsky).

Occurrence.—The bubbles of gas given off by decaying vegetable matter in stagnant pools consist of marsh gas, CO_2 , and nitrogen. It often escapes into coal mines, where it is known as fire-damp, since it forms an explosive mixture with air. It escapes from the earth in various places, as in Italy, North America, and especially at Baku on the Caspian. It occurs among the products of distillation of wood, peat, coal, and bituminous shale, constituting 35 to 40 p.c. of coal gas. Methane occurs also in the intestinal gases. It occurs also among the products of the passage of ethylene (Norton & Noyes, *Am. S.*

862) and other gases through a red-hot tube. The gaseous product obtained by heating ethylene at 400° contains 86 p.c. methane and 40 p.c. ethane (Day, *Am. S.* 153).

Formation.—1. By the action of potassium-amalgam on CCl_4 in presence of water (Regnault). 2. By passing a mixture of CHCl_3 or CCl_4 and hydrogen through a red-hot tube (Berthelot).—3. By the action of powdered zinc on chloroform dissolved in aqueous alcohol (Sabanejeff, *B.* 9, 1810).—4. By exposing a mixture of CO and hydrogen to the action of electricity in an induction-tube (Brodie, *Pr.* 21, 245).—5. By the action of water on zinc methide (Frankland).—6. By the action of sodium on MeI in presence of ether (Wanklyn & Buckeisen).—7. In small quantity by passing a mixture of CS_2 and H_2S over red-hot copper (Berthelot, *A. Ch.* [3] 68, 69). 8. By heating CS_2 with PH_3I at 130° (Jahn, *B.* 13, 127).—9. Among the products of the dry distillation of barium formate (Berthelot, *J.* 1857, 426).—10. By distilling crystallised sodium acetate (2 pts.) with KOH (2 pts.) and quicklime (3 pts.) (Dumas, *A. Ch.* [2] 73, 92). Von Schlegel (*A.* 226, 140) recommends 1 pt. of sodium acetate and 2 pts. of soda-lime (cf. Schorlemmer, *C. N.* 29, 7).—11. When river-mud is added to a solution of calcium acetate a slow evolution of a mixture of methane (2 vols.) and CO_2 (1 vol.) occurs, calcium carbonate being left. Calcium lactate undergoes a similar fermentation, the gases being evolved in the same proportion (Hoppe-Seyler, *H.* 11, 561).

Preparation.—By the action of the copper-zinc couple on an alcoholic solution of MeI , the escaping gas being well washed by a scrubber containing a further quantity of copper-zinc (Gladstone & Tribe, *C. J.* 45, 154).

Properties.—Colourless gas. V. sl. sol. water. Much less soluble in alcohol than ethane. Its illuminating power is slight (cf. L. T. Wright, *C. J.* 47, 200). May be liquefied by combined cold and pressure (Caillaet, *J.* 1877, 221). Methane is not absorbed by aqueous KOH or by ammoniacal cuprous chloride. When compressed with water below 0° under a pressure of 80 atmospheres it forms a crystalline hydrate, the critical temperature of which is 21.5° (Villard, *C. R.* 106, 1602; 107, 895).

Reactions.—1. When passed through a red-hot tube it is for the most part unaffected, but a little naphthalene is formed. **Electric sparks** partially convert it into carbon, hydrogen, and acetylene (Berthelot, *C. R.* 67, 1188). When passed over a red-hot palladium spiral it is decomposed, if dry, into carbon and hydrogen, and, if moist, into CO and hydrogen (Coquillon, *C. R.* 86, 1197).—2. It is not attacked by sulphuric acid, by nitric acid, by a mixture of hot conc. H_2SO_4 and HNO_3 , by PCl_5 , or by chlorine in the dark.—3. A mixture of chlorine (2 vols.) with methane (1 vol.) when exposed to sunlight presently explodes. The explosion may also be brought about by an electric spark. If the mixture be first diluted with CO_2 , and then exposed to sunlight, quiet chlorination takes place, and if excess of chlorine is present chloroform and CCl_4 are formed. A mixture of methane (1 vol.) and chlorine (1 vol.) exposed to diffused daylight gives methyl chloride. In presence of moisture, chlorine forms HCl , CO_2 , and CO .

4. A mixture of air and methane passed over a red-hot platinum spiral yields formic acid (Coquillon, *C. R.* 77, 444).—5. When mixed with nitric oxide and fired by an electric spark CO₂ and oxygen are among the products (Cooke, *C. N.* 58, 180).

Constitution.—That the four atoms of hydrogen in methane are of equal value may be inferred from the existence of only one set of methyl compounds. The same thing may be shown thus:—

From CHHHI we may obtain, by treatment with KCy, an acetonitrile CHHHCy which we may call 'α.' From this we can obtain CHHH.CO₂H, CHHCl.CO₂H, CHHCy.CO₂H, and 'β' acetonitrile CHHCyH successively. But from CHHCy.CO₂H we can obtain malonic ether CHH(CO₂Et)(CO₂Et), and thence we can get CHCl(CO₂Et)(CO₂Et), CHCy(CO₂H)(CO₂H), and 'γ' acetonitrile CHCyHH successively. The three acetonitriles 'α,' 'β,' and 'γ' are then found to be identical, hence three at least of the atoms of hydrogen in methane are of equal value. The fourth acetonitrile might probably be obtained from CH(CO₂Et)₃ via CCl(CO₂Et)₃, and CCy(CO₂H)₃ (Henry, *C. R.* 104, 1106). Since $\text{CO} < \text{OC} < \text{OEt}$, the product of the action of

$\text{CO} < \text{Cl}$ on isobutyl alcohol, is the same as

$\text{CO} < \text{OEt}$, obtained from $\text{CO} < \text{Cl}$ and

ethyl alcohol, the carbonyl group is united to two atoms of hydrogen of equal value. Now from aldehyde $\text{CO} < \text{H}$ we may obtain

$\text{Cl} > \text{C} < \text{H}$ whence silver propionate forms $\text{C}_2\text{H}_3\text{O}_2 < \text{C} < \text{H}$. But from aldehyde we

may also obtain $\text{C}_2\text{H}_3\text{O}_2 < \text{C} < \text{H}$ whence

silver acetate yields $\text{C}_2\text{H}_3\text{O}_2 < \text{C} < \text{H}$.

These two acetyl-propionyl derivatives of ortho-aldehyde are found to be identical, hence the two atoms of hydrogen in methane which are displaced by oxygen in forming carbonyl are of equal value. It follows that there are two pairs of equivalent atoms of hydrogen in methane (Geuther, *A.* 205, 203; 225, 290). And since Henry has shown that three of the atoms of hydrogen in methane are equivalent, it follows that the fourth is so also.

References.—Tetra-bromo-, Bromo-iodo, Bromo-nitro-, Chloro-iodo-, Chloro-nitro-, and Tetra-iodo-, Methane, Bromoform, Chloroform, Iodoform, and Methyl, Methylene, and Methenyl compounds. In fact, all organic compounds may be regarded as derivatives of Methane (Kekulé).

METHANE CARBOXYLIC ACID IS ACETIC ACID.

Methane dicarboxylic acid is MALONIC ACID.

Methane tricarboxylic acid $\text{C}_2\text{H}_3\text{O}_6$, i.e. $\text{CH}(\text{CO}_2\text{H})_3$. *Formyl tricarboxylic acid. Methenyl tricarboxylic acid.*

Ethyl ether $\text{CH}(\text{CO}_2\text{Et})_3$. [29°]. (258°) at 760 mm. (195°-206°) at 140 mm. S.G. $\frac{1}{4}$ 1.100. From sodium malonic ether, benzene and ClCO_2Et (Conrad a. Guthzeit, *A.* 214, 81; *B.*

12, 1286; cf. Claisen, *B.* 21, 8397, 3567). Colourless oil. V. sol. alcohol or ether. In a freezing mixture, it solidifies to long needles or prisms. According to Michael (*J. pr.* [2] 37, 473) it dissolves readily in dilute NaOH forming $\text{ONa}(\text{CO}_2\text{Et})_3$, which may be crystallised.

Reactions.—1. With aqueous KOH at 100° it forms HOEt, K_2CO_3 , and potassic malonate.—2. Dilute H_2SO_4 and alcoholic NaOH at 0° also form malonic acid, so that a salt of the acid $\text{CH}(\text{CO}_2\text{H})_3$ has not been obtained.—3. Chlorine forms $\text{CCl}(\text{CO}_2\text{Et})_3$ (Conrad, *B.* 14, 618).

Anilide of the di-ethyl ether $\text{CH}(\text{CO}_2\text{Et})_2(\text{CONHPh})$. [124°]. From sodium-malonic ether and an alcoholic solution of phenyl cyanate (Michael, *J. pr.* [2] 35, 452).

Nitride of the di-ethyl ether v. CYANOMALONIC ETHER.

METHANE PHOSPHONIC ACID v. METHYL PHOSPHINE.

METHANE - TRI - QUINOLYL - HYDRO - IODIDE v. QUINOLINE-IODOFORM.

METHANE SELINIC ACID v. SELENIUM ORGANIC COMPOUNDS.

METHANE SULPHINIC ACID CH_3SO_2 , i.e. $\text{CH}_3\text{SO}_2\text{H}$. From ZnMe_2 and SO_2 (Hobson, *A.* 106, 287). The aqueous solution of the acid soon decomposes with deposition of sulphur.— CaA'_2 (dried at 100°): amorphous.— BaA'_2 (dried at 100°): cubes, v. sol. water, insol. alcohol.— MgA'_2 (dried at 100°).— ZnA'_2 : amorphous.

Derivative.—TRI-CHLORO-METHANE SULPHINIC ACID.

Methane di-sulphinic ether v. METHYLENE DIETHYL DISULPHONE.

METHANE SULPHONIC ACID CH_3SO_3 , i.e. $\text{CH}_3\text{SO}_3\text{H}$.

Formation.—1. By the oxidation of di-methyl trisulphide (Cahours, *A. Ch.* [3] 18, 258), or of di-methyl disulphide (Muspratt, *A.* 65, 251).—2. By oxidising methyl sulphocyanide with nitric acid (S.G. 1.25).—3. By treating tri-chloro-methane sulphonic acid with sodium amalgam (Kolbe, *A.* 54, 174).—4. By heating MeI with aqueous K_2SO_4 at 120° (Colman, *A.* 148, 101).

Properties.—Syrup which decomposes above 130°. Potash-fusion forms K_2CO_3 , hydrogen, and K_2SO_4 (Berthelot, *J.* 1869, 336).

Salts.— $\text{NH}_4\text{A}'$: thin trimetric plates (from absolute alcohol).— LiA' (aq).— $(\text{NaA}')_2$, NaI (Colman).— KA' (dried at 100°).— KHA' (dried at 100°).— CaA' . S. 71 at 20° (Nithack, *A.* 218, 284).— SrA' (aq). S. 83 at 22°.— BaA' (aq): v. e. sol. water, insol. alcohol.— MgA' (aq).— PbA' (aq).— CuA' (aq).— AgA' .

Chloride $\text{CH}_3\text{SO}_2\text{Cl}$. (160°) (N.). S.G. 1.51. From the acid and PCl₅ (Carius, *A.* 114, 142). Not attacked by H_2S , by chlorine, or by KCy (McGowan, *J. pr.* [2] 80, 280). Decomposes aqueous ammonia with evolution of nitrogen.

Amide $\text{CH}_3\text{SO}_2\text{NH}_2$. Formed by passing NH_3 into a solution of the chloride in ether. Prisms (from benzene containing alcohol).

Anilide $\text{CH}_3\text{SO}_2\text{NHPh}$. Large plates (from alcohol) (McGowan).

Derivatives v. CHLORO- and CHLORO-BROMO-METHANE SULPHONIC ACID.

"Methane disulphonie acid $\text{CH}_3\text{S}_2\text{O}_6$, i.e. $\text{CH}_3(\text{SO}_3\text{H})_2$. *Methylene disulphonic acid. Methionic acid.*

Formation.—1. A product of the action of

SO₃ on ether (Liebig, *A.* 18, 35; Wetherill, *A.* 66, 122; Strecker, *A.* 100, 199).—2. From Et₂SO₃ and SO₃ (Hübner, *A.* 223, 208).—3. By the action of hot fuming H₂SO₄ on acetonitrile, acetamide, or sulpho-acetic acid (Buckton & Hofmann, *A.* 100, 133; *C. J.* 9, 241).—4. Together with sulpho-acetic acid, by the action of ClSO₃H on acetic acid (Baumstark, *A.* 140, 82).—5. By heating lactic acid with fuming H₂SO₄ (Strecker, *A.* 118, 290).—6. From methylene iodide and K₂SO₃ (Strecker, *A.* 148, 90).—7. By heating chloroform with aqueous K₂SO₃ at 180° (Strecker).—8. From CCl₄, SO₃, K₂ water, and K₂SO₃ at 125° (Rathke, *A.* 161, 152).—9. By oxidising CH₃(SCy)₂ with HNO₃ (Lermontoff, *B.* 7, 1282).

Properties.—Very deliquescent needles. Not attacked by chlorine or by nitric acid.

Salts.—(NH₄)₂A'': trimetric crystals, m. sol. cold water.—K₂A'': needles. S. 7.1 at 22°.—BaA'' 2aq: pearly tables.—PbA'' 2aq: prisms, v. sol. water, insol. alcohol.—CuA'' 5aq.—Ag₂A'': thin plates.

Derivative v. Bromo-methane disulphonic acid.

Methane tri-sulphonic acid CH₃S₃O₆, *i.e.* CH(SO₃H)₃. Obtained by heating CH₃OSO₃K (1 pt.) with fuming H₂SO₄ at 100° (Theilkuhl, *A.* 147, 134). Formed also by the action of aqueous K₂SO₃ at 100° on CH₃C(NO₂)(SO₃K), or on CCl₃(NO₂) (Rathke, *A.* 167, 219). Long needles; v. e. sol. water and alcohol.—K₂A'' aq: small prisms.—Ca₂A''' 12aq: small prisms, v. sol. water, insol. alcohol.—Ba₃A''' 9aq: plates. Not decomposed by HCl.—Pb₃A''' 9O₃.

METHANE THIOSULPHONIC ACID.
Methyl ether C₂H₅S₂O₂, *i.e.* CH₃SO₂SC₂H₅. *Dimethyl disulphoxide*. Obtained by warming dimethyl disulphide with nitric acid (S.G. 1.2) diluted with four times its volume of water (Lukashevitch, *Z.* 1868, 641). Oil. Readily oxidised by HNO₃ to methane sulphonic acid.

METHANTHRENE C₉H₈. [117°]. An isomeride of methyl-naphthalene obtained, together with other products, by distilling podocarpic acid with zinc-dust (Oudemans, *B.* 6, 1125). The product is crystallised from alcohol and sublimed. White laminae with violet fluorescence. It boils above 360°. V. e. sol. boiling alcohol, OS₂, and HOAc.

Picric acid compound C₉H₅C₆H₃(NO₂)₃OH. [117°]. Slender orange needles.

Methanthrene-quinone C₉H₄O₂. [187°]. From methanthrene and CrO₃ in HOAc. Minute trimetric laminae. May be distilled. Insol. water, sl. sol. ether, v. sol. alcohol. Reduced to a hydride by aqueous SO₂.

METHAZONIC ACID C₉H₇N₃O₃, *i.e.* NO₂CH₂NO₂? [c. 60°]. The sodium salt is formed by acting on nitro-methane with alcoholic NaOH, the resulting crystalline pulp being heated on the water-bath. The upper (alcoholic) layer is poured off, and the lower layer deposits sodium methazonate on cooling. It is dissolved in water and reprecip. by alcohol (Friese, *B.* 9, 304). According to Lecco (*B.* 9, 705) it is best to add dilute H₂SO₄ and shake with ether. If the ether is dried with Na₂SO₄ and evaporated over H₂SO₄, it leaves methazonic acid as large crystals, which may be recrystallised from benzene. It is v. sol.

water, alcohol, and ether, m. sol. benzene, insol. petroleum-naphtha. The Na salt crystallises from alcohol in long prisms.

METHENYL-AMIDINE v. FORMAMIDINE.

METHENYL-AMIDOXIM v. FORMAMIDOXIM.

METHENYL-AMIDO-*o*-CRESOL C₇H₇NO *i.e.*

C₆H₄(CH₃)<N>CH [3:1] [393]. (200°). Colourless crystals. Prepared by the action of formic acid on amido-*o*-cresol (Hofmann & Miller, *B.* 14, 570).

*Methenyl-amido-*p*-cresol* C₇H₇NO *i.e.*

C₆H₄(CH₃)<N>CH [5:1] [46°]. Formed from amido-*p*-cresol by distillation with formic acid (H. & M.). Crystals.

METHENYL-(*a*)-AMIDO-NAPHTHYL-MER-

CAPTAN C₁₀H₇<N>CH. [46°]. Formed by heating formyl-(*a*)-naphthylamine with sulphur. Colourless oily fluid. Insol. water. Volatile with steam. Base.—B'H₂Cl.PtCl₄: yellow needles (Hofmann, *B.* 20, 1799, 2265).

METHENYL-AMIDO-PHENOL C₆H₅NO *i.e.*

C₆H₄<N>CH. [30-5°]. (182-5°). V.D. (H-1) 112.5 (calc. 119). Obtained by boiling formic acid with *o*-amido-phenol (Ladenburg, *B.* 10, 1123). Prisms. Hot conc. HCl aq decomposes it, forming *o*-amido-phenol.

METHENYL-AMIDO-PHENYL MERCAP-

TAN C₆H₅NS *i.e.* [1:2]C₆H₄<N>CH (230°).

Colourless fluid. Sparingly soluble in water, easily in alcohol and CS₂. Has decided basic properties. Heavier than water. Volatile with steam. Isomeric with phenyl mustard-oil.

Preparation.—1. By reduction of the chloro-derivative (vol. ii. p. 78) with tin and HCl or with HI.—2. By the action of formic acid on amido-phenyl mercaptan (Hofmann, *B.* 13, 14). 3. Formed together with aniline, methyl-aniline, and a base C₆H₅NS, by boiling di-methyl-aniline with sulphur (Möhlau & Krohn, *B.* 21, 59f).

Properties.—Oil, smelling like quinoline and having a bitter taste. It is related to thiazole as quinoline is to pyridine. The sulphur cannot be displaced by the action of lead hydrate or even by heating with copper to 250°. On fusion with KOH it gives formic acid and amido-phenyl-mercaptan. PCI₃ at 180° forms the chloro-derivative C₆H₄(NS)CCl.

Salts.—(B'HCl).PtCl₄: sparingly soluble tables, or needles.—(B'HCl)AuCl₃.—B'H₂FeCl₃. *Methylo-iodide* C₆H₅NSMeI: [210°]; needles, sl. sol. cold alcohol, v. sol. hot water.

General character.—This base stands in the same relation to quinoline as thiophene stands to benzene. In consequence of this analogy the base and its derivatives exhibit great similarity in properties with the corresponding quinoline compounds: thus the boiling-points of the methenyl- and ethenyl-*o*-amido-phenyl-mercaptan do not differ much from those of quinoline and methyl-quinoline, and they form crystalline picrates and uncrystallisable chromates. They also form colouring-matters analogous to the cyanines (obtained by the action of alkalis upon a mixture of the alkylo-iodides of quinoline and methyl-quinoline). Thus by boiling an aqueous solution of the amylo-iodides of methenyl- and

ethenyl-amido-phenyl-mercaptans with NH_2 , a red colouring-matter $\text{C}_{10}\text{H}_7\text{N}_2\text{S}_2\text{I}$ is obtained which crystallises in four-sided violet-red plates with green reflex, sol. hot alcohol, sl. sol. cold alcohol, insol. water. Neither of the amylo-iodides when treated separately, in the same way, gives any colouring-matter. In a similar manner to the amylo-iodides, the mixed methyl-iodides give a compound crystallising in reddish-golden plates, sol. alcohol with a scarlet-red colour. Similar colouring-matters are also obtained from the corresponding derivatives of amido-naphthyl mercaptan, or from the latter derivatives conjointly with those of amido-phenyl-mercaptan, or from those of amido-phenyl-mercaptan conjointly with those of quinoline and methyl-quinoline. All the above products are stronger colouring-matters than the cyanines (Hofmann, B. 20, 2262).

Derivatives v. AMIDO-, CHLORO-, and NITRO-METHENYL-AMIDO-PHENYL-MERCAPTAN.

METHENYL-*o*-AMIDO-PHENYL-MERCAPTAN
TAN *o*-CARBOXYLIC ACID $\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}_6\text{H}_4\text{CO}_2\text{H}$ [108°].

Formation.—1. By the action of cold alcoholic caustic potash upon amido-imido-ethenyl-*o*-amido-phenyl-mercaptan

$\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}_6\text{H}_4(\text{NH})_2\text{NH}$, ammonia being eliminated.—2. In small quantity by oxidation of ethenyl-*o*-amido-phenyl mercaptan

$\text{C}_6\text{H}_4\langle\text{N}\rangle\text{C}_6\text{H}_4\text{CH}_2$, with cold aqueous KMnO_4 .

Properties.—White needles. Sol. water and alcohol. It very readily splits off CO , giving methenyl-amido-phenyl mercaptan (Hofmann, B. 20, 2256).

METHENYL-AMIDO-TOLYL MERCAPTAN

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{N}\rangle\text{CH}$ [1:4]. [15°]. (255°). Prepared by boiling *p*-amido-*m*-tolyl-mercaptan with formic acid (Hess, B. 14, 492). Sol. alcohol and ether. Weak base forming unstable salts.—($\text{B}'\text{HCl}$), PtCl_4 ; needles.

METHENYL-AMIDOXIM v. FORMAMIDOXIM.
METHENYL-AMIDO-XYLYL MERCAPTAN

$\text{C}_6\text{H}_4(\text{CH}_3)_2\langle\text{N}\rangle\text{CH}$. From the thio-formyl derivative of *u-m*-xylylidine $\text{C}_6\text{H}_4\text{Me}_2(\text{NH.CSH})$ by oxidising with alkaline K_2FeCy , (Gudeman, B. 21, 2549). Heavy oil.

METHENYL-BROMO-TOLYLENE-*o*-DIAMINE. [1:4:2] $\text{C}_6\text{H}_4(\text{CH}_3)(\text{Br})\langle\text{NH}\rangle\text{CH}$.

[187°]. Obtained by heating bromo-tolylene-diamine with formic acid (Hübner a. Schüpphaus, B. 17, 776). Fine colourless needles. Sol. alcohol, ether, and acetone, sl. sol. water and benzene.

Salts.— $\text{B}'\text{HCl}$: colourless soluble needles.— $\text{B}'\text{H}_2\text{SO}_4$: long needles.— $\text{B}'\text{HNO}_3$: sparingly soluble colourless needles.— $\text{B}'\text{H}_2\text{Cl}_2\text{HgCl}_2$: needles.— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_4$: orange crystalline pp.— $\text{B}'\text{H}_2\text{CrO}_4$: glistening red needles.— $\text{B}'\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$: this picrate forms yellow needles (229°).

METHENYL-TRICARBOXYLIC ACID v. METHANE-TRICARBOXYLIC ACID.

METHENYL FLUORIDE CHF_3 . *Fluoriform*. V.D. 2.50 (calc. 2.44). S. (alcohol) 5.

Formed by warming a mixture of iodoform (3 pts.), chloroform (1 pt.), and silver fluoride (2 pts.) (Mealans, C. R. 110, 717). Colourless gas, condensing at 20° under 40 atmospheres' pressure. Smells like chloroform, and burns with blue flame forming HF . Sl. sol. water, chloroform, and benzene. Alcoholic KOH yields KF and potassium formate.

METHENYL DI-PHENYL-DIAMINE v. DI-PHENYL-FORMAMIDINE.

METHENYL-*o*-PHENYLENE-DIAMINE

$\text{C}_6\text{H}_4\langle\text{NH}\rangle\text{CH}$. *Anhydro-formyl-phenylene diamine*. [167°]. (above 360°). Prepared by heating *ortho*-phenylene diamine for 5 or 6 hrs. with formic acid. The yield is nearly theoretical (Wundt, B. 11, 826). Large crystals. Monacidic base.—($\text{B}'\text{HCl}$), PtCl_4 .—($\text{B}'\text{HCl}$) AuCl_3 .

METHENYL TRI-PHENYL TRI-KETONE

v. TRI-BENZOYL-LETHANE.

METHENYL-DI-TOLYL-AMIDINE v. DI-TOLYL-FORMAMIDINE.

METHENYL-TOLYLENE-*o*-DIAMINE

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{NH}\rangle\text{CH}$ [1:2:3]. [143°]. Obtained by reduction of methenyl-bromo-tolylene-*o*-diamine (Hübner a. Schüpphaus, B. 17, 777). Colourless glistening needles (from benzene). V. e. sol. water and alcohol.

Salts.— $\text{B}'\text{HNO}_3$: long soluble needles.— $\text{B}'\text{H}_2\text{Cl}_2\text{PtCl}_4$ 8aq: sparingly soluble orange needles.

Methenyl-tolylene-diamine

$\text{C}_6\text{H}_4(\text{CH}_3)\langle\text{NH}\rangle\text{CH}$ [1:3:4]. [a. 101°]. From the diamine and formic acid (Ladenburg, B. 10, 1123).— $\text{B}'\text{H}_2\text{PtCl}_4$: yellow prisms.

METHIONIC ACID v. METHANE DISULPHONIC ACID.

METHOXY-compounds v. Methyl derivatives of Oxy-compounds.

METHRONIC ACID $\text{C}_6\text{H}_5\text{O}_3$, i.e. $\text{C}_6\text{H}_5\text{O}(\text{CO}_2\text{H})_2$, $\text{C}(\text{CO}_2\text{H})_3$.

or OMe . O . $\text{C.CH}_2\text{CO}_2\text{H}$ (Knorr, B. 22, 152).

Di-methyl-furfurane dicarboxylic acid. Sylvane carboxyacetic acid. Pyrotrikaric carboxylic acid. [205°] (F.); [207°] (P.).

Formation.—1. By heating equimolecular weights of aceto-acetic ether, Ac_2O , and sodium succinate, and saponifying the resulting monoethyl methronate $\text{C}_6\text{H}_5\text{O}(\text{CO}_2\text{Et})(\text{CO}_2\text{H})$ with baryta (Fittig, A. 250, 173, 182).—2. By treating a mixture of glyoxal and aceto-acetic ether with a concentrated aqueous solution of ZnCl_2 , and extracting the product with aqueous KOH (Polonowsky, A. 246, 6; Fittig a. Hantzsch, B. 21, 2135, 8189).

Properties.—Needles (from water); v. e. sol. alcohol, m. sol. ether and HOAc, m. sol. hot, v. sl. sol. cold, water, almost insol. CHCl_3 and CS_2 . The aqueous solution gives no colour with FeCl_3 . It is not attacked by reducing agents.

Reactions.—1. On heating it gives off carbonic acid gas leaving methyl-furfuryl-acetic

acid $\text{CH}=\text{CH}$ [189°].—2. Dilute

OMe . $\text{O.C.CH}_2\text{CO}_2\text{H}$ HClAq at 200° gives CO , and acetonyl-acetone.

Salts.—(NH_4) A^+ 8aq: small needles.— CaH_2A^+ : heavy crystalline pp. nearly insol.

hot water.—CaA" 2aq.—BaA" 2aq: needles (P.).—BaA": amorphous (F.).—BaH₂A": needles, more soluble than the Ca salt (F.).—Ag₂A"aq: bulky white pp.

Mono-methyl ether MeHA": [98°]; needles.—AgMeA": white pp. (P.).

Di-methyl ether Me₂A". Oil.

Mono-ethyl ether EtHA". [76°]. Prepared as above. Long pointed needles, v. sol. alcohol, ether, chloroform, and benzene; m. sol. CS₂; sl. sol. water.—Ca(EtA")₂ 2aq: needles or prisms.—Ba(EtA")₂ 2aq: needles, v. sol. hot, sl. sol. cold, water.—AgEtA": white matted needles.

Di-ethyl ether Et₂A". (300°–305°) (F.).

Phenyl hydrazide C₆H₅N₂O₂, i.e.

C₆H₅O₂N₂HC₆H₅. [212°] (F.).

Phenyl hydrazide of the mono-ethyl ether C₆H₅N₂O₄: [184°]; crystalline. Insol. cold aqueous alkalis.

METHRONOL C₆H₁₂, i.e.

CH:CH.C.CHPh.CHMe

CH:CH.O.CH₂.CHMe ? *Phenyl-di-methyl-*

naphthalene tetrahydride. (823°). V.D. 8.0

(calc. 8.2). Formed from phenyl-methacrylic acid by heating with H₂SO₄ (40 c.c.) and water (60 c.c.) (H. Erdmann, A. 227, 250). Oil. Chromic mixture oxidises it to o-benzoyl-benzoic acid, acetic acid, benzoic acid, anthraquinone, and CO₂.

METHYL. The radicle CH₃. The name methyl was also given by Frankland and Kolbe (C. J. 1, 60) to dimethyl C₂H₆, now called ethane. The methyl derivatives of hydroxylic compounds are described under the compounds of which they are the ethers: e.g. CH₃O.C₂H₅.CO₂H, the methyl derivative of oxy-benzoic acid is described under OXY-BENZOIC ACID.

DI-METHYL-ACETAL so-called. V. vol. i. p. 105.

METHYL-ACETAMIDE v. *Acetyl derivative of METHYLAMINE*.

METHYL-ACETANILIDE v. *Acetyl derivative of METHYL-ANILINE*.

METHYL-ACETATE v. *ACETIC ACID*.

METHYL-ACETIC ACID is *PROPIONIC ACID*.

Di-methyl-acetic acid is *ISO-BUTYRIC ACID*.

Tri-methyl-acetic acid v. *VALERIC ACID*.

METHYL-ACETO-ACETIC ACID v. vol. i. p. 22; vol. ii. p. 78.

METHYL ACETO-ACETATE v. *ACETO-ACETIC ACID*.

METHYL-DI-ACETONAMINE v. *ACETON-AMINE*.

METHYL-ACETONE v. *METHYL ETHYL KETONE*.

Di-methyl-acetone v. *METHYL ISOPROPYL KETONE* and *DI-ETHYL KETONE*.

METHYL-TRI-ACETONE-ALCAMINE v. *ACETONE-ALCAMINE*.

METHYL-TRI-ACETONINE v. *ACETONINES*.

METHYL-ACETO-PROPIONIC ACID v. *ACETYL-BUTYRIC ACID*.

METHYL ACETO-SUCCINIC ETHER v. *ACETYL-METHYL-SUCCINIC ETHER*.

METHYL-ACETOETHENONE v. *METHYL-THIENYL METHYL KETONE*.

METHYL-ACETYL-BENZENE v. *TOLYL METHYL KETONE*.

Di-methyl-acetyl-benzene v. *XYLYL METHYL KETONE*.

METHYL-ACETYLENE v. *ALLYLENE*.

Di-methyl-acetylene v. *BUTYNE*.

Di-methyl-di-acetylene C₆H₂, i.e.

CH₂.C₂C₂CH₂. *Hexyne*. [64°]. (180°). Formed by oxidising the copper derivative of allylene with alkaline K₂FeCy₄ (Griner, C. R. 105, 283). Solid; volatile with steam. Does not react with ammoniacal cuprous chloride. Combines with bromine in the cold, forming C₆H₂Br₄ [44°].

METHYL-ACETYLENE-DI-QUINOLINE

C₂₁H₁₆N₂, i.e.

C₆H₄ < CH:CH CH:CH.O.N:OMe
N:C.CH:CH.O : CH.O.CH:CH . *Ethyl-ene-quinoline-methyl-quinoline*. [157-5°]. Formed on heating p-amido-(Py. 3)-styryl-quinoline with HCl at 150°, and then gradually adding paraldehyde (Bulach, B. 22, 289).

DI-ν-METHYL-ACETYLENE-DI-UREA

C₆H₁₀N₂O₂, i.e. CO < NMe.CH.NMe
NH.CH.NH > CO or

CO < NMe.CH.NH
NH.CH.NMe > CO. *Glycol-di-methyl-uril*.

[210°]. Formed by adding HCl to a mixture of glyoxal and methyl-urea (Franchimont a. Klobbie, R. T. C. 7, 19). Needles, v. sol. water; insol. ether and ligroin. Forms with HNO₃ a di-nitro-compound, which is not decomposed by boiling with water.

Di-methyl-acetylene-di-urea C₆H₁₀N₂O₂, i.e.

CO < NH.CMe.NH
NH.CMe.NH > CO. Formed by heating di-

methyl-diketone with urea in aqueous solution (Franchimont a. Klobbie, R. T. C. 7, 251). Prisms or needles; insol. ether and CHCl₃, sl. sol. alcohol. Does not melt below 290°. Nitric acid converts it into a nitramine

CO < NH.CMe.N(NO₂)
NH.CMe.N(NO₂) > CO, which crystallises

from alcohol in plates, and is decomposed by boiling water into CO₂, N₂O, di-methyl-diketone, and urea.

α-DI-METHYL-β-ACETYL-PROPIONIC ACID v. *MESITONIC ACID*.

METHYL-ACETYL-PYRROLE v. *METHYL-PYRRYL METHYL KETONE*.

ν-Methyl-di-acetyl-pyrrole v. *METHYL-PYRRYL-ENE DI-METHYL-DI-KETONE*.

METHYL-ACETYL-UREA v. *Acetyl derivative of METHYL-UREA*.

METHYL-ACRIDINE C₁₁H₉N, i.e.

C₆H₄ < CMe
N > C₆H₅. [114°]. Formed by heating

diphenylamine (50 g.), glacial acetic acid (30 c.c.), and ZnCl₂ (85 g.) at 220° for 14 hours. The yield is good (32 g.) (Bernthsen, A. 224, 35). Formed also by heating diphenylamine with acetonitrile at 300° (Bernthsen, A. 192, 29). Dimetric crystals; a:c = 1:2397 (Bernthsen a. Osann, B. 19, 427). Aqueous KMnO₄ at 100° oxidises it very slowly, a product being perhaps quinoline tri-carboxylic acid. HNO₃ (S.G. 1.88) boiled for 6 hours with methyl-acridine (6 g.) gives tri-nitro-acridine carboxylic acid, which forms glittering

prisms, sparingly soluble in the usual menstrua. —B'HOI.—B', H₂PO₄.

Methylo-iodide B'MeI: [185°]; red needles (from water). Sol. hot water, less sol. hot alcohol, least sol. ether.

Methylo-chloride B'MeCl. Decomposes at 180°–135°.

Methylo-hydroxide B'Me(OH). From the methylo-iodide by treatment with aqueous NaOH. Gray powder, turning green in air. Sol. alcohol, but soon decomposes.

[132°]. Formed by distilling diamido-di-*p*-tolyl-phenyl-methane PhCH(C₆H₄MeNH₂), with zinc-dust (Ullmann, *J. pr.* [2] 36, 265). Yellow matted needles. Smells aromatic, and causes sneezing. V. al. sol. water, v. sol. alcohol, ether, benzene, and hot petroleum-ether. Its solution in dilute H₂SO₄ exhibits bluish-green fluorescence.

Di-methyl-acridine C₁₄H₁₂N 2e.

by heating phenyl-*p*-toluidine (12 g.) with HOAc (6.6 g.) and ZnCl₂ (18 g.) at 230° (Bonna, *A.* 239, 64). Needles or prisms (from alcohol). Volatile with steam. V. sol. alcohol and benzene.—B'HOI: yellow needles.—B'HI: orange-red needles.—B'C₆H₅(NO₂)OH: brown crystals.—The sulphate is reddish-brown.

Methyl-acridine chloral v. Tri-chloro-oxypropyl-acridine.

DI-METHYL-ACRYLIC ACID v. PENTENOIC ACID.

TETRA-METHYL-ADIPIC ACID C₁₄H₂₀O₄, i.e. CO₂H.OH.CMe₂.CMe₂.CH₂.CO₂H? [210°]. A product of the action of finely-divided silver on α-bromo-isovaleric ether CHMe₂.CHBr.CO₂Et (C. Hell a. W. Mayer, *B.* 22, 52). Snowy-white granules (from benzene); v. sol. alcohol and chloroform. Forms no anhydride on heating (difference from di-isopropyl-succinic acid which accompanies it in its preparation). May be sublimed.—BaA" 3aq. —SrA" 4aq. S. 16.6 at 19°.—MgA" 8aq. S. 12.5 at 15°.—MnA" 3aq. S. 5.9 at 35°.—NiA" 4aq. S. (of NiA") 4.7 at 25°.—CoA" 8aq. S. (of CoA") 6.65 at 23°.—ZnA" S. 19.5 at 18°.—CdA" 8aq. S. 2.29 at 81°.—CuA" S. 0.24.—PbA" S. 0.45 at 13°.—AgA" S. 0.46 at 18°.

METHYL-ESCULETIN v. ESCULETIN.

METHYLAL v. FORMIC ALDEHYDE.

METHYLALACREATINE v. ALACREATINE.

METHYL ALCOHOL CH₃O i.e. CH₃.OH. *Oxy-methane. Methylo-hydroxide. Wood spirit. Wood naphtha.* Mol. w. 32. (64.8°) (R. Schiff, *A.* 220, 99); (65.9°) (Perkin, *C. J.* 45, 465); (66.2°) (Zander). S.G.²⁰ 7953 (Brühl); 79726; 78941 (Perkin); 8111 (Zander). S.V. 42.7 (S.); 42.6 (Lössen, *A.* 254, 55). $\mu_D = 1.3332$. $n_D = 1.298$ (Brühl). H.F.p. 51.450 (Thomsen); 51.400 (Stohmann, *J. pr.* [2] 40, 358). H.F.v. 50.580 (Thomsen, *Th.*), H.C. 170.600 (Stohmann). M.M. 1.640 at 18.7°. *Compressibility*: 0.0010879 at 15° (Dupré, *Pr.* 20, 336).

Occurrence.—Free in the juices of plants (Guthzeit, *J.* 1879, 905; Maquenne, *C. R.* 101, 1067) and in the aqueous distillate in the fruits of *Heracleum* (Guthzeit, *A.* 177, 344; 240, 248).

Methyl alcohol occurs also in the product of the distillation of wood (Taylor [A.D. 1812], *Tylock's Phil. Mag.* 60, 815; Dumas a. Peligot, *A.* 15, 1; *A. Ch.* 58, 5; 61, 193) and of colophony (Kebbe a. Lwow, *B.* 16, 351). It occurs as methyl salicylate in oil of winter-green (*Gautheria procumbens*).

Formation.—1. From methane by chlorinating, and heating the resulting methyl chloride with aqueous KOH for 7 days at 100° (Berthelot, *A.* 105, 241). The MeCl may also be treated with HOAc and NaOAc at 200°, and the resulting MeOAc saponified. MeCl treated with Ag₂SO₄ and H₂SO₄ at 100° gives HMeSO₄, whence methyl alcohol can be readily obtained.—2. From hydrogen cyanide by reduction with zinc and H₂SO₄, and treating the resulting methylamine with nitrous acid (Linnemann, *Z.* [2] 4, 284).—3. By distilling calcium formate (Lieben a. Paternò, *G.* 3, 290; *A.* 187, 293; Friedel a. Silva, *C. R.* 76, 1545).

Preparation.—The crude watery liquid obtained by the distillation of wood contains methyl alcohol, acetone, acetic acid, methyl acetate, and ammonium acetate. It is separated from the tarry products and redistilled; the first tenth of the distillate is mixed with slaked lime and redistilled; a little sulphuric acid is then added, and the liquid redistilled and rectified over quicklime. The crude wood spirit thus obtained has a strong aromatic odour and turns brown on keeping. It contains methyl acetate, acetone, di-methyl acetic orthaldehyde CH₃.CH(OMe)₂ (Daneer, *C. J.* 17, 222), allyl alcohol, methyl ethyl ketone, and other ketones (Grodzky a. Krämer, *B.* 9, 1920). Methyl alcohol may be obtained from wood spirit by saturating with fused CaCl₂ and heating on a water-bath. The residue is a compound of methyl alcohol with CaCl₂, which when distilled with water is decomposed, giving off the methyl alcohol. The distillate is then rectified over quicklime (Kane, *A.* 19, 164). According to Gould (*C. J.* 7, 811) it is best to distil the wood spirit with conc. NaOHAq (to saponify MeOAc) and then to dehydrate with K₂CO₃ before saturating with CaCl₂. A better method for obtaining methyl alcohol from wood spirit is to distil the spirit (1 pt.) with H₂SO₄ (1 pt.) and potassium oxalate (2 pts.); the crystalline di-methyl oxalate is then decomposed by distillation with water, and the MeOH dried over lime (Wöhler, *A.* 81, 376). The oxalate may also be obtained by dissolving oxalic acid, dehydrated at 100°, in boiling MeOH, leaving the solution to cool, and washing the crystals with cold water as long as the filtrate exhibits the iodoform reaction (Erlenmeyer, *N. Rep. Pharm.* 23, 624). An alternative method consists in passing HCl into a solution of benzoic acid in wood spirit, distilling, ppg. with water the portion collected above 100°, decomposing by boiling for several hours with aqueous NaOH, distilling, and rectifying over quicklime (Caripa, *A.* 110, 210). The following modification of Wöhler's process is recommended by Dittmar a. Fawcitt (*Tr. E.* 38, 509): 100 c.c. of wood spirit are digested with 150 g. of powdered NaOH, and then distilled on a water-bath; 500 g. of oxalic acid crystals are mixed with 200 c.c. of sulphuric acid, and then 400 c.c. of the alcohol, purified as above, is added, and the whole cautiously heated on a

water-bath. The methyl oxalate thus obtained is thoroughly dried by pressure, and the alcohol regenerated by digestion with water at 70°. To dehydrate the alcohol thus obtained, digestion with baryta, lime, and dried copper sulphate is necessary. Even when prepared from the oxalate methyl alcohol is not quite pure, as it contains bodies which exhibit Lieben's iodoform reaction. It may be freed from these by dissolving in it one-tenth of its weight of iodine, gradually adding NaOH until the liquid is distinctly alkaline, and distilling. The product, rectified over CaO, has a specific gravity of .81 at 15° (Regnault a. Villejean, *A. Ch.* [6] 4, 430; *C. R.* 99, 82). Methyl alcohol may also be prepared by saponifying methyl formate (β pts.) with NaOH (2 pts.) and water (6 pts.) (Grodski a. Krämer, *B. 9*, 1928; Barty a. Bordet, *A. Ch.* [5] 16, 564). Methyl alcohol may be obtained very nearly pure by distilling oil of winter-green with potash, and rectifying the distillate over lime.

Properties.—Colourless mobile liquid, with purely spirituous odour. Burns with a pale flame. Mixes with water, alcohol, and ether; dissolves fixed and volatile oils and most resins. Hence it is much used as a solvent. In aqueous solution it produces intoxication, in concentrated solution it is poisonous. When perfectly dry it dissolves a little CuSO₄, acquiring a bluish-green colour; but it does not dissolve crystallised CuSO₄.7aq (Klepl, *J. pr.* [2] 25, 526). Methyl alcohol is etherified by acetic acid more rapidly and completely than any other alcohol (Menschutkin, *Z. P. C. I.* 611). Dittmar a. Fawsitt give the specific gravity of mixtures of methyl alcohol and water as follows:

P.c. of CH ₃ .OH	S.G. at 0°	S.G. at 15.96°
0	.99987	.99907
10	.98429	.98262
20	.97233	.96808
30	.96057	.95367
40	.9457	.93697
50	.92873	.91855
60	.90917	.89798
70	.88687	.87487
80	.86314	.85035
90	.83751	.82396
100	.81015	.79589

Older determinations are by Ure (*P. M.* [3] 19, 51), Dupré (*Pr.* 20, 336), and Duclaux (*A. Ch.* [5] 13, 87). The same observers find the vapour tension of methyl alcohol, measured in millimetres of mercury at 0°, to be:

Temp.	Tension	Temp.	Tension
0	29.7	40	259.4
10	58.8	50	403.4
20	94.0	60	624.3
30	158.9	64.96	760.0

(cf. Kononoff, *P.* [2] 14, 40). The following vapour-tensions are given by Richardson (*C. J.* 49, 762):

Temp.	Tension.	Temp.	Tension
-8.3	17.3	33.2	235.13
+0.7	32.06	49.2	370.26
11.2	55.82	59.9	584.24
22.7	108.96	65.7	753.05
30.2	155.32		

VOL. III.

The specific heat of aqueous methyl alcohol was found by Dupré to be as follows:—

Weight p.c. of methyl alcohol	Specific heat	Weight p.c. of methyl alcohol	Specific heat
10	.98582	60	.80177
20	.95914	70	.75500
30	.92658	80	.69999
40	.89219	90	.64282
50	.84645	100	.54325

Estimation.—Pure methyl alcohol does not give Lieben's iodoform reaction with iodine and potash.

The amount of methyl alcohol in commercial wood spirit may be estimated by adding 5 c.c. of the spirit, drop by drop, to 30 g. of PI₂ in a flask provided with inverted condenser. The flask is then heated for 5 minutes in boiling water, and the MeI then distilled off by inclining the condenser. The volume of MeI is read off in a graduated receiver 5 c.c. of methyl alcohol yield 7.19 c.c. of methyl iodide (Krell, *B.* 6, 1310; cf. Grodzky a. Krämer, *B.* 7, 1495; 9, 1928). If it is desired to determine how much of the methyl alcohol is in the form of MeOAc, the spirit may be boiled with standard alkali, and the amount used up in the saponification determined.

Barty and Bordet (*A. Ch.* [5] 16, 565) modify Krell's process, using only 15 g. of PI₂ to 5 c.c. of wood spirit, but adding 5 c.c. of aqueous HI subsequently. They distil the liquid at 80°-90°, and at the end of the distillation add 5 c.c. of water and quickly distil. The methyl iodide is washed once or twice with water and measured.

Di-methyl ortho-acetic aldehyde or methyl-acetal CH₃.CH(OMe)₂ boils at 64° and gives MeI on treatment with PI₂, but it does not react with aniline, so that when the wood-spirit is to be used in preparing di-methyl-aniline, by heating with aniline hydrochloride, the estimation by PI₂ will give too high results.

The presence of acetone is objectionable in methyl alcohol that is to be used for preparing di-methyl-aniline. Its amount can be determined by shaking 1 or 2 c.c. of the alcohol with 20 or 30 c.c. of normal aqueous KOH, adding 20 or 30 c.c. of a decinormal solution of iodine, until the solution is clear. The liquid is then acidified with HCl (S.G. 1.025), excess of decinormal sodium thiosulphate added, and the excess determined by titrating back with iodine solution. If 1 c.c. of methyl alcohol be taken, the weight of acetone in 100 c.c. will be found by multiplying the amount of iodine used up by 7.612 (Messinger, *B.* 21, 3366; cf. Krämer, *B.* 13, 1002; Hintz, *Fr.* 27, 182).

The estimation of methyl alcohol in ethyl alcohol can be effected by oxidation with a standard solution of K₂Cr₂O₇ for 1 pt. of ethyl alcohol reduces 4.278 pts. of the dichromate in becoming oxidised to acetic acid, while 1 pt. of methyl alcohol, in being oxidised to CO₂ and water, reduces 9.224 pts. of K₂Cr₂O₇. A solution of 80 g. K₂Cr₂O₇ and 150 c.c. H₂SO₄ per litre is employed, and the unreduced chromate estimated volumetrically (O. Hehner, *An.* 12, 25).

When 10 c.c. of pure ethyl alcohol are shaken with 1 c.c. of a 1 p.c. solution of KMnO₄ at 20°, no reduction takes place for 20 minutes, but if the ethyl alcohol contains crude wood

spirit, decolourisation takes place at once (Haber-mann, *Fr.* 27, 668).

Reactions.—1. Passage through a *red-hot* tube yields acetylene and other products (Berthelot, *C. R.* 50, 805).—2. In contact with *platinum-black* and air it is oxidised to formic aldehyde and formic acid.—3. Heated with *ammonium chloride* in a sealed tube at 300° it yields mono-, di-, and tri-methylamine (Berthelot).—4. *Bleaching-powder* does not yield chlroform (Goldberg, *J. pr.* [2] 24, 115).—5. *Potassium* gives off hydrogen, forming KOMe.—6. When its vapour is passed over heated *potash*, hydrogen is given off, and potassium formate, oxalate, and carbonate are successively formed.—7. Conc. H_2SO_4 forms $HMeSO_4$, which, when heated with excess of methyl alcohol, yields di-methyl oxide. When distilled with excess of H_2SO_4 di-methyl sulphate passes over.—8. Converted into methyl chloride by treatment with HCl, with PCl_3 , or with S_2Cl_2 . The joint action of H_2SO_4 and HBr gives rise to methyl bromide and ethyl bromide (Niemiłowitch, *M.* 10, 820).—9. $SOCl_2$ forms $MeSH$, Me_2SO , $MeCl$, and other products (Carius, *A.* 111, 93).—10. SO_2 forms $CH(OH)(SO_3H)_2$ (Max Müller, *B.* 6, 1031).—11. When acidulated with 5 p.c. sulphuric acid and submitted to electrolysis it forms CO_2 , CO , methyl formate, methyl sulphate, and methylal (Renard, *C. R.* 80, 236).—12. Distillation over heated *zinc-dust* splits it up into CO and hydrogen, a very little methane being also formed (Jahn, *B.* 13, 983; *M.* 1, 378).—13. *Zinc chloride* forms CH_4 , water, Me_2O , hexa-methylbenzene, and traces of propylene, butylene, and other hydrocarbons (Le Bel a. Greene, *C. R.* 87, 260; 89, 413).—14. *Aldehyde*. (1 vol.), $MeOH$ (2 vols.), and HCl form $CH_3CH(OMe)_2$ (Claus a. Trainer, *B.* 19, 3004).—15. Not affected by *B. acti* growing in solutions containing it (Brown, *C. J.* 49, 177).—16. Converts *m*- and *p*-*diazo-benzoic acid* into $C_6H_5(OMe)CO_2H$, while *o*-*diazo-benzoic acid* only gives benzoic acid (Griess, *B.* 21, 378).—17. When heated with hydrochlorides of aromatic bases (e.g. aniline, xylidine, piperidine) it often displaces hydrogen in the nucleus by methyl (Hofmann, *B.* 15, 2895; Ladenburg, *B.* 16, 2057).—18. Unlike $EtOH$, it hardly reacts when heated with phenol and $ZnCl_2$ (Auer, *B.* 17, 669).—19. Unlike butyl and amyl alcohols, it does not form a homologue of benzene when heated with benzene and $ZnCl_2$ at 270° (Goldschmidt, *B.* 15, 1066).—20. $ClCONH_2$ forms methyl allophanate $NH_2CO.NH.CO.Me$ [208°] (Gattermann, *A.* 244, 40).

Metallic derivatives.—KOMe. Obtained by dissolving K in methyl alcohol.— $(KOH)_2(MeOH)_2$ or $(KOMe)_2(MeOH)_2, 3aq.$ [ρ . 110°]. Obtained by evaporating a solution of KOH in methyl alcohol (Göttig, *B.* 21, 1832). Large elastic plates, somewhat heavier than water, on which they move about rapidly, being decomposed.— $(NaOH)_2(MeOH)_2$ or $(NaOMe)_2MeOH$ aq. Obtained by dissolving NaOH in dry MeOH and evaporating. Crystalline mass, which moves about on the surface of water while decomposing and dissolving.— $NaOMe$ liq. Obtained by evaporating a solution of NaOH in not quite dry methyl alcohol (Göttig, *B.* 21, 561).— $NaOMe(MeOH)_2$ (Fröhlich, *A.* 202, 295). CO passed over $NaOMe$ at 160°

forms acetic acid.* CO passed into a hot mixture of $NaOMe$ and $NaOAc$ forms propionic acid (Geuther a. Fröhlich, *A.* 202, 312). When distilled with the Ba salt of a carboxylic acid it displaces the carboxyl by hydrogen. Thus succinic acid may be converted into propionic acid (Mai, *B.* 22, 2135).— $TiOMe$. From $TiOEt$ and excess of $MeOH$ (Lamy, *J.* 1864, 466).— $(Ba(OMe)_2)_2BaO.H_2$ aq. White nacreous plates, obtained by evaporating at 185° a solution of BaO in $MeOH$ (De Forcrand, *C. R.* 102, 1397, 1557). Perhaps identical with $Ba(OMe)_2$ aq. described by Dumas and Péligot (*A. Ch.* 58, 17). 1 litre of $MeOH$ dissolves 200 g. of BaO. The heat of formation of the compound from solid $3BaO$ and liquid $4MeOH$ is 43,500. If a considerable quantity of water is added to the solution of BaO in $MeOH$ the hydrate $BaO.10aq$ is precipitated. The compound $BaO_2Ba(OMe)_2, 2aq$ is readily formed, even if as much as 3 p.c. water be present in the methyl alcohol, but by evaporating in the cold over H_2SO_4 , crystals of $Ba(OMe)_2, 3aq$ are formed. These are sol. water and alcohol. By passing HCN into a solution of baryta in methyl alcohol there is formed barium cyanomethylate $Ba(OMe)CN.MeOH$. This is a crystalline powder, sol. water, less sol. methyl alcohol. It loses at 100° the methyl alcohol of crystallisation.

Combinations.— $CaCl_2.4MeOH$. Methyl alcohol dissolves $CaCl_2$ with great rise of temperature, and on cooling this compound separates in large six-sided tables (Kane, *A.* 19, 168). It is not decomposed at 100°, but water readily liberates the $MeOH$.— $LiCl.3MeOH$.— $MgCl_2.6MeOH$ (Simon, *J. pr.* [2] 20, 377).— $SbCl_3.6MeOH$. [81°]. Slightly yellow crystals (from hot alcohol); decomposes at 130°, giving off $MeCl$ and HCl (W. C. Williams, *C. J.* 30, 463).— $CuSO_4.2MeOH$. Minute bluish-green crystals, obtained by shaking anhydrous $CuSO_4$ with methyl alcohol (Forcrand, *C. R.* 102, 551).

METHYL ALDEHYDE is FORMIC ALDEHYDE.

METHYL-ALIZARIN v. DI-OXY-METHYL-ANTHRAQUINONE.

METHYL-ALLANTOIN $C_5H_7N_3O_4$, [225°]. Formed by oxidising methyl-uric acid with cold aqueous $KMnO_4$ (Hill, *B.* 9, 1090). Monoclinic prisms; decomposed by fusion. V. sol. hot water, sl. sol. alcohol, insol. ether. Conc. $HIAq$ splits it up into urea and methyl-hydantoin.— $AgC_5H_7N_3O_4$; prisms, sl. sol. cold water.

METHYL-ALLOXAN $C_5H_7N_3O_4$, i.e. $CO \begin{smallmatrix} NH.CO \\ \backslash \\ NMe.CO \end{smallmatrix} CO$. Formed by oxidising

methyl-uric acid with HNO_3 or with $KClO_4$ and HCl (Hill, *B.* 9, 1092). Formed also by treating theobromine (2 pts.) with $KClO_4$ (9 pts.) and HCl (56 g. 1.06) at 50° (Maly a. Andreasch, *M.* 3, 108; cf. Fischer, *A.* 215, 304). It is converted by alkalis into methyl-alloxanic acid, and by boiling HNO_3 into methyl-parabanic acid. H_2S forms di-methyl-alloxantin. $KHSO_4$ forms a compound $B.KHSO_4$ aq. which crystallises in large monoclinic prisms.

Di-methyl-alloxan $C_6H_9N_3O_4$, i.e.

$CO \begin{smallmatrix} NMe.CO \\ \backslash \\ NMe.CO \end{smallmatrix} CO$. A product of the action of $KClO_4$ and HCl on caffeine at 50°. It is extracted by ether (E. Fischer, *A.* 215, 257; Maly a. Andreasch, *M.* 3, 92). Colourless six-sided

tables (containing 2aq), which slowly turn red in air. V. sol. water, almost insol. alcohol, insol. ether. Dyes the skin red. With FeSO_4 and ammonia it gives a characteristic indigo colouration. After drying over H_2SO_4 it is left as an amorphous powder (containing aq), sol. alcohol and ether. Di-methyl-alloxan decomposes at 100° . It prevents the ppn. of cupric and ferric salts by potash. Hydrogen sulphide converts it into amalic acid. KHSO_4 forms the compound $\text{C}_4\text{H}_4\text{N}_2\text{O}_4\text{KHSO}_4$, which crystallises in long tablets, S. 7.2 at 20° , almost insol. alcohol, insol. ether. This compound may be crystallised from warm water, and does not give the indigo colouration with FeSO_4 and ammonia.

METHYL-ALLOXANTIC ACID $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$. Formed by the action of alkalis on methyl-alloxan. When the product of the action of HNO_3 on methyl-uric acid is neutralised with CaCO_3 , and then mixed with alcohol and ammonia the salt $\text{CaC}_4\text{H}_4\text{N}_2\text{O}_5$ is ppd. (Hill, B. 9, 1092). This salt is gelatinous, and when boiled with water it gives off methylamine.

METHYL-ALLOXANTIN $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$. Obtained by mixing solutions of dialuric acid and methyl-alloxan (Andreasch, M. 3, 431). Crystallises from water in minute thin tablets (containing 3aq).

s-Di-methyl-alloxantin $\text{C}_{10}\text{H}_{10}\text{N}_4\text{O}_5$ i.e.

Formed by passing H_2S into an aqueous solution of methyl-alloxan (Maly a. Andreasch, M. 3, 109). Thin plates (containing 4aq); almost insol. alcohol and ether, sl. sol. cold water. Turns red in air. Gives a red colouration with ammonia, and a violet colouration with potash or baryta (Andreasch, M. 3, 109).

u-Di-methyl-alloxantin

Formed by reducing di-methyl-alloxan to di-methyl-dialuric acid, and ppg. the aqueous solution of this acid with alloxan (Andreasch, M. 3, 428). Crystallises from hot water in minute four-sided pyramids (containing aq); insol. alcohol and ether.

Tetra-methyl-alloxantin v. AMALIC ACID.

METHYL-ALLYL v. BUTYLENE.

METHYL-ALLYL-ACETO-ACETIC ACID v. ACETO-ACETIC ACID.

DI-METHYL-ALLYL-AMINE. *Methyloliodide* $\text{C}_4\text{H}_9\text{NMe}_2$. From allylamine and MeI (Bodo, B. 20, Ref. 137). When distilled with KOH it yields NMe_3 and an aldehyde $\text{C}_4\text{H}_8\text{O}$ (130° – 135°).

p-METHYL-ALLYL-BENZENE $\text{C}_{10}\text{H}_{12}$ i.e. $\text{CH}_3\text{C}_6\text{H}_4\text{C}_3\text{H}_5$. *p-Allyl-toluene*. (192°). Formed from cymene by chlorinating and heating the resulting $\text{CH}_3\text{C}_6\text{H}_4\text{C}_3\text{H}_5\text{Cl}$ with alcoholic KOH (Errera, G. 14, 288, 505). Liquid. Combines with bromine. KMnO_4 oxidises it to *p*-toluic acid. HBrAq (S.G. 1.59) at 200° forms a polymeride ($\text{C}_{10}\text{H}_{12}$) $_x$ (350°), and this on keeping changes to an amorphous solid, which by distillation is re-converted into *p*-methyl-allylbenzene.

METHYL-DI-ALLYL-CARBINOL v. OCTENYL ALCOHOL.

Di-methyl-allyl-carbinol v. HEXENYL ALCOHOL.

METHYL-ALLYL-CHLORACETOL v. DI-CHLORO-HEXYLENE.

METHYL ALLYL ETHER v. METHYL ALLYL OXIDE.

METHYL ALLYL DIKETONE $\text{C}_8\text{H}_8\text{O}_4$ i.e. $\text{CH}_3\text{CO.CO.C}_3\text{H}_5$. *Acetyl-crotonyl*. ($c. 130^\circ$). Obtained by distilling its mono-oxim with dilute H_2SO_4 (Otte a. Von Pechmann, B. 22, 2124). Yellow oil with irritating odour. Not obtained pure.

Mono-oxim $\text{CH}_3\text{CO.C(OH).C}_3\text{H}_5$. *Nitroso-allylacetone*. *Methyl nitroso-butenyl ketone*. (46°). From allyl-aceto-acetic acid and nitrous acid. White plates (from ligroin), v. sol. usual menstrua. Its solution in NaOH aq is yellow.

Di-oxim $\text{CH}_3\text{C(NO).C(OH).C}_3\text{H}_5$. (135°). Formed from the mono-oxim by warming with hydroxylamine. Small plates.

Phenyl-hydrazide oxim

$\text{CH}_3\text{C(N.HPh).C(OH).C}_3\text{H}_5$. (137°). Brownish-red needles (from benzene and ligroin).

METHYL ALLYL OXIDE $\text{C}_4\text{H}_8\text{O}$ i.e. $\text{CH}_3\text{O.C}_3\text{H}_5$. *Allyl methyl ether*. (46°). S.G. 1.177. H.F.p. 34.080. H.F.v. 32.050. From allyl bromide and NaOMe (Henry, B. 5, 455). With bromine it forms $\text{CH}_3\text{O.CH}_2\text{CHBr.CH}_2\text{Br}$ (186°). ICl gives $\text{CH}_3\text{O.C}_3\text{H}_5\text{Cl}$ (196°) (Silva, B. 8, 1469).

METHYL-ALLYL-PROPYL-CARBINOL v. OCTENYL ALCOHOL.

METHYL ALLYL SULPHIDE $\text{C}_4\text{H}_8\text{S}$ i.e. $\text{CH}_3\text{S.C}_3\text{H}_5$. ($c. 92^\circ$). V.D. 43.36. Formed by heating lead methyl mercaptide $(\text{CH}_3\text{S})_2\text{Pb}$ with allyl bromide and ether at 100° (Obermeyer, B. 20, 2925).

METHYL ALLYL THIO-UREA

$\text{CH}_3\text{NH.CS.NH.C}_3\text{H}_5$. (50 – 55°). Formed from allylamine and methyl thio-carbimide or from methylamine and allyl thio-carbimide (O. Hecht, B. 23, 286). White mass.

METHYL-AMIDO-ACETIC ACID $\text{C}_4\text{H}_7\text{NO}_2$ i.e. $\text{CH}_3\text{NH.CH}_2\text{CO}_2\text{H}$. *Methyl-glycocol*. *Sarcosine*. Mol. w. 89. (210° – 215°). Formed by the action of boiling baryta-water on creatine or caffeine (Liebig, A. 62, 310; Rosengarten a. Strecker, A. 157, 1; Schilling, C. C. 1884, 811). Formed also by heating chloro-acetic ether with aqueous methylamine at 125° (Volhard, A. 123, 261).

Properties.—Trimetric prisms, v. e. sol. water, sl. sol. alcohol. Has a somewhat sweet taste. Heated to 210° – 220° the greater part evolves H_2O giving the anhydride $\text{C}_4\text{H}_7\text{NO}_2$, whilst a smaller portion splits up into di-methyl-amine and CO_2 (Mylius, B. 17, 286). Chloride of cyanogen passed into the fused substance gives methyl-hydantoin and sarcosine-anhydride (Traube, B. 15, 2110). When taken internally, the greater part passes as such into the urine (Batman a. Mering, B. 8, 587; Salkowski, H. 4, 107; Schiffer, H. 5, 266). Nitrous acid passed into its hot aqueous solution forms a nitroso-derivative $\text{CH}_3\text{N(NO).CH}_2\text{CO}_2\text{H}$, which is a thick liquid, forming the salt CaA , aq crystallising in needles (Schultzen, Z. 1867, 616). Gives methyl-uric acid when heated with urea (Horbaczewski, M. 6, 356).

Salts.—($\text{C}_4\text{H}_7\text{NO}_2$) $_2\text{Cu}$ 2aq: ultramarine blue crystals (E. Schmidt, A. 217, 278).— $\text{C}_4\text{H}_7\text{NO}_2\text{HCl}$: needles (from alcohol).—($\text{C}_4\text{H}_7\text{NO}_2$) $_2\text{Zn.H}_2\text{O}$: S. (alcohol) 0.98 . V. e. sol. water (Bulliginsky, J.).

1867, 495).— $(C_2H_5NO)_2H_2PtCl_4$, 2aq: monoclinic tables, $a:b:c = 1.0331:1:0.6747$; $\beta = 75^\circ 27'$. — $C_2H_5NO_2HAuCl_4$: yellow needles, sl. sol. cold water.— $C_2H_5NO_2HNO_3$. [c. 70°]. Very hygroscopic, v. sol. cold alcohol (Franchimont, *R. T. C.* 2, 339).— $(C_2H_5NO_2)_2H_2SO_4$, aq: four-sided tables, v. e. sol. water. S. (boiling alcohol) 10.

Guanidine hydrochloride $C_2H_5NO_2HClCH_2N_3$. Formed by heating methyl-amido-acetic acid with guanidine hydrochloride (Baumann, *B.* 7, 1151). Tables (from alcohol).

Anhydride $C_2H_5N_2O_2$, i.e.

$CH_3N.CH_2.CO$

$OC.CH_2.N.CH_3$ (?). *Sarcosine anhydride*.

[150°]. Formed by the action of cyanogen chloride on melted sarcosine. Prepared by heating sarcosine to 210° – 220° and distilling the residue (Traube, *B.* 15, 2112; Mylius, *B.* 17, 286). Colourless prisms. V. sol. water, alcohol, and ether. Bitter taste. Weak base. By boiling with water it again gives sarcosine. On oxidation with $KMnO_4$ it yields *s*-di-methyl-oxamide.

Salts. — $B'_2H_3Cl_2PtCl_4$, 2aq: prisms. — $B'_2H_3Cl_2PtCl_4$, 4aq: large six-sided tables. — $B'_2H_3ClAuCl_4$, 2aq: prisms.

Sarcosine-uric acid $C_2H_5O_4N_3$. Obtained by heating a mixture of sarcosine (3 pts.) and uric acid (2 pts.) at 210° ; a good yield is obtained.

Properties.—Colourless prismatic crystals (containing 2aq). Sol. hot water. It shows the murexide reaction. It slowly reduces alkaline solutions of copper. It has weak acid and basic properties, dissolving in aqueous acids and alkalis. By fusion with KOH at 110° it is resolved into uric acid and sarcosine. Heated with bromine water it is converted into bromo-sarcosine-mesouric acid $C_2H_5N_3O_3Br$.

Salts.—The acetate forms microscopic crystals, sl. sol. hot acetic acid, insol. cold $HOAc$, v. sol. water. The formate is very analogous to the acetate. The ammonium salt is crystalline.— $A''Ag_2$; insol. white amorphous pp. (Mylius, *B.* 17, 518).

Bromo-sarcosine-mesouric acid $C_2H_5N_3O_3Br$. Formed by digesting a warm aqueous solution of sarcosine-uric acid with bromine, which gives a nearly theoretical yield (Mylius, *B.* 17, 521). Heavy colourless tables. Sl. sol. water. By H_2S it is reduced to sarcosine-mesouric acid. It is readily decomposed by alkalis, but is stable towards acids.

Sarcosine-mesouric acid $C_2H_5O_4N_3$. Obtained by reducing a hot aqueous solution of bromo-sarcosine-mesouric acid with H_2S (Mylius, *B.* 17, 524). Trimetric tables or needles. V. sol. water, insol. alcohol. It is a strong acid, but also possesses weak basic properties. By bromine water it is reconverted into the bromo-derivative; similarly chlorine-water gives the chloro-derivative. It is very oxidisable, reducing $AuCl_3$, alkaline, copper solution, $KMnO_4$, &c., very readily.

Salts.—The acetate forms an unstable crystalline pp., sl. sol. acetic acid.— $A''HNH_4$: fine needles, v. sol. water.— $A''Ag_2$: white amorphous pp.

Tri-methyl-amido-acetic acid internal anhydride v. *BETAINE*.

DI-METHYL-AMIDO-ACETIC OETHALDEHYDE. *Methylohydroxide* $C_2H_5NO_2$, i.e. $CH_3(NMe_2OH).CH(OEt)_2$. *Muscarine*. Occurs, together with neurine, in the fly agaric (Schmiedeberg a. Koppe, *J.* 1870, 875). Formed from neurine by oxidation with conc. HNO_3 (Schmiedeberg a. Harnack, *J.* 1876, 804). Deliquescent crystalline mass, sol. alcohol. Alkaline in reaction. Active narcotic poison. Separated from neurine by placing the mixed hydrochlorides on filter-paper, when the muscarine salt deliquesces and is absorbed by the paper (Harnack, *J.* 1876, 803).— $B'(C_2H_5NO_2Cl)_2PtCl_4$, 2aq:— $C_2H_5NO_2AuCl_4$.

Di-ethyl derivative of the methylohydroxide $C_2H_5NO_2$, i.e. $CH_3(NMe_2OH).CH(OEt)_2$. *Hydroxide of tri-methyl-amido-acetal*. When chloro-acetal $CH_3Cl.CH(OEt)_2$ is treated with tri-methyl-amine there is formed $CH_3(NMe_2Cl).CH(OEt)_2$ and C_2H_5NOCl , which is probably $CH_3(NMe_2Cl).CHO$. The two salts are separated by fractional ppn. by platinic chloride.— $(C_2H_5NO_2Cl)_2PtCl_4$: orange crystals, sl. sol. cold water.— $C_2H_5NO_2AuCl_4$: lemon-yellow needles.

Di-methyl-amido-acetic aldehyde. *Methylohydroxide* $C_2H_5NO_2$, i.e. $CH_3(NMe_2OH).CHO$. Formed by saponifying $CH_3(NMe_2OH).CH(OEt)_2$ with baryta (Berlinerblau, *B.* 17, 1142). The hydrochloride $C_2H_5NO_2Cl$ is also formed as above. Gives the aldehyde reactions.—Platinochloride $(C_2H_5NO_2Cl)_2PtCl_4$: octahedra (from dilute alcohol).

DI-METHYL-AMIDO-ACETONE. *Methylochloride*. C_2H_5NOCl i.e. $CH_3.CO.CH_2.NMe_2Cl$. *Caprine chloride*. Formed by the action of dry NMe_3 upon chloro-acetone in the cold (Niemitsch, *M.* 7, 241). Very deliquescent shining needles; sol. alcohol. Gives the alkaloidal reactions. Acts physiologically like curare.— $C_2H_5NOClAuCl_4$, [1897].

p-DI-METHYL-AMIDO-ACETOPHENONE $C_6H_5(NMe_2).CO.CH_3$, [59°]. Formed by methylation of *p*-amido-acetophenone (Klingel, *B.* 18, 2694). Yellowish plates (from hot water). V. sol. alcohol, ether, and hot water.

o-DIMETHYL-AMIDO-ANISOL v. **o-DI-METHYL-AMIDO-PHENOL methyl ether**.

METHYL-AMIDO-AZO-COMPOUNDS v. **Azo-COMPOUNDS**.

METHYL-AMIDO-BENZAMIDE v. *Amide of METHYL-AMIDO-BENZOIC ACID*.

METHYL-AMIDO-BENZENE v. **METHYL-ANILINE** and **TOLUIDINE**.

Di-methyl-amido-benzene v. **XANTHINE**, **METHYL-TOLUIDINE**, and **DI-METHYL-ANILINE**.

Tri-methyl-amido-benzene v. **MESIDINE** and **ψ -CUMIDINE**.

Tetra-methyl-amido-benzene v. **TETRA-METHYL-PHENYL-AMINE**.

Tetra-methyl-di-amido-benzene v. **TETRA-METHYL-PHENYLENE DIAMINE**.

Di-methyl-tri-amido-benzene $C_6H_3(NMe_2)(NH_2)_3$, [1:8:4]. [44°] (298°). Needles. Readily turned blue in the air. Prepared by reduction of dinitro-dimethyl-aniline [87°]. Formed also by reduction of nitro-*p*-dimethyl-amidophenyl-oxamic ether.

Acetyl derivative $C_6H_3(NMe_2)(NH_2)(NHAc)$, [153°]. Prisms (containing aq) (Wurster a. Sendtner, *B.* 12, 1805).

***o*-Tri-methyl-tri-amido-benzene**
 $C_6H_3(NMe_2)(NH_2)(NHMe)$ [1:2:4]. [90°]. (294°). Prepared by reduction of the nitrosamine derived from nitro-trimethyl-*p*-phenylene-diamine (Wurster a. Schobig, *B.* 12, 1812). White needles. Sol. water. Gives a blue colouration with HNO_3 .

Diacetyl derivative [184°]. Leaflets.

METHYL-AMIDO-BENZENE-AZO-COMPOUNDS *v.* Azo-compounds and *Dis-azo*-compounds.

DI-METHYL-AMIDO-BENZENE PHOSPHINIC ACID $NMe_2.C_6H_4.P(OH)_2$. [162°]. Formed by decomposing its chloride with water (Schenk a. Michaelis, *B.* 21, 1498). White needles; *v.* sol. hot water and alcohol. On boiling its aqueous solution it is split up into di-methyl-aniline and phosphorous acid. When heated alone it gives phosphorus, PH_3 , and di-methyl-aniline.

Salt.— $NaHA$ 2aq: large crystals (from alcohol).

Chloride $NMe_2.C_6H_4.PCl_2$. [66°]. (250° at 120 mm.). Formed by the action of PCl_3 (100 g.) on di-methyl-aniline (70 g.) in presence of $AlCl_3$ (20 g.). The mixture is boiled for eight hours with inverted condenser, and the product extracted with petroleum ether and distilled *in vacuo*. Thin plates; *v.* sol. benzene, *m.* sol. ether, *sl.* sol. petroleum ether. Converted by the action of chloro-benzene and sodium into di-methyl-amido-tri-phenyl-phosphine.

DI-METHYL-AMIDO-BENZENE PHOSPHONIC ACID. $NMe_2.C_6H_4.PO(OH)_2$. [133°]. Formed by oxidising $NMe_2.C_6H_4.P(OH)_2$ with $HgCl_2$ (Schenk a. Michaelis, *B.* 21, 1500). Crystals; *v.* *e.* sol. water and alcohol.

METHYL-AMIDO-BENZENE SULPHONIC ACID $C_6H_5NSO_3$, *i.e.* $NHMe.C_6H_4.SO_3H$. Formed, together with methane disulphonic acid, by heating the acetyl derivative of methyl-anilino with H_2SO_4 at 145° (Smyth, *ibid.* 7, 1240). Crystals, which decompose at 182° without previous fusion. — BaA' 2aq: crystalline powder.

Methyl-amido-benzene sulphonic acid
 $NHMe.C_6H_4.SO_3H$. Formed by heating methyl-aniline ethyl sulphate at 210° (Mundelius, *B.* 7, 1850). Plates (containing aq); *insol.* alcohol and ether. — BaA' 8aq: small prisms. — CaA' 4aq. — PbA' 8aq.

Di-methyl-amido-benzene *p*-sulphonic acid
 $NMe_2.C_6H_4.SO_3H$. [150°] (*S.*); [257°] (*M. a. G.*).

Formation.—1. By heating di-methyl-aniline with rather more than the equivalent quantity of sulphuric acid at 185° (Smyth, *B.* 6, 844; 7, 1287; Armstrong, *B.* 6, 663; Vignon, *C. R.* 107, 263).—2. From di-methyl-aniline and $ClSO_2Et$ (Wenghöfer, *J. pr.* [2] 16, 448).—3. From bromo-di-methyl-aniline and H_2SO_4 at 180° (Michler a. Walder, *B.* 14, 2177).—4. From di-methyl-aniline and $SOCl_2$ followed by water (Michaelis a. Godchaux, *B.* 23, 555).

Properties.—8-sided prisms (containing aq). Decomposes at 230°.

Salts.— BaA' 3aq: needles or plates. — BaA' 5aq (Vignon). — BaA' 11aq: efflorescent triclinic crystals (Laar, *J. pr.* [2] 20, 262). — NaA' 2aq. Long needles, *m.* sol. water, *sl.* sol. aqueous $NaOH$, *insol.* water (*M. a. G.*)

Chloride $C_6H_4(NMe_2)SO_2Cl$.

Ethyl ether EtA'. [85°]. Formed from alcohol and the chloride.

Di-methyl-amido-benzene *p*-sulphonic acid.

Anhydride of the methylo-hydroxide

$C_6H_5NSO_3$, *i.e.* $C_6H_4\langle\begin{smallmatrix} NMe_2 \\ SO_2 \end{smallmatrix}\rangle O$. Formed by allowing a mixture of amido-benzene *p*-sulphonic acid, MeI , conc. KOH aq, and $MeOH$ to stand for some time in the cold (Griess, *B.* 12, 2116). Four-sided plates; *v.* sol. cold water, almost *insol.* alcohol, *insol.* ether. Decomposes before fusion. Ppd. as periodide by a solution of iodine in $HIAq$. — $(SO_3H.C_6H_4.NMe_2Cl)_2PtCl_4$ 8aq: orange tables, *v.* *e.* sol. cold water.

METHYL-*o*-AMIDO-BENZOIC ACID.

Amide $NHMe.C_6H_4.CONH_2$. [160°]. Formed by heating *o*-amido-benzamide with MeI at 100° (Weddige, *J. pr.* [2] 36, 152). Plates; *v.* sol. hot alcohol, sol. water. In dilute solutions it shows blue fluorescence.

Acetyl derivative

$NHMe.C_6H_4.CO.NHAc$. [155°]. Long needles; *v.* sol. hot alcohol, *sl.* sol. benzene and ether. When heated above 155° it forms the anhydride-derivative $C_6H_4\langle\begin{smallmatrix} CO.N \\ CO.N \end{smallmatrix}\rangle CMe$ [199°] which is an oxy-di-methyl-quinoxaline.

Nitroso-derivative of the amide

$NO.NMe.C_6H_4.CO.NH_2$. [149°]. Pale yellow prisms (from hot alcohol) (Finger, *J. pr.* [2] 37, 431).

Methyl-*m*-amido-benzoic acid $C_6H_5NO_2$, *i.e.* $NHMe.C_6H_4.CO_2H$. Formed by boiling (α)-benzcreatin $NH_2.C(NH_2)NHMe.C_6H_4.CO_2H$ with baryta-water (Griess, *B.* 8, 325). Nodular groups of plates; *v.* sol. hot water. Nitrous acid ppts. a nitroso-derivative. Salt.— $C_6H_5NO_2.HCl$: six-sided plates.

Di-methyl-*m*-amido-benzoic acid $C_6H_5NO_2$, *i.e.* $NMe_2.C_6H_4.CO_2H$. [151°]. Obtained by saponifying its methyl ether. Needles, *sl.* sol. hot water.

Methyl ether $NMe_2.C_6H_4.CO_2Me$. (210° uncor.). Obtained by fusing the isomeric anhydride of the methylo-hydroxide (*v. infra*) (Griess, *B.* 6, 587). Heavy yellowish oil, sol. acids.— $C_6H_5MeNO_2.H_2SO_4$: very small prisms, *sl.* sol. dilute sulphuric acid, *v.* sol. water.— $(C_6H_5MeNO_2)_2H_2PtCl_6$: spindle-shaped laminæ, *v.* *sl.* sol. cold water.

Anhydride of the methylo-hydroxide

$C_6H_5NO_2$, *i.e.* $C_6H_4\langle\begin{smallmatrix} NMe_2 \\ CO \end{smallmatrix}\rangle O$. *Benzbetaine*.

Formed by allowing a mixture of *m*-amido-benzoic acid with $MeOH$ (1 mol.), aqueous KOH (3 mols.), and MeI (3 mols.) to stand in the cold; the product, after freeing from $MeOH$ by distillation, being saturated with HI , whereupon the iodide $NMe_2.I.C_6H_4.CO_2H$ is ppd. This iodide is then boiled with water and lead hydroxide (Griess). Small deliquescent needles (containing aq), which give up their water of crystallisation at 105°. *V. o.* sol. cold alcohol, *insol.* ether. Tastes bitter and is neutral in reaction. Forms $(NMe_2.Cl.C_6H_4.CO_2H)_2PtCl_4$ 4aq crystallising in large prisms, *sl.* sol. hot water.

Methylo-iodide $NMe_2.I.C_6H_4.CO_2H$. Formed as above. Small short prisms (containing aq); *sl.* sol. cold water.

Methylo-chloride $NMe_2.Cl.C_6H_4.CO_2H$.

Monoclinic crystals; $a:b:c = 1.939:1.0876$; $\beta = 88^\circ 49'$ (Zingel, Z. K. 10, 414).

Di-methyl-*p*-amido-benzoic acid

$\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$. [235°]. Formed by boiling its chloride with water. Prepared by boiling for three hours a mixture of *p*-amido-benzoic acid (1 mol.), MeI (2 mols.), and aqueous KOH (3 mols.) dissolved in methyl alcohol (Michler, B. 9, 400). Obtained also by heating tetra-methyl-di-amido-benzophenone with soda-lime at 340° , extracting the product with hot water, and ppg. by acetic acid (E. Bischoff, B. 22, 341). Short needles (from alcohol); sol. aqueous KOH and HClAq, insol. dilute acetic acid. Nitrous acid forms $\text{NMe}_2\text{C}_6\text{H}_4(\text{NO})\text{CO}_2\text{H}$ [224°]. The Ca salt forms yellowish plates.

Methyl ether $\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{Me}$. [102°]. Silvery plates (from alcohol); v. sol. benzene, ether, and chloroform, m. sol. dilute alcohol. Nitrous acid forms $\text{NMe}_2\text{C}_6\text{H}_4(\text{NO})\text{CO}_2\text{Me}$ [101°].

Chloride $\text{NMe}_2\text{C}_6\text{H}_4\text{COCl}$. Obtained by heating di-methyl-aniline with COCl_2 at 50° in a sealed tube (Michler). Crystalline.

Nitrile $\text{NMe}_2\text{C}_6\text{H}_4\text{CN}$. From di-methyl-*p*-phenylene-diamine by Sandmeyer's reaction (Ahrens, B. 20, 2958).

Anhydride of the methyl-hydroxide

$\text{C}_6\text{H}_4\text{NO}_2$, i.e. $\text{C}_6\text{H}_4\text{CO}(\text{NMe}_2)_2$. [255°]. When *p*-amido-benzoic acid is mixed with MeI, KOH, and methyl alcohol, there is formed, even in the cold, di-methyl-*p*-amido-benzoic acid and the iodide $\text{NMe}_2\text{I.C}_6\text{H}_4\text{CO}_2\text{H}$ which crystallises in short yellow plates [233°] (Michael a. Wing, Am. 7, 195). The corresponding anhydride crystallises from alcohol in colourless plates (containing aq); v. sol. water. It loses its water of crystallisation at 100° . The periodide forms long dark prisms [200°]. The platinochloride ($\text{NMe}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$), PtCl_4 , forms large red prisms.

Tetra-methyl-di-amido-benzoic acid. Di-methyl-di-hydroxide

$(\text{HO.NMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ [1:3:5]. The iodide $(\text{INMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ is formed when di-amido-benzoic acid (1 pt.) is mixed with MeI (6 pts.), methyl alcohol (10 pts.), and twice as much of a concentrated solution of KOH as is required to neutralise the acid. The mixture should stand for some time, being kept alkaline by further additions of potash. The alcohol is then distilled off, and the iodide ppd. by HIAq (Griess, B. 7, 39). This iodide crystallises from hot water in six-sided tables or plates, v. sol. hot water. With moist Ag_2O it yields a caustic alkaline liquid which, on evaporation, leaves the hydroxide as a hygroscopic mass of soft white plates. It rapidly absorbs CO_2 and ppt. metallic oxides from their salts. The corresponding chloride $(\text{NMe}_2\text{Cl})_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ 4aq, obtained by neutralising the hydroxide by HCl , crystallises in small six-sided plates, v. sol. water, sl. sol. hot alcohol. The periodide forms brownish-yellow needles. The carbonate $\text{CO}(\text{O.NMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ 8aq, obtained from the iodide and Ag_2CO_3 , crystallises from water in very small soluble plates, having an alkaline reaction. The platinochloride $(\text{ClNMe}_2)_2\text{C}_6\text{H}_4\text{CO}_2\text{H.PtCl}_4$ 8aq is a pp. composed

of very small pale-yellow plates, usually grouped in stars.

Derivative v. CHLORO-METHYL-AMIDO-BENZOIC ACID.

DI-METHYL-*p*-AMIDO-BENZOIC ALDEHYDE, $\text{C}_6\text{H}_4\text{NO}$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{CHO}$. [73°]. Formed, together with CHCl_3 , by heating $\text{NMe}_2\text{C}_6\text{H}_4\text{CH}(\text{OH})\text{COCl}$ with alcoholic KOH (Bössneck, B. 18, 1520; 19, 366). With di-methyl-aniline and hydrochloric acid it forms $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CH}$.

Oxim $\text{NMe}_2\text{C}_6\text{H}_4\text{CH.NOH}$. [144°]. Yellowish-brown plates (Knöder a. Bössneck, B. 20, 3195).

Phenyl hydrazide $\text{NMe}_2\text{C}_6\text{H}_4\text{CH.N}_2\text{HPh}$. [148°]. Needles (from alcohol).

DIMETHYL-AMIDO-BENZOPHENONE

$\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_4\text{NMe}_2$. *Benzodimethylaniline. Benzoyl-di-methyl-anilina. Benzoyl-phenyl-di-methyl-amine*. [90°]. Formed by heating the methyl-iodide to 181° . Formed also by heating malachite green $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OH})\text{C}_6\text{H}_5$ with conc. HClAq at 180° . Colourless plates (from alcohol). Insol. water, sl. sol. cold alcohol, v. e. sol. hot alcohol or ether. It is a feeble base, its solution in concentrated acids being ppd. by water.

Methyl-iodide $\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_4\text{NMe}_2\text{I}$. Large tables, sl. sol. cold water. Formed by heating *p*-amido-benzophenone with MeI at 100° . It decomposes at 181° (Doebner a. Weiss, B. 14, 1836; A. 210, 270; 217, 257).

Di-methyl-amido-benzophenone

$\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_4\text{NMe}_2$. [39°]. (330° - 340°). Obtained by heating benzoic acid with di-methyl-aniline and P_2O_5 at 185° (O. Fischer, A. 206, 88). Needles (from ligroin). Forms unstable salts. With nitrous acid it yields the oily nitroso-derivative $\text{C}_6\text{H}_5\text{CO.C}_6\text{H}_4(\text{NO})\text{NMe}_2$ (E. Bischoff, B. 22, 340).

Di-methyl-di-*p*-amido-benzophenone. Di-benzoyl derivative $\text{C}_6\text{H}_5\text{N}_2\text{O}$, i.e. $(\text{NMeBz.C}_6\text{H}_4)_2\text{CO}$. [102°]. Formed by heating tetra-methyl-di-amido-benzophenone with BzCl at 190° (Nathansohn a. Müller, B. 22, 1877). Small light-brown plates, sl. sol. cold, v. sol. hot, alcohol; sl. sol. benzene, almost insol. water and ether. Acids and alkalis at 100° do not saponify it.

Tri-methyl-di-amido-benzophenone

$\text{NHMe.C}_6\text{H}_4\text{CO.C}_6\text{H}_4\text{NMe}_2$. [156°]. Formed, together with di-methyl-aniline, by boiling penta-methyl-tri-amido-tri-phenyl-carbinol with HClAq (Wichelhaus, B. 19, 109). Nodular groups of needles (from alcohol).

Tetra-methyl-di-amido-benzophenone

$\text{NMe}_2\text{C}_6\text{H}_4\text{CO.C}_6\text{H}_4\text{NMe}_2$. [172°]. (above 360°) (Gräbe, B. 20, 3262).

Formation.—1. By passing COCl_2 into di-methyl-aniline (Michler, B. 9, 716, 1900).—2. By boiling hexa-methyl-tri-amido-tri-phenol-carbinol with HClAq (Wichelhaus, B. 19, 109).—3. From $\text{CCl}_4\text{SO}_2\text{Cl}$ and di-methyl-aniline (Michler a. Moro, B. 12, 1168).

Preparation.—By boiling auramine with aqueous HCl till decolourised, and ppg. with NH_3 .

Properties.—White plates (from dilute alcohol); insol. water, m. sol. alcohol, v. e. sol. warm benzene, v. sl. sol. ether.

Reactions.—1. Heating with ZnCl_2 and

NH₄Cl at 160° produces auramine (Fehrmann, *B.* 20, 2844).—2. Boiling HNO₃ (S.G. 1.48) gives insoluble yellow crystals of tetra-nitro-di-methyl-di-nitramido-benzophenone and tri-nitro-phenyl-methyl-nitramine [127°], soluble in alcohol (Romburgh, *R. T. C.* 6, 367).—3. Excess of bromine added to a solution of the base in glacial acetic acid gives the tetra-bromo-derivative (C₆H₂Br₄NMe₂)₂CO [172°] which crystallises in slender yellow needles from alcohol (Nathansohn a. Müller, *B.* 22, 1883).—4. Heating with aniline hydrochloride yields phenyl-auramine.—5. Combines with tri-nitro-benzene (2 mols.) forming a compound which crystallises in long reddish-violet needles [c. 100°]. With half the quantity of tri-nitro-benzene (1 mol.) it forms small deep-violet plates [123°].—6. Combines with *m*-di-nitro-benzene (2 mols.) forming a red crystalline compound.—7. Nitrous acid in the cold forms the nitroso-derivative NMe₂C₆H₄CO.C₆H₄(NOH).NMe₂ [159°] crystallising from alcohol in golden plates. This substance is a weak base, its solution in HClAq being ppd. by water. It gives Liebermann's reaction. Stannous chloride reduces it to the original tetra-methyl-di-amido-benzophenone. The nitroso-derivative forms the following salts: B'H₂Cl₂. Obtained by passing HCl into a solution of the nitroso-ketone in benzene.—B'C₆H₄(NO₂)₂OH. [152°]. Orange needles (from alcohol). The nitroso-ketone gives also a phenyl-hydrazide C₆H₂N₂O₂ [148°] (E. Bischoff, *B.* 21, 2452; 22, 337).—8. In presence of dehydrating agents, such as PCl₅ or AlCl₃, it condenses with secondary and tertiary bases. Thus with di-methyl-aniline it yields 'crystal violet' C(OH)(C₆H₄NMe₂)₃.

Salts.—B'H₂Cl₂: small radially-grouped prisms (from alcohol). Decomposed by water, with separation of the base (Fehrmann, *B.* 20, 2844).—B'H₂PtCl₆: yellow granules, insol. water, v. sl. sol. alcohol.—Picrate B'C₆H₄(NO₂)₂OH. [157°]. Small, purple, radially-grouped, prisms (from alcohol); insol. cold, v. sl. sol. hot, water; m. sol. alcohol.

Di-methyl-di-iodide B'Me₂I₂. [105°]. Light yellow plates (from alcohol), sl. sol. cold, v. sol. hot, water and alcohol. Split up at 150° into MeI and the base (Nathansohn a. Müller, *B.* 22, 1876).

Di-methylo-di-hydroxide B'Me₂(OH)₂. From the preceding and moist Ag₂O. Small yellow plates (from alcohol), quickly becoming dark and resinous (N. a. M.).

Oxim HON:C(C₆H₄NMe₂)₂: [233°]; colourless crystals (Munchmeyer, *B.* 19, 1852; 20, 1852).

Phenyl-hydrazide C₂H₅N₄ i.e. (NMe₂C₆H₄)₂C:N₂HPH. [175°]. Needles (from benzene-alcohol); m. sol. warm alcohol, v. sol. ether. Coloured green by acid oxidising agents (Ziegler, *B.* 20, 1111). Conc. H₂SO₄ gives a red colouration.

Imide (NMe₂C₆H₄)₂C:NH. *Auramine* base. [138°]. Formed by heating tetra-methyl-di-amido-benzophenone with NH₄Cl and ZnCl₂ at 150° to 160°. Formed also by treating a solution of tetra-methyl-di-amido-benzophenone in CS₂ with PCl₅ and subsequently adding ammonia (Caro a. Kern) (cf. *AURAMINE* in THORPE'S DICTIONARY OF APPLIED CHEMISTRY). Lemon-yellow

plates, insol. water and ether, m. sol. alcohol. Dilute HClAq readily converts it, even in the cold, into tetra-methyl-di-amido-benzophenone.

Reactions.—1. *Sodium-amalgam* reduces it (in alcoholic solution) to leucoauramine (C₆H₄NMe₂)₂CH.NH₂ [135°]. This substance forms colourless crystals which when treated with HOAc yield an intense blue solution (Græbe, *B.* 20, 3265).—2. H₂S in alcoholic solution at 60° forms tetra-methyl-di-amido-thio-benzophenone [164°].—3. CS₂ also forms (NMe₂C₆H₄)₂CS together with thiocyanic acid (Fehrmann, *B.* 20, 2847).

Salts.—B'HCl₂. *Auramine*. Yellow six-sided tables (from water at 70°). After expulsion of the water it melts (G.) or decomposes (F.) at 267°. M. sol. cold water, m. sol. alcohol. Boiling water converts it into tetra-methyl-di-amido-benzophenone. Dyes wool and silk greenish-yellow. Cotton prepared with tannin is also dyed yellow by auramine.—B'₂H₂PtCl₆: granules, insol. water; sl. sol. alcohol.—B'HI. [268°]. Minute columns.—B'HSCy aq. [200°–210°].—B'H₂P₂O₇. [194°]. Orange needles, sl. sol. water, m. sol. warm alcohol.—B'C₆H₄(NO₂)₂OH. [230°–236°]. Plates, insol. cold, v. sl. sol. hot, water; m. sol. hot alcohol.

Phenyl-imide (NMe₂C₆H₄)₂C:NPh. Formed by heating the hydrochloride of the imide (auramine) with aniline at 180° (F.). Small greyish-yellow radially grouped needles (from alcohol), decomposing at 80°. Insol. water and ether.—B'HI: reddish-crystalline mass, sol. water and alcohol. Its aqueous solution gradually decomposes, yielding aniline and tetra-methyl-di-amido-benzophenone.—B'₂H₂PtCl₆.—B'C₆H₄(NO₂)₂OH.

***p*-Tolyl-imide** (NMe₂C₆H₄)₂C:NC₆H₄Me. Resembles the phenyl-imide.—B'₂H₂PtCl₆.

Ethylene-di-amide C₆H₄N₄ i.e. (NMe₂C₆H₄)₂C<NH>CH₂. Formed by heating

auramine (hydrochloride) with ethylene-diamine at 100°–110° (Fehrmann, *B.* 20, 2855). Yellowish plates (from alcohol), insol. water, m. sol. warm alcohol. On treatment with HOAc or dilute HClAq it decomposes into ethylene-diamine and (NMe₂C₆H₄)₂CO. In alcoholic solution it is decomposed by H₂S into ethylene-diamine and (NMe₂C₆H₄)₂CS.—B'H₂Cl₂: yellow needles.—B'H₂PtCl₆: amorphous flakes, insol. water and ether, v. sol. warm alcohol.—B'2C₆H₄(NO₂)₂OH: flakes, v. sl. sol. water, v. sol. alcohol.

Tolylene-di-amide (NMe₂C₆H₄)₂C<NH>C₆H₄Me. Formed by heating the hydrochloride of the imide (auramine) with (1, 2, 4)-tolylene-diamine at 160°, and treating the product with ammonia. Small brown scales. In dilute acetic acid solution it dyes cotton, mordanted with tannin, reddish-brown. Dilute HClAq regenerates the original ketone.—B'H₂PtCl₆.—B'2C₆H₄(NO₂)₂OH.

Tetra-methyl-tri-amido-benzophenone C₆H₄N₃O i.e. NMe₂C₆H₄CO.C₆H₄(NH₂)(NMe₂) [82°]. Obtained by reducing nitro-tetra-methyl-di-amido-benzophenone (Nathansohn a. Müller, *B.* 22, 1884). Amorphous yellow powder, v. sol. hot, sl. sol. cold, alcohol and benzene, insol. ether.—B'C₆H₄(NO₂)₂OH: minute plates, v. sol.

hot alcohol, insoluble in benzene and ether.— $B_2H_3PtCl_6$: light-red crystalline pp., v. sol. warm alcohol, sl. sol. benzene, insol. water and ether.

METHYL- α -AMIDO- n -BUTYRIC ACID

$C_6H_{11}NO_2$, i.e. $CH_3CH_2CH(NHMe).CO_2H$. Formed by heating α -bromo-butyric acid with a concentrated solution of methylamine in sealed tubes at 100° . The product is boiled with baryta to expel NH_4Me , the Ba exactly ppd. by H_2SO_4 , and the HBr by Ag_2CO_3 (Duvillier, *A. Ch.* [5] 20, 188; *C. R.* 88, 425). Glistening leaflets (from alcohol), subliming above 120° without fusion. V. e. sol. water, m. sol. hot alcohol, insol. ether. Has a sweet taste. Feebly acid in reaction. By the prolonged action (several months) of cyanamide (1 mol.) in concentrated and slightly ammoniacal solution it is converted into butyro-creatinine $CH_3CH_2CH\langle\begin{smallmatrix} CO.NH \\ N(CH_3) \end{smallmatrix}\rangle C:NH$ which crystallises from alcohol in slender silky needles composed of small rectangular plates (Duvillier, *C. R.* 95, 456; *Bl.* [2] 39, 539).

Salts.— $HA'HCl$. [150°]. Badly defined crystals; sol. alcohol, insol. ether. Gives off HCl on fusion.— $H_2A'H_2PtCl_6$: orange-red crystals; v. sol. water and alcohol, insol. ether.— $H_2A'H_2PtCl_6$ 5aq. Formed at 0° .— $HA'HAuCl_4$ 4aq: transparent yellow prisms; sol. water, alcohol, and ether.—The nitrate and sulphate crystallise with difficulty in long needles.— CuA' 2aq: light-blue prisms; sol. alcohol.

Di-methyl- α -amido-butyric acid. *Anhydride of the methylo-hydroxide* $C_6H_{11}NO_2$, CH_3CH_2CH-CO

i.e. $(CH_3)_3N-\begin{smallmatrix} | \\ O \end{smallmatrix}$. *Tri-methyl- α -amido-butyro-betaïne*. Prepared by the action of bromo-butyric ether on an excess of tri-methylamine in alcoholic solution (Duvillier, *C. R.* 104, 1520). Large transparent crystals, containing aq, which they lose at 120° , becoming opaque; v. sol. water and alcohol, insol. ether. Has a bitter taste.— $B'HCl$. Uncrystallisable.— $B_2H_3PtCl_6$: orange prisms; sl. sol. alcohol. The aurochloride forms yellowish-white crystals.

METHYL-AMIDO-CAPROIC ACID v. METHYL-AMIDO-HEXOIC ACID.

METHYL-AMIDO-CHLORO- v. CHLORO-METHYL-AMIDO-.

METHYL-AMIDO-CYANURIC ACID v. CYANIC ACID.

METHYL-AMIDO-ETHANE SULPHONIC ACID $C_6H_{11}NSO_3$, i.e. $CH_3NHCH_2CH_2SO_3H$. *Methyl-taurine*. [242].

Formation.—From methyl-ethylene- ψ -thiourea and bromine-water (Gabriel, *B.* 22, 1148).

Preparation.—Silver chloro-ethane sulphate is heated with 3 times its weight of a solution of methylamine, saturated at 0° , for 5 hours at 120° . The product is boiled with baryta to expel excess of methylamine, freed from excess of baryta by H_2SO_4 , and evaporated to crystallisation. The crystals are washed with alcohol and recrystallised from water. The yield is 25 p.c. (E. Dittich, *J. pr.* [2] 18, 68).

Properties.—Transparent triclinic crystals. Sol. water, insol. alcohol and ether. Its aqueous solution is acid to litmus. Crystallises un-

altered from strong HCl . Does not form salts with acids and alkalis.

Reactions.—1. N_2O_5 forms isethionnic acid, $(HO)CH_2CH_2SO_3H$.—2. With cyanamide it combines to methyl-taurocyanamide or methyl-guanido-ethane sulphonic acid.

Di-methyl-amido-ethane sulphonic acid $NMe_2CH_2CH_2SO_3H$. Formed by heating di-methylamine β -chloro-ethane sulphate (20 g.) with aqueous (33 p.c.) dimethylamine (5 g.) at 160° for 10 hours (James, *J. pr.* [2] 31, 416; *C. J.* 47, 370). Large tables (from water); v. e. sol. water, insol. ether. Decomposes at 270° – 280° without fusion. Does not combine with HCl .

Anhydride of the methylo-hydroxide $\langle CH_2.NMe_2 \rangle O$. Formed by heating β -chloro-ethane sulphonic acid with aqueous tri-methylamine. Slender prisms (from water); v. sol. water, insol. alcohol and ether. Neutral in reaction. Tastes sweet. Not decomposed at 300° . Not acted upon by cyanamide. Baryta gives NMe_3 and isethionnic acid (James, *C. J.* 49, 489).

DI-METHYL-AMIDO-ETHYL ALCOHOL v. DI-METHYL-OXYETHYL-AMINE.

DI-METHYL-AMIDO-ETHYL-BENZENE v. DI-METHYL-AMIDO-PHENYL-ETHANE.

METHYL-AMIDO-ETHYL KETONE

$CH_3CO.CH(NH_2).CH_3$. Perhaps formed by reducing methyl nitroso-ethyl ketone, but if so it quickly changes to *s*-tetra-methyl-pyrazine.

METHYL-AMIDO-FORMIC ACID v. METHYL-CARBAMIC ACID.

METHYL- α -AMIDO- n -HEXOIC ACID

$C_8H_{17}NO_2$, i.e. $CH_3CH_2CH_2CH_2CH(NHMe).CO_2H$. *Methyl-amido-caproic acid*. S. 10.2 at 11° . Formed by heating α -bromo-hexoic acid (1 mol.) with aqueous methylamine (2 or 3 mols.) at 100° for several hours (Duvillier, *C. R.* 90, 822; *A. Ch.* [5] 29, 166). Silky needles (from water) or pearly plates (from alcohol). Sl. sol. cold alcohol, insol. ether. Neutral in reaction. Volatilises above 100° . Does not reduce silver or mercurous nitrate. Gives with ferric chloride an intense red colouration and a yellowish-brown pp. An equivalent quantity of cyanamide in cold concentrated solution containing a few drops of NH_3 forms in a few weeks crystals of 'hexoic

creatinine' $C_6H_9CH\langle\begin{smallmatrix} NMe.C:NH \\ CO.NH \end{smallmatrix}\rangle$. Sl. sol. cold water, v. sol. alcohol (Duvillier, *C. R.* 96, 1583; *Bl.* [2] 40, 307).— $HA'HCl$: transparent plates; v. sol. water and alcohol, insol. ether.— $H_2A'H_2PtCl_6$: orange crystals; v. e. sol. water, v. sol. alcohol, v. sl. sol. ether.—The aurochloride forms golden needles; the sulphate forms very indistinct crystals.— CuA' 2aq: blue scales, S. 1.

Di-methyl- α -amido-hexoic acid. *Methylo-hydroxide* $HO.NMe_2.C_6H_{13}.CO_2H$. Formed by heating leucine (1 mol.) derived from casein with aqueous KOH (3 mols.), and MeI (3 mols.). The resulting $INMe_2.C_6H_{13}.CO_2K$, which crystallises from alcohol in needles, being decomposed by moist Ag_2O (Körner a. Menozzi, *G.* 18, 853). Strongly alkaline. Decomposes at 120° – 180° into trimethylamine, an acid, $C_6H_{13}O_2$, and oxyhexoic acid. Forms the platinochloride

($\text{ONMe}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$), PtCl_4 , aurochloride $\text{Cl}_2\text{AuNMe}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ [168°], and periodide. The periodide forms lustrous green crystals, decomposed by H_2S , yielding $\text{INMe}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ [191°], crystallising in small prisms.

DI-METHYL-AMIDO-HYDROQUINONE
 $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{OH})_2$ [2:4:1]. *Di-methyl derivative* $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{OMe})_2$.

Methylo-iodide B'MeI . [202°]. Formed by heating the di-methyl derivative of amido-hydroquinone with methyl iodide (Bessler, *B.* 17, 2122). White needles; v. sol. water, sl. sol. absolute alcohol, nearly insol. benzene, chloroform, and ligroine.

Methylo-hydroxide B'McOH : soluble needles.

Methylo-chloride B'MeCl : white easily soluble needles [172°].—(B'MeCl), PtCl_4 : yellow crystalline pp.

TRI-METHYL-AMIDO-IMIDO-IMIDO-DI-PHENYL SULPHIDE. *Methylo-chloride*

$\text{C}_6\text{H}_4\text{N}_3\text{SCl}$ i.e. $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$. *Methylene-*
 NMe_2Cl

blue. Chloride of tetra-methyl-thionine.

Formation.—1. By the action of H_2S on an acid solution of nitroso-di-methyl-aniline and oxidation of the resulting leuco-methylene-blue. In this reaction di-methyl-*p*-phenylene-diamine is an intermediate product (Caro, *E. P.* 1877, 3751; Koch, *B.* 12, 593; Bernthsen, *A.* 230, 137).—2. By dissolving nitroso-di-methyl-aniline in H_2SO_4 (S.G. 1.4), treating with sulphide of zinc, and oxidising the resulting leuco-methylene-blue (Oehler, *G. P.* 1882, 24,125; Mühlhäuser, *D. P. J.* 262, 371).—3. By oxidation of di-methyl-*p*-phenylene diamine in presence of $\text{Na}_2\text{S}_2\text{O}_8$, and further oxidation of the resulting $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{S}\cdot\text{SO}_3\text{H}$ by chromic acid (Bernthsen).—4. By reducing the compound $\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{S}\cdot\text{SO}_3\text{H} \cdot 4\text{C}_6\text{H}_3(\text{NMe}_2)(\text{NH}_2)\text{SH}$ and oxidising a mixture of this mercaptan with di-methyl-aniline with HCl and $\text{K}_2\text{Cr}_2\text{O}_7$; the resulting 'soluble green' $\text{C}_6\text{H}_4\text{N}_3\text{S}$ or $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$ slowly changing in aqueous solution to 'methylene-blue' (Bernthsen, *A.* 251, 10).

Properties.—Minute dark-blue laminae (containing 3aq), v. sol. water and alcohol. Dyes mordanted cotton blue. Its aqueous solution is blue and not affected by HCl or ammonia. NaOH gives a violet colour and, when added in large quantity, a dirty violet pp. Conc. H_2SO_4 gives a yellowish-green solution, becoming blue on dilution. The aqueous solution is decolourised by H_2S or $\text{Na}_2\text{S}_2\text{O}_3$; the colour is restored even by feeble oxidising agents. Sodium hyposulphite $\text{Na}_2\text{S}_2\text{O}_3$ reduces it to the leuco-base. Fuming HClAq at 260° decomposes it, giving off H_2S . Boiling dilute HNO_3 oxidises it, forming H_2SO_4 . Boiling aqueous KOH forms 'thionel,' the anhydride of di-oxy-imido-di-phenyl sulphide $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{OH}) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$.

Salt.—($\text{C}_6\text{H}_4\text{N}_3\text{S}$), $\text{ZnCl}_2 \cdot \text{aq}$.

Formed by treating methylene-blue with moist Ag_2O . Amorphous, dark-blue mass; v. e. sol. water and alcohol, insol. ether.

Methylo-iodide $\text{C}_6\text{H}_4\text{N}_3\text{SI}$: bronzy needles (from hot water). The di-chloro-derivative of this iodide $\text{C}_6\text{H}_4\text{Cl}_2\text{N}_3\text{SI}$ is formed by successive treatment of di-chloro-di-methyl-*p*-phenylene-diamine $\text{C}_6\text{H}_2\text{Cl}_2(\text{NMe}_2)(\text{NH}_2)$ with H_2S , FeCl_3 , and KI (Möhlau, *B.* 19, 2012).

TRI-METHYL-AMIDO-IMIDO-IMIDO-DI-PHENYL-SULPHONE. *Methylo-iodide*

$\text{C}_6\text{H}_4\text{N}_3\text{SO}_2\text{I}$ i.e. $\text{N} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{SO}_2$. *Methyl-*
 NMe_2I

ene-azure. Formed, together with methylene violet, by boiling methylene blue with Ag_2O and a large quantity of water (Bernthsen, *A.* 230, 175). Slender needles with green lustre, sol. water, forming a violet solution from which it is ppd. by KI . Alkalis destroy the colour of the solution. The corresponding $\text{C}_6\text{H}_4\text{N}_3\text{SO}_2\text{Cl}$ crystallises in needles, v. e. sol. water. It dyes silk like methylene blue.

TETRA-METHYL-DI-AMIDO-IMIDO-DI-PHENYL METHANE v. *Imide of Tetra-methyl-DI-AMIDO-BENZOPHENONE.*

METHYL-DI-AMIDO-IMIDO-DI-PHENYL SULPHIDE $\text{C}_6\text{H}_4\text{N}_3\text{S}$ i.e. $\text{NMe} \begin{array}{c} \text{C}_6\text{H}_3(\text{NH}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$.

Methyl-di-amido-thio-diphenylamine. Formed by reduction of di-nitro-methyl-imido-di-phenyl sulphide with tin and HCl (Bernthsen, *A.* 230, 130). Insol. water, sol. ether. The dilute solution of its hydrochloride is coloured blue by FeCl_3 .— $\text{B'H}_2\text{Cl}$. Needles, v. sol. water, almost insol. HClAq .

Tetra-methyl-di-amido-imido-di-phenyl sulphide $\text{C}_6\text{H}_4\text{N}_4\text{S}$ i.e. $\text{NH} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$.

Leuco-methylene blue. Formed by treating methylene-blue with sodium hyposulphite $\text{Na}_2\text{S}_2\text{O}_3$ (Bernthsen, *A.* 230, 147). Needles (from alcohol), sl. sol. water, m. sol. cold alcohol. Gives an acetyl derivative, v. sol. alcohol, ether, and benzene. With MeI it forms $\text{NMe} \begin{array}{c} \text{C}_6\text{H}_3(\text{NMe}_2\text{I}) \\ \text{C}_6\text{H}_4 \end{array} \text{S}$ crystallising in plates, v. sl. sol. water and alcohol, insol. ether. Oxidised by air to methylene blue.— $\text{B'H}_2\text{ZnCl}_2$: prisms.

Di-methyl-amido-imido-phenyl disulphide
Methylo-chloride $\text{C}_6\text{H}_4\text{N}_3\text{S}_2\text{Cl}$ i.e.

$\text{NMe}_2\text{Cl} \begin{array}{c} \text{C}_6\text{H}_4 \\ \text{N-S} \end{array} \text{S}$. *Methylene red.* A by-pro-

duct in the manufacture of methylene-blue from di-methyl-*p*-phenylene-diamine and H_2S followed by FeCl_3 (Bernthsen, *A.* 230, 165; 251, 22; Koch, *B.* 12, 594). Small green glittering prisms (from alcohol), v. e. sol. water, insol. ether. Its aqueous and alcoholic solutions are purple. Not affected by HCl . Alkalis decompose it.—Zinc salt ($\text{C}_6\text{H}_4\text{N}_3\text{S}_2\text{Cl}$), $\text{ZnCl}_2 \cdot \text{aq}$.

DI-METHYL-AMIDO-JUGLONE v. **JUGLON.**
METHYL-AMIDO-MESITYLENE v. **METHYL-MESIDINE.**

METHYL-AMIDO-METHYL-BENZENES v. METHYL-PHENYL-METHYL-AMINES.**DI-METHYL-AMIDO-METHYL-PHEN-**

AZINE $C_6H_5(NMe_2) \begin{smallmatrix} \diagup N \diagdown \\ \diagdown N \diagup \end{smallmatrix} C_6H_5Me$. Formed by elimination of the NH_2 group from 'tolylene-red' by means of nitrous acid and alcohol (Bernthsen a. Schweitzer, *B.* 19, 2605). Red greenish-glistening needles or flat prisms. Has basic properties. Dissolves in dilute acids with a violet colour, in conc. H_2SO_4 with a reddish-brown, which on dilution first becomes green, then blue, and finally violet. Soluble in ether with a yellowish-red colour and yellow fluorescence. Sublimable.

Di-methyl-di-amido-methyl-phenazine

$C_{11}H_{12}N_4$, i.e. $C_6H_5(NMe_2) \begin{smallmatrix} \diagup N \diagdown \\ \diagdown N \diagup \end{smallmatrix} C_6H_5Me(NH_2)$.

Tolylene-red. Formed by oxidation of nitroso-oramido-dimethyl-aniline together with tolylene-diamine. The leuco-base has the formula $C_6H_5(NMe_2) \begin{smallmatrix} \diagup NH \diagdown \\ \diagdown NH \diagup \end{smallmatrix} C_6H_5Me(NH_2)$ (Bernthsen a. Schweitzer, *B.* 19, 2604).

DI-METHYL-AMIDO-METHYL-QUINOLINE TETRAHYDRIDE. *Di-methylo-di-iodide* $C_9H_9MeN.NMe_2Me_2I_2$. [171°]. Formed by heating (Py. 1)-amido-quinoline tetrahydride with methyl alcohol and MeI (Ziegler, *B.* 21, 862). Crystals.

METHYL-AMIDO-METHYL-THIAZOLE

$S.C(NHMe) \begin{smallmatrix} \diagup N \diagdown \\ \diagdown N \diagup \end{smallmatrix} CH=CMe$. *Methyl-thiazyl-*

amine. [42°]. Formed by the action of chloro-acetone on methyl-thio-urea (Traumann, *A.* 249, 44). Crystalline but extremely hygroscopic, m. sol. ether. Strongly alkaline in reaction. When heated with $HClAq$ in a sealed tube it yields methylamine. Br completely decomposes it.

Salts.— B^*HI : small white needles; melts, when anhydrous, at 136° (T).—Platinochloride: orange-yellow plates [167°].

Acetyl derivative $C_9H_9AcN_2S$. [110°]. White needles.

Methyl-amido-methyl-thiazole

$S.C(NH) \begin{smallmatrix} \diagup NMe \diagdown \\ \diagdown NMe \diagup \end{smallmatrix} CH=CMe$. *Imido-di-methyl-thiazole*.

[47.5°]. Formed from chloro-acetone by treatment with ammonium sulpho-cyanide (Tcherniak a. Norton, *B.* 16, 345) and heating with MeI the resulting amido-methyl-thiazole (so-called propinine sulphocyanide) (Hantzsch a. Weber, *B.* 20, 3122, 3336). Crystalline, but very hygroscopic. Strongly alkaline. When heated with $HClAq$ in sealed tubes it yields ammonia. Conc. $KOHAq$ has no action.

Salts.— B^*HI aq. Tables [164°].—Platinochloride: orange tables [193°].

Acetyl derivative $C_9H_9AcN_2S$. [113°]. White needles (containing 6 aq.).

Di-methyl-amido-methyl-thiazole $C_9H_9N_2S$ $S.C(NMe) \begin{smallmatrix} \diagup NMe \diagdown \\ \diagdown NMe \diagup \end{smallmatrix} CH=CMe$. *Methyl-imido-dimethyl-*

thiazole. [96°]. Formed by adding conc. $KOHAq$ to its hydro-iodide (Hantzsch a. Weber, *B.* 20, 3123). White needles, sol. alcohol, water, and

ether. Bromine reacts with formation of $C_9MeBr(NMe_2)SN$ [174°].

Salts.— B^*HI aq. [54°]. From MeI and $C_9MeH(NHMe)SN$. Melts at 156° when anhydrous.

Methylo-iodide B^*MeI . [85°]. White needles, v. e. sol. water and alcohol.

DI-METHYL-AMIDO-NAPHTHOIC ACID $C_{10}H_7(NMe_2)(CO_2H)$ [1.4]. [165°]. Formed by heating di-methyl-(a)-naphthylamine with $COCl_2$ at 70° for 4 hours (Friedländer, *B.* 21, 3126). Needles (from dilute alcohol), sol. dilute acids and alkalis. When acted upon by diazo-compounds the azo-group displaces the CO_2H .— $(HA)_2H_2PtCl_6$: yellow needles.

DI-METHYL-AMIDO-NAPHTHO-PHEN-

AZINE $C_{10}H_7 \begin{smallmatrix} \diagup N \diagdown \\ \diagdown N \diagup \end{smallmatrix} C_6H_5.NMe_2$. *Di-methyl-*

naphth-eurhodine. [205°]. Formed from nitroso-di-methyl-aniline hydrochloride, (β)-naphthylamine, and $AcHO$ (Witt, *B.* 21, 720). Rhombic tables (from toluene or xylene), red by transmitted, and red or green, according to the faces, by reflected light; sol. alcohol, ether, and benzene, forming yellow solutions with yellow fluorescence. Is volatile with slight decomposition, and sublimes readily in woolly flocks. The violet-red solution in conc. H_2SO_4 becomes successively black, green, grey, and blue-violet on dilution. The salts crystallise readily, have a bronzy lustre, and are dissociated by water. $AcHO$ dissolves it with red-violet colour. Conc. HNO_3 with violet, soon becoming bright yellow and depositing the nitro-compound.

METHYL-AMIDO-NAPHTHOQUINONE

$C_{11}H_9NO_2$ i.e. $C_{10}H_7O_2(NHMe)$. [232°]. Formed by adding a solution of methylamine acetate to an alcoholic solution of (a)-naphthoquinone, evaporating nearly to dryness, adding water, and crystallising the pp. from alcohol (Plimpton, *C. J.* 37, 639). Glittering red needles, v. sol. alcohol. Aqueous SO_2 at 150° forms an unstable colourless reduction-product.

Di-methyl-amido-naphthoquinone $C_{11}H_9O_2(NMe_2)$. [118°]. From (a)-naphthoquinone and di-methyl-amine in alcoholic solution (Plimpton). Red needles.

DI-METHYL-AMIDO-NAPHTHYLAMINE v. NAPHTHYLENE-DI-METHYL-DIAMINE.**TETRA-METHYL-DI-AMIDO-DI-NAPHTHYL-PHENYL-METHANE**

$Ph.CH(C_6H_4NMe_2)_2$. [189°]. Formed by the action of benzoic aldehyde on di-methyl-(a)-naphthylamine in presence of $ZnCl_2$ (Friedländer, *B.* 21, 3128). Colourless crystals, v. sol. $HOAc$, benzene, CS_2 , and dilute mineral acids, sl. sol. alcohol, ether. Does not yield a colour on oxidation.

Hexa-methyl-tri-amido-di-naphthyl-phenyl-methane $HC(C_6H_4NMe_2)_3$. [179°]. Formed by condensing di-methyl-p-amido-benzoic aldehyde with di-methyl-(a)-naphthylamine in presence of $ZnCl_2$ (Friedländer, *B.* 21, 3129). White needles. Does not yield a colour on oxidation.

METHYL-AMIDO-NITRO-compounds v. NITRO-METHYL-AMIDO-compounds.

METHYL-AMIDO-OKY-compounds v. OKY-METHYL-AMIDO-compounds.

METHYL-AMIDO-PEREZONE v. **METHYL-AMIDO-PITZARHOIC ACID.**

METHYL-o-AMIDO-PHENOL: *Methyl derivative* C_6H_4NO i.e. $C_6H_4(NHMe)(OMe)$ [1:2]. *Methyl anisidine.* (219°). Formed by mixing the methyl derivative of o-amido-phenol with MeI at 0° (Mühlhäuser, A. 207, 247). Oil.— $B''H_2PtCl_6$: short yellow prisms, m. sol. water.

Methyl-p-amido-phenol. *Ethyl derivative* C_6H_4NO i.e. $C_6H_4(NHMe)(OEt)$ [1:4]. (251°). Formed by heating the ethyl derivative of p-oxy-phenyl-amido-acetic acid at 260° (Bischhoff a. Nastvogel, B. 22, 1789). Sl. sol. water, v. sol. alcohol and ether.— $B'HCl$: needles.

Di-methyl-o-amido-phenol C_6H_4NO i.e. $C_6H_4(NMe_2)(OH)$ [1:2]. [45°]. Obtained, together with MeCl by the dry distillation of the methylo-chloride (Griess, B. 13, 248). Small white prisms, v. sl. sol. hot water, v. sol. alcohol, ether, HOAc, and aqueous KOH. $FeCl_3$ gives a reddish-violet colour. Its hydrochloride is gummy.

Methylo-hydroxide $C_6H_4(NMe_2OH)(OH)$ or $C_6H_4 \begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ aq. Prepared by the action of MeI and KOH on a solution of o-amido-phenol in methyl alcohol (Griess, B. 13, 246). Prisms,

which become $C_6H_4 \begin{smallmatrix} O \\ | \\ NMe_3 \end{smallmatrix}$ at 105°. V. sol. water and alcohol, insol. ether. Has an intensely bitter taste. On distillation it is converted into $C_6H_4(NMe_2)(OMe)$. With acids it forms the following salts:— $C_6H_4(NMe_2I)(OH)$ aq.: white soluble prisms. Its solution, neutralised by ammonia, deposits sparingly soluble needles or

prisms of $C_6H_4(NMe_2I)(OH)C_6H_4 \begin{smallmatrix} O \\ | \\ NMe_3 \end{smallmatrix}$.— $C_6H_4(NMe_2Cl)(OH)2$ 2aq.: long soluble prisms.— $(C_6H_4(NMe_2Cl)(OH))_2PtCl_6$: yellowish-red needles, sl. sol. cold water.—The periodide forms brown insoluble leaflets.—The nitroprusside $(C_6H_4NO)_2H_2FeCy_2NO$ forms crystals, sl. sol. cold water.

Methyl-derivative C_6H_4NO i.e. $C_6H_4(NMe_2)(OMe)$ [1:2]. (211°). S.G. \approx 1.016. Formed by an isomeric change by distilling

$C_6H_4 \begin{smallmatrix} O \\ | \\ NMe_3 \end{smallmatrix}$ (Griess, B. 13, 248). Formed also from MeI and the methyl derivative of o-amido-phenol (Mühlhäuser, A. 207, 248). Colourless liquid, with burning taste.— $B''H_2PtCl_6$: sparingly soluble golden-yellow prisms.

Methylo-iodide of the methyl derivative $C_6H_4(NMe_2I)(OMe)$. From the preceding and MeI. Long white needles (G.) or tables (M.), sol. hot water and hot alcohol. With moist Ag_2O it yields a strongly alkaline hydroxide. It also yields a platinumchloride $(C_6H_4(NMe_2Cl)(OMe))_2PtCl_6$, which crystallises in sparingly soluble yellow plates or tables.

Di-methyl-m-amido-phenol. $C_6H_4(OH)NMe_2$. Prepared by fusing di-methyl-amido-benzene m-sulphonic acid with KOH. Also by heating resorcin with di-methyl-amine under pressure.

Ethyl ether $C_6H_4(OEt)(NMe_2)$ [1:3]. (247°). Obtained by boiling a solution of m-amido-phenol and methyl iodide and slowly running

in the calculated quantity of potash. The base is distilled over with steam (P. Wagner, J. pr. [2] 32, 77; Baur a. Stadel, B. 16, 82). Converted by HCl and amyl nitrite into the nitroso-compound $C_6H_4(NO)(OEt)(NMe_2)$.

Di-methyl-p-amido-phenol. *Methylo-hydroxide.* The anhydride $C_6H_4 \begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$

is formed by the action of MeI and conc. KOHAq upon p-amido-phenol in the cold (Griess, B. 13, 250). Prisms or plates. Changes on distillation into the isomeric $C_6H_4(NMe_2)(OMe)$ [48°].

Methyl derivative $C_6H_4(NMe_2)(OMe)$ [1:4]. [48°]. Formed as above (Griess, B. 13, 249). Prisms or plates (from alcohol).

Methylo-iodide $C_6H_4(NMe_2I)(OMe)$. Formed by the action of MeI on either the methyl derivative or the methylo-hydroxide. Tables or plates. With moist Ag_2O it yields the methylo-hydroxide as a strongly alkaline mass. The platinumchloride $(C_6H_4(NMe_2Cl)(OMe))_2PtCl_6$ forms small yellow prisms, sl. sol. water.

Di-methyl-di-amido-phenol. *Anhydride of the methylo-hydroxide* $C_6H_4N_2O$ i.e.

$C_6H_4(NH_2) \begin{smallmatrix} O \\ | \\ NMe_2 \end{smallmatrix}$ [4:2]. Prepared by reduction

of the methylo-hydroxide of nitro-di-methyl-amido-phenol with tin and HCl (Griess, B. 13, 648).— $B''H_2Cl_2$ 4aq.: very soluble white plates.— $B''H_2PtCl_6$ 2aq.: small prisms, sl. sol. water.

TETRA-METHYL-DI-p-AMIDO-DIPHENYL $NMe_2.C_6H_4.C_6H_4.NMe_2$. *Tetra-methyl-benzidine.* [195°]. (above 360°).

Formation.—1. By heating di-methyl-aniline (1 pt.) with H_2SO_4 (4 pts.) at 200°. Formed also in small quantity by oxidising di-methyl-aniline by boiling with PbO_2 and dilute H_2SO_4 (Michler a. Pattinson, B. 14, 2161; 17, 115).—2. By heating di-methyl-aniline with $AlCl_3$ in presence of air (Giraud, Bl. [3] 1, 692).—3. By methylation of benzidine.

Properties.—Colourless needles; sol. hot, sl. sol. cold, alcohol. Not volatile with steam. Gives a green colouration with $FeCl_3$ or CrO_3 .— $B''H_2Cl_2$: sparingly soluble needles.— $B''H_2Br_2$: needles.— $B''H_2I_2$: white needles.— $B''H_2PtCl_6$:

Methylo-iodide $B''MeI$. [263°]. Needles, sl. sol. water and alcohol. Loses MeI when distilled with sodg-lime.

Methylo-chloride $B''MeCl$. [228°]. Crystals, very soluble in water and alcohol.— $B''McIHPtCl_6$: yellow pp.

Tetra-methyl-op-di-amido-diphenyl [2:1] $NMe_2.C_6H_4.C_6H_4.NMe_2$ [1:4]. *Tetra-methyl-diphenylene.* [52°]. (333°-345°). Formed by heating diphenylene hydrochloride with MeOH in sealed tubes at 180° (Reuland, B. 22, 8015). Prisms. Gives with platinum chloride an unstable pp. Chloranil produces a blue colouration.— $B''C_6H_4(NO_2)_2.OH$. [200°]. Red needles.

Methylo-iodide $B''MeI$. [184°]. Needles, v. sol. water, alcohol, and ether.

Di-methylo-di-iodide $B''MeI_2$. [196°]. Crystalline, v. sol. water and alcohol.

Tetra-methyl-tetra-amido-diphenyl $NMe_2.C_6H_4(NH_2).C_6H_4(NH_2).NMe_2$. *Tetra-methyl-benzidine.* [168°]. Prepared by reduction of di-

nitro-tetra-methyl-diphenyl (Michler & Pattinson, *B. 14*, 2165; 17, 118). White silvery plates, v. sol. hot alcohol, sl. sol. cold alcohol, insol. water. FeCl_3 gives a violet colouration. $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 produce a brownish-red colour.— $\text{B}''\text{H}_2\text{Cl}_2$ (dried at 110°): sparingly soluble colourless needles.— $\text{B}''\text{H}_2\text{I}_2$: sparingly soluble needles.— $\text{B}''\text{H}_2\text{PtCl}_6$: yellow pp.

Methyl- α -amido-phenyl-acetic acid $\text{C}_6\text{H}_4\text{NO}_2$, i.e. $\text{C}_6\text{H}_3\text{CH}(\text{NHMe})\text{CO}_2\text{H}$. Formed from the nitrile of mandelic acid $\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{CN}$ by digesting with alcoholic NH_4Me at 70° , and decomposing the resulting nitrile with HCl (Tiemann & Piest, *B. 14*, 1982). Slender needles (from hot water). Sublimes at 274° . Sl. sol. cold water, insol. alcohol and ether.

Amide $\text{C}_6\text{H}_3\text{CH}(\text{NHMe})\text{CONH}_2$. [155°]. Slender needles.— $\text{B}''\text{HCl}$. Needles, sol. alcohol, insol. ether.

DI-METHYL-AMIDO-PHENYL- ω -AMIDO-CRESOL. *Methyl derivative* [4:1] $\text{NMe}_2\text{C}_6\text{H}_3\text{NHCH}_2\text{C}_6\text{H}_4\text{OMe}$ [1:4]. [104°]. Formed by reducing $\text{NMe}_2\text{C}_6\text{H}_3\text{N}:\text{CHC}_6\text{H}_4\text{OMe}$ with sodium (Steinhart, *A. 241*, 843). Light green plates; v. sol. acids, forming red solutions. Its alcoholic solution decomposes rapidly.

DI-METHYL-AMIDO-DI-PHENYL-AMINE $\text{Me}_2\text{N.C}_6\text{H}_4\text{.NHPh}$. [130°]. One of the products formed by the action of phenyl-hydrazine on nitroso-dimethylamine in an alcoholic solution (O. Fischer, *B. 21*, 2612). White needles (from petroleum-ether), v. sol. dilute HCl , m. sol. dilute SO_2 . Gives a blue colouration with FeCl_3 . Dissolves with a red colour in nitric acid.

Nitrosamine $\text{C}_{11}\text{H}_{13}\text{N}_3\text{O}$. [116°]. Yellow needles (from alcohol).

Tetra-methyl-di-amido-diphenyl-amine ($\text{NMe}_2\text{C}_6\text{H}_4)_2\text{NH}$. [119°]. Obtained by oxidising a mixture of di-methyl-aniline (1 mol.) and di-methyl-*p*-phenylene-diamine (1 mol.) and reducing the resulting 'dimethyl-phenylene green' (Bindscheider, *B. 16*, 864). Yellowish dimetric tabs.

Hexa-methyl-tri-amido-triphenylamine.

Tri-methylo-trichloride ($\text{NMe}_2\text{Cl.C}_6\text{H}_4)_3\text{N}$. Obtained by heating tri-amido-tri-phenyl-amine hydrochloride with MeOH at 190° (Heydrich, *B. 19*, 758). White needles.—($\text{NMe}_2\text{Cl.C}_6\text{H}_4)_3\text{N} \cdot 8\text{PtCl}_6$.

DI-METHYL-AMIDO-PHENYL-BENZYL-AMINE $\text{NMe}_2\text{C}_6\text{H}_4\text{.NHCH}_2\text{Ph}$. [48°]. Obtained by reducing benzylidene-di-methyl-phenylene-diamine [101°] with sodium-amalgam (Kohler, *A. 241*, 861). Yellowish plates, v. sol. dilute mineral acids, alcohol, ether, benzene, and petroleum ether.

Nitrosamine $\text{NMe}_2\text{C}_6\text{H}_4\text{N(NO).CH}_2\text{Ph}$. [128°]. Slender yellow needles, sol. alcohol.

DI-METHYL-AMIDO-DI-PHENYL-CARBINOL $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH).C}_6\text{H}_4$. *Di-methyl-amido-di-phenyl-carbinol*. [70°]. Formed by reducing di-methyl-amido-benzophenone with sodium-amalgam, or by the action of benzoic aldehyde on di-methyl-aniline (Albrecht, *B. 21*, 3292). Thin white needles, insol. water, v. e. sol. ordinary solvents, sl. sol. petroleum ether.

Di-methyl-di-amido-di-phenyl-carbinol $\text{NMe}_2\text{C}_6\text{H}_4\text{CH(OH).C}_6\text{H}_4\text{.NH}_2$. [165°]. Formed by carefully reducing *p*-nitro-di-methyl-amido-di-phenyl-carbinol with zinc-dust and HCl (Al-

brecht, *B. 21*, 3295). Dissolves in HOAc with blue colouration. Crystallises from benzene in needles containing benzene and melting at 142° . Gives off water (1 mol.) when heated above its melting-point. Boiling with zinc-dust and HCl reduces it to di-methyl-diamido-di-phenyl-methane [93°].

Tetra-methyl-di-amido-di-phenyl-carbinol $\text{C}_{17}\text{H}_{22}\text{N}_2\text{O}$ i.e. ($\text{NMe}_2\text{C}_6\text{H}_4$)₂ CH(OH) . [96°]. Obtained by reducing tetra-methyl-di-amido-benzophenone in hot alcoholic solution with sodium-amalgam (Michler & Dupertuis, *B. 9*, 1899; Nathansohn & Müller, *B. 22*, 1879). Colourless triclinic prisms, v. sol. alcohol, HOAc , benzene, and ether. Its solution in HOAc is blue, the benzene solution is colourless.

Salts.— $\text{B}''\text{HCl}$. Formed by passing HCl into a solution of the base in ether. Small colourless slender radially grouped needles. In air it turns blue and deliquesces. It is dissociated by water.— $\text{B}''\text{H}_2\text{PtCl}_6$: minute yellow needles, v. sol. hot alcohol.— $\text{B}''\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$: dark-green crystalline mass, v. sol. hot alcohol, sl. sol. benzene, insol. ether.

Di-methylo-di-iodide $\text{B}''\text{Me}_2\text{I}_2$. [195°]. Small plates (from alcohol), sl. sol. cold, v. sol. hot, alcohol and water, insol. benzene and ether.

Tetra-methyl-di-amido-tri-phenyl-carbinol $\text{C}_{17}\text{H}_{22}\text{N}_2\text{O}$ i.e. $\text{C}_6\text{H}_5\text{C(OH)(C}_6\text{H}_4\text{NMe}_2)_2$. [132°]. *Malachite green*. *Benzaldehyde green*.

Formation.—1. By the action of dimethyl-aniline on benzotrichloride in presence of a metallic chloride (Doebner, *B. 11*, 1238; 13, 2222).—2. By the oxidation of a slightly acid solution of tetra-methyl-di-amido-tri-phenyl-methane with MnO_2 or PbO_2 (E. & O. Fischer, *B. 12*, 796), or with tetra-chloro-quinone (O. Fischer, *A. 206*, 130).—3. By heating di-methyl-aniline (4 pts.) with BzCl (2 pts.) and ZnCl_2 (3 pts.) (Fischer).

Preparation.—1. From di-methyl-aniline (2 mols.), ZnCl_2 (half its weight), sand, and benzo-trichloride at 130° . The product is distilled with steam and the dye ppd. from the aqueous residue by NaCl . The pp. is the zinc double chloride, which may be converted by KOH into the base. This is converted into the oxalate which may be purified by crystallisation from water and then decomposed by ammonia (Doebner, *A. 217*, 250).—2. By heating benzoic aldehyde (40 g.) with dimethylaniline (100 g.) and 93 p.c. alcohol (40 g.) over a water-bath. POCl_3 (55 g.) is then added gradually, and when cool the mass is extracted with warm water and the base ppd. with NaOH . The yield is nearly theoretical (Nencki, *M. 9*, 1148).—3. By heating benzoic aldehyde with ZnCl_2 and di-methyl-aniline, and oxidising the resulting leuco-base with PbO_2 (Mühlhäuser, *D. P. J.* 263, 249).

Properties.—Nearly colourless cubes. Insol. water. V. sol. alcohol forming a green solution. When freshly ppd. it is v. sol. ether, but when crystalline it is sl. sol. ether; m. sol. CS_2 , acetone, benzene or light petroleum.

Reactions.—1. HClAq at 250° splits it into dimethylaniline and di-methyl-*p*-amido-benzophenone.—2. On reduction it yields leuco-malachite green (tetra-methyl-di-amido-tri-phenyl-methane) [101°].—3. Fuming HNO_3 in HOAc forms an amorphous hexa-nitro-derivative.

Salts.—The salts of organic acids and

neutral salts of mineral acids are green and dye emerald-green. They are v. sol. water, the oxalate being m. sol. water and the picrate sl. sol. water. Concentrated mineral acids turn the solutions orange, forming acid salts. Diluting with water restores the green colour. In the cold, dilute acids dissolve the base, forming a nearly colourless solution, which turns deep green when heated, a molecule of water being probably split off. Thus the hydrochloride becomes

($\text{C}_{22}\text{H}_{21}\text{N}_2\text{HCl}$) $_2$ (ZnCl_2) $_2$ 2aq. [c. 180°]. *Malachite green*. Thick, dark-green prisms, sol. water (Fischer, B. 14, 2520).— $\text{C}_{22}\text{H}_{21}\text{N}_2\text{ZnCl}_2$ aq.— $\text{C}_{22}\text{H}_{21}\text{N}_2\text{H}_2\text{SO}_4$ — $\text{C}_{22}\text{H}_{21}\text{N}_2\text{H}_2\text{SO}_4$ aq.: lustrous green prisms.—($\text{C}_{22}\text{H}_{21}\text{N}_2$) $_2$ 3 $\text{H}_2\text{C}_6\text{O}_4$. *Malachite green*. Large green tables, sol. water and alcohol.—Picrates $\text{C}_{22}\text{H}_{21}\text{N}_2\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$. Golden needles (from benzene), insol. water.— $\text{C}_{22}\text{H}_{21}\text{N}_2\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$: golden needles.

Di-methyl-di-iodide $\text{C}_{22}\text{H}_{21}\text{NMe}_2\text{I}_2$ aq. [172°]. Formed by heating the base with MeI and MeOH at 100° (Doebner). Green plates, sl. sol. alcohol, ether, benzene, CS_2 , and cold water, v. sol. hot water. The same compound is obtained by heating di-*p*-amido-tri-phenyl-carbinol with MeI and alcohol at 120° (Doebner, B. 15, 236).

Ethyl derivative $\text{C}_{22}\text{H}_{21}\text{C}(\text{OEt})(\text{C}_6\text{H}_4\text{NMe}_2)_2$. [162°]. From the base by heating with alcohol at 110° (O. Fischer, B. 12, 1686).

Sulphonic acid $\text{C}_{22}\text{H}_{21}(\text{SO}_3\text{H})\text{N}_2\text{O}$. Green needles with reddish-brown lustre, v. a. sol. hot water, forming a green solution.— NaA .— MgA_2 4aq.— CaA , 3aq.

Derivatives v. Bromo-, Chloro-, Nitro-, and Oxy-tetra-methyl-di-amido-tri-phenyl-carbinol.

*Tetra-methyl-*ppp*-trif-amido-tri-phenyl-carbinol* $\text{C}_{22}\text{H}_{21}\text{N}_3\text{O}$ i.e. $\text{NH}_2\text{C}_6\text{H}_4\text{C}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$. [191°]. Formed by oxidation of the acetyl derivative of the leuco-base (tetra-methyl-di-*p*-amido-*o*-amido-tri-phenyl-methane) with lead peroxide and dilute H_2SO_4 (Fischer a. Schmidt, B. 17, 1892). Glistening prisms (from ether). The salts are soluble in water with a bluish-green colour.

*Tetra-methyl-tri-*p*-amido-tri-phenyl-carbinol* $\text{NH}_2\text{C}_6\text{H}_4\text{CH}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$. *Tetra-methyl-*pararosaniline**. Obtained by oxidising the acetyl derivative of tetra-methyl-tri-*p*-amido-tri-phenyl-methane with PbO_2 , and boiling the resulting acetyl derivative with HCl (O. Fischer a. G. Körner, B. 16, 2904). Small crystals (from ether).

Penta-methyl-tri-amido-tri-phenyl-carbinol $\text{C}_{22}\text{H}_{21}\text{N}_3\text{O}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OH})\text{C}_6\text{H}_4\text{NHMe}$. *Methyl-violet*. [180°]. Prepared by oxidising dimethylaniline with SnCl_4 , with ICl, with HgCl_2 , and KClO_3 , with KClO_4 , and CuSO_4 , or with NaCl and $\text{Cu}(\text{NO}_3)_2$ (Lauth, *Rép. Chim. app.* 1861, 345; Poirrier a. Chappat, *Bl.* 2, 6, 503; Hofmann, B. 6, 357). Formed also by heating dimethyl-aniline with $\text{C}_2\text{H}_5\text{SO}_2\text{Cl}$ at 100° (Hassencamp, B. 12, 1275), and, together with formic aldehyde, by shaking hexa-methyl-tri-amido-tri-phenyl-carbinol with MnO_2 and dilute H_2SO_4 (E. a. O.

Fischer, B. 11, 2097). Commercial methyl-violet may be freed from admixed hexa-methyl-tri-amido-tri-phenyl-carbinol by boiling with ligroin (Wichelhaus, B. 18, 2006; 19, 108). Methyl-violet occurs in Hofmann's violet.

Properties.—Brown powder, melting under water. Insol. water, ether, and ligroin. Its alcoholic solution is violet. Its solution in HCl is reddish-violet, and is ppd. by NaOH, but not by ammonia. Reduced by ammonium sulphide to its leuco-base. Tin and HCl reduce it, forming a substance melting at 155°. Boiling HCl aq. splits it up into di-methyl-aniline and tri-methyl-di-amido-benzophenone.

Salts.—Chloride $\text{C}_{22}\text{H}_{21}\text{N}_3\text{Cl}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OH})\text{C}_6\text{H}_4\text{NMe}_2\text{HCl}$. Amorphous mass,

with green metallic lustre. Its aqueous solution is violet, but on adding HCl it becomes first green, then deep yellowish-brown. It dissolves in alcohol. Conc. H_2SO_4 forms a yellow solution, which on dilution changes through greenish-blue to violet. It dyes silk, wool, and mordanted cotton violet.— $\text{C}_{22}\text{H}_{21}\text{N}_3\text{I}$: minute needles.

Picrate $\text{C}_{22}\text{H}_{21}\text{N}_3\text{C}_6\text{H}_4(\text{NO}_2)_3(\text{OH})$. Bronzed needles (from alcohol).

Acetyl derivative. Acetate $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OAc})\text{C}_6\text{H}_4\text{NMe}_2\text{OAc}$. [225°]. From

methyl-violet, Ac_2O , and NaOAc (O. Fischer a. G. Körner, B. 16, 2906).

Hexa-methyl-tri-amido-tri-phenyl-carbinol $\text{C}_{22}\text{H}_{21}\text{N}_3\text{O}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{COH}$. *Crystal violet*. *Hexa-methyl-*para*-rosaniline*. [195°].

Formation.—1. Together with its methyl-iodide, by heating methyl-violet with MeI and MeOH at 120° (Hofmann, B. 6, 363).—2. By the action of dimethylaniline on tetra-methyl-di-amido-benzophenone in presence of dehydrating agents (Kern a. Caro). In this reaction tetra-methyl-di-amido-thio-benzophenone may also be used.—3. By the action of COCl_2 , of ClCO_2Et , or of $\text{ClCO}_2\text{CCl}_3$, in presence of ZnCl_2 , on dimethylaniline.—4. By condensation of tetra-methyl-di-amido-di-phenyl carbinol with dimethylaniline and oxidation of the resulting leuco-base.—5. By gradually adding tetra-chloroquinone (1 pt.) to dimethylaniline (2 pts.), and heating the product to 65° (Meister, Lucius, a. Brüning, B. 13, 212, 2100; Wichelhaus, B. 16, 2005). Perhaps the substance formed in this case is wholly or partially the penta-methyl compound.—6. By the action of COCl_2 , or of ClCO_2Et on dimethylaniline in presence of AlCl $_3$ (Hofmann, B. 18, 767; Wichelhaus, B. 19, 109).

Properties.—Dark reddish-violet monoclinic tables. Needles containing benzene (from benzene). Insol. water, sol. ether, acetone, and ligroin, sl. sol. alcohol, v. a. sol. chloroform and benzene. Boiling HCl aq. splits it up into dimethylaniline and tetra-methyl-di-amido-benzophenone. Aqueous ammonium sulphide reduces it to hexa-methyl-tri-amido-tri-phenyl-methane.

Salts.—Chloride $\text{C}_{22}\text{H}_{21}\text{N}_3\text{Cl}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C} \begin{array}{l} \text{C}_6\text{H}_4 \\ \text{NMe}_2\text{Cl} \end{array}$. Hexagonal crystals,

with greenish-brown lustre (Wada, B. 18, 768). Sol. alcohol. Forms a violet solution in water, which on adding HCl becomes first blue, then green, and finally yellow. NaOH gives a violet pp. Conc. H_2SO_4 forms a yellow solution,

changed on dilution through green and blue to violet. Dyes silk, wool, and mordanted cotton bluish-violet. — $C_{22}H_{20}N_2Cl$ 84g: crystals, with bronze lustre. — $(C_{22}H_{20}N_2Cl)_3PtCl_6$: brick-red crystalline pp., decomposed by water. — $C_{22}H_{20}N_2OHL$: green crystals. At 100° it gives off MeI, becoming the iodide of penta-methyl-tri-amido-tri-phenyl-carbinol. — Picrate $C_{22}H_{20}N_2O_2C_6H_4(NO_2)_3OH$: yellowish-green prisms, with copper lustre.

Methylo-iodide $C_{22}H_{20}N_2I$ MeI. From pararos-aniline, MeI, and MeOH at 115° (Hofmann, B. 6, 365).

TETRA-METHYL-DIAMIDO-DIPHENYL-CUMYL-METHANE $C_{22}H_{22}N_2$, i.e. $(NMe_2.C_6H_4).CH.C_6H_4.C_6H_5$. Prepared by heating cuminic aldehyde with dimethylaniline and $ZnCl_2$ to 120° ; the yield is about 80 p.c. On oxidation it gives a dye-stuff closely resembling malachite green.

Salts. — $B''H_2Cl_2$: white crystalline powder. — $B''(C_6H_4(NO_2)_3OH)$: green crystals, $[156^\circ]$, explodes at 220° . — $B''H_2Cl_2PtCl_6$: yellow crystals.

Methylo-iodide $B''MeI_2$: white needles, $[220^\circ]$. Sl. sol. cold, v. sol. hot, water (Zeigler, B. 13, 786).

DI-METHYL-AMIDO-PHENYLENE-DIPHENYL-DIKETONE $NMe_2.C_6H_4(CO.C_6H_4)_2$, $[55^\circ]$. From dimethylaniline and $BaCl$ at 180° . Crystals, v. sol. alcohol and ether.

Hexa-methyl-tri-amido-phenylene-diphenyl-diketone $C_{22}H_{22}N_6$, i.e. $NMe_2.C_6H_4(CO.C_6H_4.NMe_2)_2$, $[122^\circ]$. From boiling di-methyl-aniline and $COCl_2$ (Michler, B. 9, 716; Michler a. Dupertuis, B. 9, 1899). Monoclinic crystals; $a:b:c = .587:1:1.14$; $\beta = 125^\circ 18'$.

METHYL-AMIDO-PHENYL-ETHANE. *Nitroso-derivative* $[4:1]Et.C_6H_4.NMe.NO$, $[162^\circ]$. Formed from di-methyl-amido-phenyl-ethane, HCl, and $NaNO_2$ (Heumann a. Wiernik, B. 20, 2423). Needles, insol. water, sl. sol. ether and gold alcohol. Zinc and HOAc reduce it to ethylphenyl-methyl-hydrazine, the acetyl derivative of which melts at 68° .

Di-methyl-amido-phenyl-ethane $[4:1]Et.C_6H_4.NMe_2$, $[89^\circ]$. Formed, together with hexa-methyl-tri-amido-tri-phenyl-methane, by heating glycol (1 mol.) with dimethylaniline (2 mols.) and $ZnCl_2$ at 100° – 120° (H. a. W.). Needles or prisms (from alcohol), v. sol. ether, warm alcohol, and benzene, insol. water. Its salts are deliquescent, and its platinumchloride is unstable. Oxidising agents colour it blue.

Methylo-iodide $Et.C_6H_4.NMe.I$. From *p*-amido-phenyl-ethane and MeI (Hofmann, B. 7, 527).

Tetra-methyl-di-amido-di-phenyl-ethane $C_{22}H_{24}N_4$, i.e. $NMe_2.C_6H_4.CH_2.C_6H_4.NMe_2$, $[50^\circ]$, (over 300°). Prepared by heating ethylene bromide with dimethylaniline at 100° (Schoop, B. 13, 2196). Slender needles; sq. ether, ligroin, hot wood spirit, and alcohol, insol. water. With $FeCl_3$ it gives a green colouration, and finally quinone. But it does not yield a dye on oxidation. — $B''H_2$. Sol. water and alcohol. — Oxalate $B''2H_2C_2O_4$. — Picrate $B''C_6H_4(NO_2)_3OH$: yellow pp., sol. hot alcohol.

Methylo-iodide $C_{22}H_{24}N_4MeI$. From di-amido-di-phenyl-ethane, MeI, and a little KOH at 150° – 180° (Heumann a. Wiernik, B. 20, 809).

Tetra-methyl-di-amido-tri-phenyl-ethane $C_{27}H_{30}N_4$, i.e. $(NMe_2.C_6H_4.NMe_2).CH_2.C_6H_5$. This is the chief product of the action of acetophenone on dimethylaniline in presence of $ZnCl_2$ (Doebner a. Petschoff, A. 242, 339). Yellow oil, v. sol. ether, benzene, petroleum-ether, and hot alcohol. It boils above 360° with partial decomposition. It is not volatile with steam.

Hexa-methyl-tri-amido-tri-phenyl-ethane $NMe_2.C_6H_4.CH_2.CH(C_6H_4.NMe_2)_2$, $[125^\circ]$. Formed by heating $CH_2Cl.CHCl_2$ with dimethylaniline and $ZnCl_2$ at 110° – 120° (Heumann a. Wiernik, B. 20, 2424). White needles, insol. water, v. sl. sol. cold, sl. sol. hot, alcohol, v. sol. ether. With PbO_2 and HOAc it gives a greenish-blue colour.

Octo-methyl-tetra-amido-tetra-phenyl-ethane $C_{32}H_{34}N_8$, i.e. $(NMe_2.C_6H_4)_2.CH_2.CH(C_6H_4.NMe_2)_2$, $[90^\circ]$, $[300^\circ]$. Formed by heating acetylene tetra-bromide with dimethylaniline at 100° (Schoop, B. 13, 2199). Prisms, sol. alcohol, ether, and benzene, insol. water. With $FeCl_3$ or CrO_3 it produces quinone. — $B''2H_2PtCl_6$: yellow amorphous pp. — Picrate $B''C_6H_4(NO_2)_3OH$: yellow plates, sol. hot water.

Deca-methyl-penta-amido-penta-phenyl-ethane $C_{37}H_{40}N_{10}$, $[184^\circ]$. Formed by heating a mixture of dimethylaniline (50 g.), chloral hydrate (20 g.), and $ZnCl_2$ (10 g.) at 100° ; the yield being 10 g. (O. Fischer, B. 11, 951; A. 206, 120; Boessneck, B. 18, 1516). Colourless needles (containing aq) (from alcohol), v. sol. chloroform. Sol. benzene, v. sl. sol. alcohol and ether. On oxidation it gives a greenish-blue dyestuff.

DI-METHYL- α -AMIDO- $\alpha\alpha$ -DI-PHENYL-ETHYL ALCOHOL $NMe_2.CHPh.CHPh.OH$, $[110^\circ]$. From $NH_2.CHPh.CHPh.OH$, MeI, and $EtOH$ (Goldschmidt a. Polonowska, B. 20, 494). White needles. — $B''H_2PtCl_6$ 3aq.

DI-METHYL-AMIDO-PHENYL ETHYL DITHIO-CARBONATE $EtO.CS.SC.C_6H_4.NMe_2$, $[54^\circ]$. Formed from di-methyl-*p*-phenylene-diamine by diazotising and heating the product with aqueous potassium xanthate at 70° (Leuckhart, J. pr. [2] 41, 206). Light-yellow crystals, insol. water, sol. ordinary menstrua. With alcoholic potash it gives $S(C_6H_4.NMe_2)_2$.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-FURFURYL-METHANE $C_{22}H_{24}O_2$, $[83^\circ]$. Prepared by the action of furfuraldehyde on dimethylaniline (O. Fischer, B. 11, 950).

DI-METHYL-AMIDO-PHENYL-GLYOXYLIC ACID $C_{15}H_{11}NO_5$, i.e. $NMe_2.C_6H_4.CO.CO_2H$, $[187^\circ]$. Obtained by saponifying its ethyl ether which is produced by adding $Cl.CO.CO_2Et$ to dimethylaniline at 100° (Michael a. Hanhardt, B. 10, 2081). Small plates or needles. Sol. water and alcohol. — NaA' (dried at 150°). Small needles. — BaA'_2 (dried at 150°). Plates.

Ethyl ether EtA' , $[95^\circ]$. Yellow plates (from alcohol). Cannot be distilled.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-HEPTANE $(NMe_2.C_6H_4)_2.CH_2.C_6H_5$, $[59-5^\circ]$, $[275^\circ]$ at 15 mm.). Formed from dimethylaniline, heptic aldehyde (ananthol) and $ZnCl_2$ (Krafft, B. 19, 2987). Crystalline solid, not readily oxidised. — $B''H_2PtCl_6$: yellow crystalline pp., v. sl. sol. water and ether-alcohol.

DI-METHYL-AMIDO-PHENYL-IMIDO-QUINOLINE TETRAHYDRIDE THIOSULPHONIC ACID

by oxidising a mixture of quinoline tetrahydride (1 mol.) with di-methyl-*p*-phenylene-diamino thio-sulphonic acid (1 mol.) by $\text{K}_2\text{Cr}_2\text{O}_7$ (Lellmann a. Boye, *B.* 23, 1374). Small lustrous green needles, sl. sol. water. Changes after some time to a brown powder. Zinc-dust and HCl reduce it, and the product yields a blue dye on oxidation.

DI-METHYL-AMIDO-PHENYL HEXYL KETONE $\text{C}_{11}\text{H}_{23}\text{NO}$ i.e. $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{C}_6\text{H}_{13}$. [49°]. (190° at 20 mm.). Formed, together with the leuco-base $\text{C}_{23}\text{H}_{29}\text{N}_2$, by adding heptyl chloride to a mixture of ZnCl_2 and dimethylaniline (Krafft, *B.* 19, 2987; Auger, *B.* [2] 47, 44). Colourless needles. Gives with conc. HNO_3 a nitro-compound $\text{C}_6\text{H}_4(\text{NO}_2) \cdot \text{CO} \cdot \text{C}_6\text{H}_5 (\text{NMe}_2)$ [65°].

Oxim $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{C}(\text{NOH}) \cdot \text{C}_6\text{H}_{13}$. [99°]. Colourless leaflets.

DI-METHYL-DI-AMIDO-DI-PHENYL-KETONE v. DI-METHYL-DI-AMIDO-BENZOPHENONE.

DI-METHYL-AMIDO-PHENYL MERCAPTAN $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{SH}$. [28°]. (260°). Obtained by reducing tetra-methyl-di-amido-di-phenyl sulphide with tin and HCl (Merz a. Weith, *B.* 19, 1575; Leuckart, *J. pr.* [2] 41, 207). Oil. Dissolves in NaOH aq. Re-oxidised by air to $(\text{NMe}_2 \cdot \text{C}_6\text{H}_5)_2\text{S}_2$ [118°].— $\text{Pb}(\text{SC}_6\text{H}_5)_2$: plates.

Di-methyl-di-amido-phenyl mercaptan $\text{C}_6\text{H}_5\text{N}_2\text{S}$ i.e. $\text{C}_6\text{H}_5(\text{NMe}_2)(\text{NH}_2)(\text{SH})$ [4:1:2]. Formed by reducing methylene red (Jacobsen, *B.* 21, 3104; Bernthsen, *A.* 251, 1). Gives a diazo-sulphide $\text{C}_6\text{H}_5(\text{NMe}_2) \begin{array}{c} \diagup \text{N} \\ \diagdown \text{N} \end{array} \text{N}$ [78°].

FeCl_3 gives a blue colouration. With AcCl in benzene it gives the hydrochloride of ethenyl-amido-dimethylamido-phenyl mercaptan $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{N} \\ \diagdown \text{S} \end{array} \text{CMe} = \text{Zn}(\text{C}_6\text{H}_5\text{N}_2\text{S})_2$.

DI-METHYL-AMIDO-DI-PHENYL-METHANE $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5$. This is perhaps the base, boiling at 335°, produced by heating di-methyl-aniline benzylo-chloride in a sealed tube at 230° (Michler, *B.* 10, 2079).

Di-methyl-di-amido-di-phenyl-methane $\text{NMe}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5 \cdot \text{NH}_2$. [93°]. Formed by boiling *p*-nitro-di-methyl-amido-di-phenyl-carbinol with zinc-dust and HCl (Albrecht, *B.* 21, 3296). Colourless needles, coloured bluish-violet by PbO_2 or by tetra-chloro-quinone.

Tetra-methyl-di-*p*-amido-di-phenyl-methane $\text{C}_6\text{H}_4\text{N}_2 \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_4(\text{NMe}_2)_2$. [91°].

Formation.—1. By heating methylene iodide, CHCl_3 or CCl_4 with dimethylaniline (Hanbhart, *B.* 12, 680; Doeberner, *B.* 12, 810; cf. Hanniman, *B.* 10, 1235).—2. By heating methylal $\text{CH}_2(\text{OMe})_2$ (1 mol.) with dimethylaniline (2 mols.) in presence of ZnCl_2 to 120° (O. Fischer, *B.* 22, 1689; *A.* 206, 117); or by acting on a mixture of methylal and dimethylaniline with conc. HCl aq. (Tröger, *J. pr.* [2] 36, 237).—3. One of the products of the action of acetophenone or of di-ethyl-ketone on dimethylaniline in presence of ZnCl_2 (Doeberner a. Petschhoff, *A.* 242, 888).—4. By heating dimethyl-

aniline with $\text{CCl}_4 \cdot \text{SO}_2\text{Cl}$ at 100° (Michler a. Moro, *B.* 12, 1170).—5. One of the products of the action of (α)-naphthylamine, sulphonio chloride on dimethylaniline (Michler a. Salathé, *B.* 12, 1789).—6. From C_6Cl_6 , dimethylaniline and ZnCl_2 (Heumann a. Wiernik, *B.* 20, 2426).—7. One of the products of the action of zinc and HCl on a mixture of dimethylaniline and CS_2 (Wiernik, *B.* 21, 3204; cf. Tröger, *J. pr.* [2] 36, 241).—8. By distilling tetra-methyl-di-amido-benzophenone (1 pt.) with zinc-dust (10 pts.) (Nathansohn a. Müller, *B.* 22, 1882).—9. A product of the action of Ac_2O on dimethylaniline (Reverdin a. De la Harpe, *B.* 22, 1006).—10. The chief product of the action of methyl hexyl ketone on dimethylaniline (Doeberner a. Petschhoff, *A.* 242, 812).—11. By distilling tetra-methyl-di-amido-thio-benzophenone with zinc-dust (Baither, *B.* 20, 1737).

Properties.—Four-sided tables or glistening leaflets (from alcohol). Insol. water, sl. sol. cold, m. sol. hot, alcohol, v. sol. benzene, ether, and CS_2 . Not volatile with steam. On oxidation with HOAc and MnO_2 it gives a fugitive blue colour. When boiled with MnO_2 and H_2SO_4 it yields quinone. Its alcoholic solution is turned blue by boiling with tetra-chloro-quinone. It may be oxidised to tetra-methyl-di-amido-benzophenone ($\text{N} \cdot \text{A} \cdot \text{M}$). Conc. HNO_3 in HOAc forms a tetra-nitro-derivative which decomposes at 218°. With tri-nitro-benzene it forms a compound $\text{C}_{11}\text{H}_{12}\text{N}_6\text{O}_6$ [114°], and with *m*-di-nitro-benzene a compound $(\text{C}_{11}\text{H}_{12}\text{N}_6\text{O}_6)_2$ [74°] (Van Romburgh, *R. T. C.* 7, 226).

Salts.— $\text{B}''\text{H}_2\text{I}_2$: sparingly soluble tables. $\text{B}''\text{H}_2\text{PtCl}_6$: yellow precipitate.—**Picrate.** $\text{B}''\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$. [178°].

Methylo-iodide $\text{B}''\text{MeI}_2$. [214°]. Yellow plates, v. sol. hot water and alcohol, insol. ether (D. a. P.).

Tetra-methyl-*exo-pp*-tri-amido-di-phenyl-methane $(\text{NMe}_2 \cdot \text{C}_6\text{H}_5)_3\text{CH} \cdot \text{NH}_2$. [136°]. Obtained by reducing the imide of tetra-methyl-di-amido-benzophenone (auramin-) with sodium-amalgam (Gräbe, *B.* 20, 3265). Colourless crystals; v. sl. sol. water, m. sol. alcohol. Gives an intense blue colouration with HOAc .

Methyl-*exo*-amido-tri-phenyl-methane $\text{C}_{10}\text{H}_{10}\text{N}$ i.e. $(\text{C}_6\text{H}_5)_3\text{C} \cdot \text{NHMe}$. [73°]. Obtained by passing methylamine into a hot solution of Ph_3CBr in benzene (Hemilian a. Silberstein, *B.* 17, 745). Prisms (from ligroin). Insol. water, v. sol. alcohol.— $\text{B}''\text{H}_2\text{PtCl}_6$ 6aq.— $\text{B}''\text{I}_2$. Ppd. as lustrous blue-black needles by adding iodine to its solution in CS_2 .

Di-methyl-*exo*-amido-tri-phenyl-methane $\text{C}_{21}\text{H}_{21}\text{N}$ i.e. $(\text{C}_6\text{H}_5)_3\text{C} \cdot \text{NMe}_2$. [07°]. From *exo*-bromo-tri-phenyl-methane and NMe_2 in benzene (H. a. S.). Insol. water, v. sol. alcohol.— $\text{B}''\text{H}_2\text{PtCl}_6$.

Di-methyl-amido-tri-phenyl-methane $\text{C}_{21}\text{H}_{21}\text{N}$ i.e. $(\text{C}_6\text{H}_5)_3\text{CH} \cdot \text{C}_6\text{H}_5 \cdot \text{NMe}_2$. [132°].

Formation.—1. By heating di-phenyl-carbinol with di-methyl-aniline and P_2O_5 at 150° (O. Fischer, *B.* 11, 951; 12, 1690; *A.* 206, 114).—2. By heating benzophenone chloride Ph_2CCl_2 with dimethylaniline and ZnCl_2 (F.; cf. Pauly, *A.* 187, 209).

Preparation.—Benzophenone (10 g.), di-methylaniline (18 g.) and zinc chloride (10 g.)

are heated in sealed tubes for ten hours to 190°. After driving over excess of dimethylaniline and benzophenone the residue is extracted with ether, and after distilling this off the base is recrystallised from alcohol (Doebner a. Petschow, *A.* 242, 342).

Properties.—Colourless needles; sl. sol. alcohol, v. sol. ether and benzene. Does not give a colouring matter on oxidation. Is a weak base, and does not combine with HOAc.

Salts.— B^+HCl^- . $B^+H_2PtCl_6^-$: needles; sl. sol. hot water.

Methylo-iodide $C_{21}H_{21}NMeI$. [186°]. Large white plates.

Tetra-methyl-di-amido-tri-phenyl-methane $C_{22}H_{22}N_2$, i.e. $(NMe_2.C_6H_4)_2CH.C_6H_5$. *Leuco-base of malachite green*. [102°] and [94°].

Formation.—1. By heating a mixture of benzoic aldehyde (10 pts.) and dimethylaniline (23 pts.) with $ZnCl_2$. The yield is 90 p.c. (O. Fischer, *B.* 10, 799, 1624; 11, 950, 2274; 12, 1685; *A.* 206, 122).—2. From benzylidene chloride, dimethylaniline, and $ZnCl_2$.—3. By heating di-amido-tri-phenyl-methane with MeI and MeOH at 130° (F.).—4. By heating its carboxylic acid (di-methyl-aniline phthalin) $(NMe_2.C_6H_4)_2CH.C_6H_4.CO_2H$ with barium hydroxide.—5. From tetra-methyl-di-amido-tri-phenyl-carbinol (malachite green) by reduction with zinc-dust and HCl (Doebner, *B.* 11, 1230; *A.* 217, 256).—6. A by-product in the action of phthalyl chloride and in that of benzoyl chloride on dimethylaniline.—7. By heating phenylglyoxylic acid with dimethylaniline and $ZnCl_2$ (Peter, *B.* 13, 539).—8. A by-product in the action of $ZnCl_2$ on a mixture of dimethylaniline and acetophenone (Doebner a. Petschhoff, *A.* 242, 333).

Preparation.—A mixture of benzoic aldehyde (40 g.), dimethylaniline (100 g.), and 93 p.c. alcohol (40 g.) is heated on a water-bath, and $POCl_3$ (65 g.) added slowly. The product is extracted with water, the filtrate ppd. by soda and the pp. recrystallised from alcohol (Nencki, *M.* 9, 1148).

Properties.—Crystallises from benzene in [apparently triclinic] needles, melting at 102°, and from alcohol in triclinic leaflets, melting at 94° (E. a. O. Fischer, *B.* 12, 796). Insol. water, v. sol. ether and benzene, sl. sol. petroleum. In small quantities it can be distilled. Its salts are oxidised by MnO_2 or PbO_2 to malachite green. Nitric acid forms a hexa-nitro-derivative [200°]. When distilled with zinc-dust it is reduced to aniline, dimethylaniline, and *p*-amido-di-phenyl-methane (Manns, *O. C.* 1888, 1363).

Salts.— $B^+H_2Cl_2^-$: colourless hygroscopic needles; v. sol. water. Gives off HCl at 100°, becoming B^+HCl^- . $B^+H_2PtCl_6^-$: white pp., soon becoming yellowish-green.—The aurochloride is a golden-yellow flocculent pp.—Picrate $B^+2C_6H_5(NO_2)_3OH^-$. [220°]. Aggregations of needles; m. sol. water.

Di-methylo-di-iodide $B^+Me_2I_2^-$. [218°–222°] (F.); [231°] (Doebner, *B.* 13, 2228). Plates, tables, or leaflets; v. sol. water. Decomposed on fusion into MeI and the base.

Tetra-methyl-ppm-tri-amido-tri-phenyl-methane $([4:1]NMe_2.C_6H_4)_2CH.C_6H_5.NH_2$ [1.2]. [185°]. *o*-Amido-leuco-malachite green. Formed by reducing, by means of zinc-dust and HCl, the

product of the condensation of *o*-nitro-benzole aldehyde with dimethylaniline (Fischer a. Schmidt, *B.* 15, 688; 17, 1891). Colourless crystals (containing C_6H_5). Gives a reddish-brown dye-stuff on oxidation.

Acetyl derivative $C_{21}H_{21}(NMe_2)_2(NHAc)$. [186°]. Glistening crystals. Gives on oxidation $(NMe_2.C_6H_4)_2C(OH).C_6H_5.NHAc$.

Tetra-methyl-tri-amido-tri-phenyl-methane $C_{22}H_{22}N_3$, i.e. $(NMe_2.C_6H_4)_2CH.C_6H_5.NH_2$. [65°]. Prepared by dissolving tetra-methyl-di-*pp*-amido-di-phenyl-carbinol (20 pts.) in $HClAq$ (12 pts. of S.G. 1.18) and water (100 pts.), heating to 100°, and adding aniline hydrochloride (10 pts.) (Nathansohn a. Müller, *B.* 22, 1886). Small needles (from warm alcohol); v. sol. alcohol, ether, and benzene; insol. water. According to analogy it should be identical with the preceding body. With MeI it gives $CH(C_6H_5.NMe_2)_3$, [172°].

Salts.— $B^+H_2Cl_2^-$: yellowish-green crystalline pp., got by adding HCl to an ethereal solution of the base. V. sol. hot alcohol, sl. sol. ether, insol. benzene.— $B^+H_2PtCl_6^-$: light-yellow flocculent pp.; v. sl. sol. water and alcohol.—Picrate $B^+C_6H_5(NO_2)_3OH^-$: light-green flocculent pp.; v. sol. hot alcohol, insol. benzene and ether.

Benzoyl derivative $(NMe_2.C_6H_4)_2CH.C_6H_5.NHBz$. [128°]. Small, slender blue plates (from warm alcohol); v. sol. hot alcohol and benzene, sl. sol. ether, insol. water.

Tetra-methyl-ppm-tri-amido-tri-phenyl-methane $([4:1]NMe_2.C_6H_4)_2CH.C_6H_5.NH_2$ [1.3]. [130°]. Prepared by reducing *m*-nitro-tetra-methyl-di-amido-tri-phenyl-carbinol (E. a. O. Fischer, *B.* 12, 803). Colourless prisms or needles. Gives a green dye on oxidation.

Tetra-methyl-tri-p-amido-tri-phenyl-methane $C_{22}H_{22}N_3$, i.e. $([4:1]NMe_2.C_6H_4)_2CH.C_6H_5.NH_2$ [1.4]. [152°]. Prepared by reducing the hydrochloride of *p*-nitro-tetra-methyl-di-*p*-amido-tri-phenyl-methane with zinc-dust (Fischer, *B.* 14, 2527). Colourless plates, sl. sol. alcohol. Gives on oxidation tetra-methyl-pararosanine, a reddish-violet dye.

Acetyl derivative [108°]. Needles. Yields on oxidation the corresponding carbinol, a splendid green dye (Fischer a. German, *B.* 16, 708).

Penta-methyl-tri-p-amido-tri-phenyl-methane $C_{23}H_{23}N_3$, i.e. $(NMe_2.C_6H_4)_2CH.C_6H_5.NMeH$. [116°]. Obtained by heating penta-methyl-pararosanine with alcoholic ammonium sulphide at 100° (Hofmann, *B.* 6, 360; E. a. O. Fischer, *B.* 12, 799; Fischer a. Körner, *B.* 16, 2906). Large colourless needles (from alcohol). Sl. sol. hot water, v. sol. alcohol and ether.— $B^+3H_2PtCl_6^-$.

Acetyl derivative [143°].
Hexa-methyl-tri-amido-tri-phenyl-methane $C_{24}H_{24}N_3$, i.e. $HC(C_6H_5.NMe_2)_3$. *Hexa-methyl-paraleucanine*. [173°].

Formation.—1. By treating chloral with dimethylaniline and $ZnCl_2$ (E. a. O. Fischer, *B.* 11, 2097). The base so prepared melted, however, at 250°.—2. From orthoformic ether (1 pt.) and dimethylaniline (3½ pts.) at 100° (Fischer a. Knorr, *B.* 17, 98).—3. By condensation of *p*-dimethyl-amido-benzaldehyde with dimethylaniline in presence of dry HCl gas or $ZnCl_2$ (Boess-

neck, *B.* 19, 866).—4. From glycol, dimethyl-aniline, and ZnCl_2 at $100^\circ\text{--}120^\circ$ (Heumann a. Wiernik, *B.* 20, 2421). Needles or prisms. When oxidised with MnO_2 and H_2SO_4 it gives formic aldehyde and methyl violet (Fischer).

Tri-methylo-tri-iodide $\text{C}_{18}\text{H}_{15}\text{N}_3\text{I}_3$ i.e. $\text{OH}(\text{C}_6\text{H}_4\text{NMe}_2)_3$. [185°]. From tetra- and hexa-methyl-tri-*p*-amido-tri-phenyl-methane, MeI , and MeOH at 100° (Hofmann a. Girard, *B.* 2, 448; Fischer, *B.* 12, 2344). Yellow needles (containing aq), decomposes and becomes dark blue on fusion. Gives $(\text{C}_6\text{H}_4\text{N}_2\text{Cl}_2)_3\text{PtCl}_2$ 2aq.

Hexa-methyl-*opp* (?) -tri-amido-tri-phenyl-methane. Tri-methylo-tri-iodide $\text{OH}(\text{C}_6\text{H}_4\text{NMe}_2)_3$. [172°]. Obtained by heating the corresponding tetra-methyl-tri-amido-tri-phenyl-methane with MeI (Nathansohn a. Müller, *B.* 22, 1887). Small brown needles (from warm alcohol); v. sol. alcohol and hot water, almost insol. ether and benzene.

Hexa-methyl-*mpp* -tri-amido-tri-phenyl-methane. Tri-methylo-tri-iodide $[3:1]\text{NMe}_2\text{I.C}_6\text{H}_4\text{OH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$. [1:4]]. Formed by heating the base $\text{C}_6\text{H}_4\text{N}_2$ or the corresponding $\text{CH}(\text{C}_6\text{H}_4\text{NH}_2)_3$ with MeI and MeOH at 120° (Fischer, *B.* 12, 802; 13, 673). Crystallises with difficulty, and is v. e. sol. water. Gives rise to $8\text{PtCl}_2\text{O}(\text{C}_6\text{H}_4\text{NMe}_2\text{Cl})_3$.

References.—CHLORO-, CHLORO-NITRO-, and NITRO-, METHYL-AMIDO-PHENYL-METHANES.

TETRA-METHYL-DI-AMIDO-TRI-PHENYL-METHANE CARBOXYLIC ACID $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_5$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_3\text{CH.C}_6\text{H}_4\text{CO}_2\text{H}$. *Di-methyl-aniline phthalin*. [200°]. Obtained by treating dimethyl-amido-phthalide with zinc-dust and HCl (Fischer, *A.* 206, 101). Formed also by treating *p*-aldehyde-benzoic acid with dimethylaniline and ZnCl_2 (Löw, *A.* 231, 367). Plates (from alcohol), v. sol. ether, sl. sol. ligroin, m. sol. alcohol. Conc. H_2SO_4 forms a bluish-violet solution. Its zinc salt melts at 147° (L.). —Platinochloride $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_5\text{H}_2\text{PtCl}_6$. —Picrate: $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_5\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$.

TETRA-METHYL-DI-AMIDO-TRI-PHENYL-METHANE CARBOXYLIC ALDEHYDE $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_4$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_3\text{CH.C}_6\text{H}_4\text{CHO}$. From terephthalic aldehyde, dimethylaniline, alcohol, and ZnCl_2 (Löw, *A.* 231, 381). Needles (from chloroform). Sl. sol. alcohol, m. sol. benzene, v. sol. chloroform. Its phenylhydrazide melts at 225° — $\text{B}''\text{H}_2\text{PtCl}_6$.

DI-METHYL-AMIDO-PHENYL (a) -NAPHTHYL SULPHONE $\text{C}_{18}\text{H}_{15}\text{N}_2\text{SO}_2$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{SO}_2\text{C}_{10}\text{H}_7$. Formed, together with tetra-methyl-di-amido-di-phenyl-methane, by heating dimethylaniline (2 mols.) with the chloride of naphthalene (a)-sulphonic acid (Michler a. Salathé, *B.* 12, 1789). Crystals, v. sol. alcohol and ether. Conc. HClAq at 180° splits it up into naphthalene, H_2SO_4 , aniline, and MeCl . Zinc and H_2SO_4 give dimethylaniline and naphthyl mercaptan. Fuming HNO_3 gives tetra-nitro-methyl-aniline and nitro-naphthalene sulphonic acid.

Di-methyl-amido-phenyl (b)-naphthyl sulphone. Resembles the preceding body in its mode of preparation, properties, and decompositions (*M. a. S.*).

DI-METHYL-*p*-AMIDO-PHENYL-OXAMIC ACID $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_4$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{NH.CO.CO}_2\text{H}$. [192°]. The ethyl ether is formed by boiling di-

methyl-*p*-phenylene-diamine with oxalic ether and separated by solution in alcohol from the accompanying tetra-methyl-di-amido-di-phenyl oxamide (Sendtner, *B.* 12, 530). The ether is then saponified by alcoholic KOH . Needles (from water) or plates (from alcohol).

Ethyl ether EtA'. [117°]. Yellow plates or needles, v. sol. warm alcohol.

DI-METHYL-AMIDO-PHENYL-OXAMIDE $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_2$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{NH.CO.CO.NH}_2$. [259°]. Formed by treating di-methyl-amido-phenyl-oxamic ether with alcoholic NH_3 (Sendtner, *B.* 12, 532). Nodules (from alcohol).— $\text{B}'_2\text{H}_2\text{SO}_4$: crystals.

Tetra-methyl-di-amido-di-phenyl-oxamide $\text{NMe}_2\text{C}_6\text{H}_4\text{NH.CO.CO.NH.C}_6\text{H}_4\text{NMe}_2$. Formed as described under di-methyl-amido-phenyl-oxamic acid (Sendtner). Small yellow needles, insol. water, sl. sol. boiling alcohol. Does not melt at 270° . Diaacid base, forming salts soluble in water.

TETRA-METHYL-DI-AMIDO-DI-PHENYL OXIDE $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{O}$. [119°]. Formed by boiling the corresponding sulphide ('thiodimethylaniline') with an ammoniacal alcoholic solution of AgNO_3 (Holzmann, *B.* 21, 2056). Stellate groups of colourless needles, insol. water, sl. sol. cold alcohol, ether, and benzene. Readily soluble in acids. Conc. HClAq at 200° gives MeCl and aniline.— $\text{B}''\text{H}_2\text{PtCl}_6$: minute bright yellow plates, sl. sol. hot alcohol.—Picrate. $\text{B}'_2\text{C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$. [150°]. Small yellow needles, sl. sol. cold alcohol and benzene.

Tetra-methyl-di-amido-di-phenyl-di-oxide $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{O}_2$. *Di-ox-di-methyl-aniline*. [91°]. Obtained by adding (4 mols. of) silver nitrate to an alcoholic solution of tetra-methyl-di-amido-di-phenyl-di-sulphide $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{S}_2$ (1 mol.) treated with conc. NH_3 . It is also formed by the action of FeCl_3 upon the conc. HCl solution of the same base. Thin silky needles, or plates. V. e. sol. alcohol, ether, and benzene, sol. hot water. It dissolves in acids, but its salts are not crystalline (Merz a. Weith, *B.* 19, 1573).

TETRA-METHYL-DI-AMIDO-DI-PHENYL OXINDOLE $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}$ i.e. $\text{C}_6\text{H}_5\text{—C}(\text{O}_6\text{H}_4\text{NMe}_2)_2$.

Di-methyl-aniline NH—CO isatin. [234°]. Formed by heating isatin with dimethylaniline and ZnCl_2 (Baeyer a. Lazarus, *B.* 18, 2642). Glistening colourless prisms. Sl. sol. ether, alcohol, and ligroin, insol. water. Dissolves in acids. On oxidation it gives a splendid bluish-green dye-stuff.

DI-METHYL-AMIDO-TRI-PHENYL-PHOSPHINE $\text{C}_{18}\text{H}_{15}\text{NP}$ i.e. $\text{NMe}_2\text{C}_6\text{H}_4\text{P}(\text{C}_6\text{H}_5)_3$. [152°]. Formed by the action of sodium on a mixture of chloro-benzene and $\text{NMe}_2\text{C}_6\text{H}_4\text{PCl}_2$ (Schenck a. Michaelis, *B.* 21, 1502). Colourless crystals, v. e. sol. benzene, sl. sol. alcohol and ether. Weak base, being almost entirely ppd. by water from its solution in HClAq .

Hexa-methyl-tri-amido-tri-phenyl-phosphine $(\text{NMe}_2\text{C}_6\text{H}_4)_3\text{P}$. [273°]. Formed by heating dimethylaniline with PCl_3 in a sealed tube (Hannemann, *B.* 9, 845). Formed also as a by-product, in the action of PCl_3 on dimethylaniline in presence of AlCl_3 (S. a. M.). Colourless needles,

which turn blue on exposure to air. V. e. sol. chloroform, v. sol. dilute HClAq, m. sol. hot alcohol.

DI-METHYL-AMIDO-PHENYL PHOSPHINOUS ACID v. DI-METHYL-AMIDO-BENZENE PHOSPHINOIC ACID.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-PHTHALIDE $C_{24}H_{22}N_2O_2$ i. e.

$(NMe_2.C_6H_4)_2C \begin{smallmatrix} O \\ \diagup \diagdown \end{smallmatrix} CO$. *Dimethylaniline-phthalein*. [1917]. Prepared by heating dimethylaniline with $ZnCl_2$ and phthalyl chloride or phthalic anhydride (O. Fischer, B. 9, 1753; 10, 952; 12, 1691; A. 206, 92). Colourless pointed crystals, insol. water, v. sol. benzene, v. sl. sol. ligroin. Reduced by zinc-dust and HOAc to tetra-methyl-di-amido-tri-phenyl-methane carboxylic acid (dimethylaniline-phthalin). Potash-fusion gives dimethylaniline, HOBz, and phthalic acid. HNO_3 gives a hexa-nitro-derivative which decomposes at 230° .

Salts.— $B'HCl$: small needles, m. sol. water. — $B''H_2Cl_2$: hygroscopic crystalline mass, got by passing HCl into the ethereal solution. Gives off HCl (1 mol.) at 100° . — $B''H_2PtCl_6$: crystalline pp. — $B''H_2PtCl_6$ aq: prisms. — Picrate $B''2C_6H_3(NO_2)_3OH$.

Methylo-iodide $B'MeI_2$. [c. 185°].

Phthal-green $C_{22}H_{18}N_2O_2$. This substance, isomeric with the preceding, is also formed in the action of phthalyl chloride on di-methylaniline in presence of $ZnCl_2$ (Fischer). Its hydrochloride, $B'HCl$, forms greenish-yellow needles, m. sol. water. Its zinc double salt crystallises in brass-yellow needles which form a green solution in water. Zinc and I_2Cl reduce it to a leuco-base $C_{22}H_{21}N_2O$ which crystallises in small prisms [230°], and is easily re-oxidised to phthal-green.

TETRA-METHYL-DI-AMIDO-PHENYL-DI-PHENYLENE-OXIDE-CARBINYL CHLORIDE

$C_6H_5.C \begin{smallmatrix} C_6H_4NMe_2 \\ \diagup \diagdown \\ C_6H_4NMe_2 \end{smallmatrix} Cl$. *Tetra-methyl-rosamine*.

Formed from benzotrichloride and dimethyl-*m*-aridophenol at 50° – 60° (Heumann a. Rey, B. 22, 3002). Dark-red flocculent pp., strongly fluorescent in acid or neutral solution. H_2SO_4 dissolves it giving an orange-yellow colour, becoming dark-red on addition of water. Silk and wool are dyed in feebly acid bath rose to bluish-red.

Salts.— $B'HCl$: dark-red needles with steel-blue reflex, v. sol. water and EtOH formingsolutions with a splendid blue-red colour, and yellow fluorescence. — $(C_{22}H_{18}N_2OCl)_2PtCl_6$: dark-red pp.

DI-METHYL-AMIDO-PHENYL-PROPANE $C_{11}H_{11}N$ i. e. $NMe_2.C_6H_4.CH_2.CH_2.CH_3$. *Dimethyl-amido-propyl-benzene*. (230°). From *p*-bromo-di-methyl-aniline, propyl bromide, and sodium (Claus a. Howitz, B. 17, 1327). Oil.

Methylo-iodide $NMe_2.I.C_6H_4.Pr$. [168°]. **Tetra-methyl-di-amido-di-phenyl-propane** $(NMe_2.C_6H_4)_2CMe_2$. [83°]. From acetone (1 mol.), dimethylaniline (2 mols.), and $ZnCl_2$ (Döbner, B. 12, 813). Long needles.

DI-METHYL-AMIDO-PHENYL-QUINON-

IMIDE $C_{11}H_9N_2O$ i. e. $C_6H_5 \begin{smallmatrix} O \\ \diagup \diagdown \\ N.C_6H_4NMe_2 \end{smallmatrix}$

Phenol-blue. Formed by adding quinone chlor-

imide to a solution of di-methyl-aniline in concentrated aqueous oxalic acid (Fogh, B. 21, 889). Formed also by the action of NaOH on di-methyl-phenylene green (Möhlau, B. 18, 2914). Black crystals (containing $\frac{1}{2}$ aq.) Yields, when treated with hot dilute HClAq, quinone and di-methyl-phenylene-*p*-diamine. May be reduced to a leuco-base.

Sulphonic acid

$SO_3.H.C_6H_5 \begin{smallmatrix} O \\ \diagup \diagdown \\ M.C_6H_4NMe_2 \end{smallmatrix}$. Formed by passing

chlorine into amido-phenol sulphonic acid suspended in water, and then adding di-methylaniline (F). Slender needles, v. sl. sol. hot alcohol, insol. cold water and ether. Its alkaline solutions are blue. Conc. H_2SO_4 forms a cherry-red solution.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-SULPHIDE $(NMe_2.C_6H_4)_2S$. *Thiodimethylaniline*. [126°]. Formed by heating dimethylaniline with persulphocyanic acid or SCl_2 (Tur sin, B. 17, 584; Holzmann, B. 20, 1640; 21 2050; Michaelis a. Godchaux, B. 23, 554). Light-yellow needles, sl. sol. alcohol and benzene.

Reactions.—1. Silver nitrate converts it into $(NMe_2.C_6H_4)_2O$.—2. On heating with reduced copper (10 pts.) at 300° it yields NPhMe.

Salts.— $B''H_2Cl_2$. [176°]. White mass becoming coloured in the air, extremely sol. water. — $B''H_2PtCl_6$ 2aq. — $B''H_2FeCy_6$ 6aq: white powder, m. sol. water. — $B''C_6H_3(NO_2)_3OH$. [142°]. Yellow needles (from hot alcohol). — $B''2C_6H_3(NO_2)_3OH$. Amorphous. [146°]. — $B'HNCS$: [168°]; pearly plates.

Tetra-methyl-di-amido-di-phenyl-di-sulphide $(NMe_2.C_6H_4)_2S_2$. *Di-sulphido- or di-thio-dimethylaniline*. [118°]. Formed by adding S_2Cl_2 , diluted with petroleum-ether, to a dilute solution of dimethylaniline in the same solvent (Merz a. Weith, B. 19, 1570). Formed also by heating di-methyl-*p*-amido-phenyl ethyl di-thiocarbonate with an alcoholic solution of aniline at 200° (Leuckart, J. pr. [2] 41, 208). Small yellow needles, e. sol. CS_2 , more sparingly in hot benzene, alcohol, and petroleum-ether, nearly insol. water. Copper-powder removes the sulphur at c. 230° forming dimethylaniline and other products. By the action of $FeCl_3$, or of alcoholic NH_3 and silver nitrate, it is converted into tetra-methyl-di-amido-di-phenyl-di-oxide $(NMe_2.C_6H_4)_2O_2$. By tin and HCl, or by sodium-amalgam, it is reduced to di-methyl-amido-phenyl-mercaptan, which is readily re-oxidised to the di-sulphide. Its salts are gummy and amorphous, they are decomposed by water.

Tetra-methyl-tetra-amido-di-phenyl-disulphide $(NMe_2.C_6H_4(NH_2))_2S_2$. Formed by atmospheric oxidation from di-methyl-di-amido-phenyl mercaptan $NMe_2.C_6H_4(NH_2)SH$ (Bernthsen, A. 251, 1). Thick oil, sol. ether, alcohol, and benzene. Dissolves in acids, but reppd. by alkalis. In benzene solution it combines with sulphur forming a persulphide [97°], apparently $C_{22}H_{18}N_4S_3$.

DI-METHYL-AMIDO-DI-PHENYL SULPHONE $C_{22}H_{18}SO_2.C_6H_4.NMe_2$. [78°] (R.); [82°] (M. a. M.). Formed by heating dimethylaniline with benzene sulphonic chloride (Miehler, B. 10, 1742; Van Romburgh, R. T. C. 2, 805; Miehler a. Meyer, B. 12, 1791; Hassencamp, B. 12,

1275). Needles (from alcohol), insol. water, v. e. sol. alcohol, ether, and benzene. HClAq at 180° splits it up into MeCl, aniline, and benzene. Zinc and H₂SO₄ reduce it to phenyl mercaptan and dimethylaniline. HNO₃ gives yellow crystals of tetra-nitro-methyl-aniline [127°].

METHYL-AMIDO-PHENYL-THIAZOLE

$\text{C}_{10}\text{H}_9\text{N}_2\text{S}$ i.e. $\begin{array}{c} \text{S}-\text{C}(\text{NHMe}) \\ | \\ \text{CH}_2\text{C}_6\text{H}_4 \end{array} \text{N}$. [138°]. From

ω -bromo-acetophenone and methyl-thio-urea (Traumann, A. 249, 46). Yellow plates (from ether), insol. water, m. sol. alcohol. With HClAq at 220° it yields methylamine.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-THIENYL-METHANE

$\text{C}_{22}\text{H}_{21}\text{N}_4\text{S}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CH}_2\text{C}_6\text{H}_3\text{S}$. *Thiophene leuco-malachite green*. [93°]. Formed by heating thiophenic aldehyde with dimethylaniline, ZnCl₂, and a little alcohol (Peter, B. 18, 538; Levi, B. 20, 514). Formed also by heating dimethyl-aniline with thienyl-glyoxylic acid $\text{C}_6\text{H}_3\text{S.CO.CO}_2\text{H}$ and ZnCl₂ (P.). Needles, insol. water, v. sol. alcohol and ether. The alcoholic solution turns green in the air. MnO₂ and dilute H₂SO₄ oxidise it to the carbinol $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{C}(\text{OH})\text{C}_6\text{H}_3\text{S}$, which is a dark-brown oil, sol. alcohol and ether, and forming salts which dye a splendid yellowish-green (*Thiophene green*).—Platinochloride $\text{C}_{22}\text{H}_{21}\text{N}_4\text{S}_2\text{H}_2\text{PtCl}_6$.—Picrate $\text{C}_{22}\text{H}_{21}\text{N}_4\text{S}_2\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{OH})$. [c. 208°]. Yellowish-green needles, sl. sol. cold water, v. sol. alcohol.

Di-methylo-di-iodide

$\text{C}_8\text{H}_8\text{S}_2\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$. [212°]. White plates.

TETRA-METHYL-DI-AMIDO-DI-PHENYL-THIOKETONE

or TETRA-METHYL-DI-AMIDO-THIO-BENZOPHENONE.

DI-METHYL-DI-AMIDO-PHENYL THIO-

SULPHURIC ACID

$\text{NMe}_2\text{C}_6\text{H}_3(\text{NH}_2)_2\text{S.SO}_3\text{H}$. [193°–204°]. Obtained by adding an alkali to a 1/10 p.c. solution of methylene red until the colour is destroyed, then acidulating with HOAc and exposing to the air. Formed also by the action of a strong solution of SO₂ on di-methyl-di-amido-phenyl mercaptan (Bernthsen, A. 251, 1). Crystals, sl. sol. water and alcohol. Its dilute aqueous solution gives a purple colour with traces of iodine or of FeCl₃. The hydrochloride crystallises in prisms.

Reactions.—1. A mixture of di-methyl-di-amido-phenyl thio-sulphuric acid with *dimethyl-aniline* when oxidised by K₂Cr₂O₇ and HOAc

forms the indamine $\text{C}_8\text{H}_8\text{N}_2\text{S} \begin{array}{c} \text{N.C}_6\text{H}_4(\text{NMe}_2) \\ | \\ \text{NMe}_2 \end{array} \text{O.SO}_2$, an

emerald-green powder (containing 3 aq), and yields $\text{NMe}_2\text{C}_6\text{H}_3\text{NH.C}_6\text{H}_3(\text{NMe}_2)_2\text{S.SO}_3\text{H}$ on reduction, a body which is v. sol. hot alcohol and acids.—2. A mixture of the thio-sulphuric acid with *aniline hydrochloride* gives on oxidation

$\text{C}_{11}\text{H}_{11}\text{N}_3\text{S}_2\text{O}_3$ i.e. $\text{C}_6\text{H}_5 \begin{array}{c} \text{N.C}_6\text{H}_4(\text{NMe}_2) \\ | \\ \text{NH}_2 \end{array} \text{O.SO}_2$ (?) an

insoluble green compound decomposed by water. Prolonged boiling with dilute FeCl₃ gives

$\text{C}_6\text{H}_5 \begin{array}{c} \text{N}(\text{NMe}_2) \\ | \\ \text{NH} \end{array} \text{S}$, a blue powder with bronze

lustre.—3. A mixture of di-methyl-di-amido-phenyl thio-sulphuric acid with α -toluidine yields

on oxidation the homologous $\text{C}_{11}\text{H}_9\text{N}_3\text{S}_2\text{O}_3$ as a bluish-grey powder.

Tetra-methyl-di-amido-phenyl thio-sulphuric acid $\text{C}_8\text{H}_8(\text{NMe}_2)_2\text{S.SO}_3\text{H}$. [175°–182°]. Obtained by dissolving tetra-methyl *p*-phenylene diamine (2.7 g.) in HCl (1.56 c.c. of 33 p.c.) and adding aluminium sulphate (10 g.), and sodium thiosulphate (6.6 g.) dissolved in water (36 c.c.). A cold solution of K₂Cr₂O₇ (25 c.c. of a 6.67 p.c. solution) is then added, and the resulting liquid left to stand. The precipitate which then separates is recrystallised from alcohol (Bernthsen, A. 251, 60). Plates, sol. hot water and acids. Zinc and HCl reduce it to the mercaptan $\text{C}_8\text{H}_8(\text{NMe}_2)_2\text{SH}$.

TETRA-METHYL-DI-*p*-AMIDO-DI-PHENYL

THIO-UREA

$\text{C}_{16}\text{H}_{22}\text{N}_4\text{S}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{NH}_2\text{S}$. [186°]. Formed by boiling di-methyl-*p*-phenylene-diamine with alcoholic CS₂ (Baur, B. 12, 533). White needles, insol. water and cold alcohol.—B'H₂Cl₂: crystalline powder.

Acetyl derivative [71°]. White plates.

TETRA-METHYL-DI-AMIDO-DI- ω -PHE-

NYL-TOLUIC ALDEHYDE

$\text{C}_{22}\text{H}_{22}\text{N}_4\text{S}$ i.e. $(\text{NMe}_2\text{C}_6\text{H}_4)_2\text{CH}_2\text{C}_6\text{H}_3\text{CHO}$. *Aldehyde of the leuco-base of malachite green*. [143°]. Obtained by boiling an alcoholic solution of terephthalic aldehyde $\text{C}_6\text{H}_4(\text{CHO})_2$ with di-methyl-aniline and ZnCl₂ (W. Löw, A. 231, 381). Prismatic needles (from chloroform). Forms a crystalline compound with NaHSO₄. Its phenyl hydrazide melts at 225°.—B'H₂IPtCl₆.

TRI-METHYL-TRI-AMIDO-DI-PHENYL-

TOLYL-CARBINOL

$\text{C}_{24}\text{H}_{24}\text{N}_6\text{O}$. Formed by heating rosaniline chloride (1 pt.) with MeI (2 pts.), MeOH (8 pts.), and KOH (1 pt.) (Hofmann). Formed also by allowing an alcoholic solution containing rosaniline and 'iodine green' to stand in the cold (Girard a. Willm, B. [2] 25, 200).

The salt $\text{NHMe.C}_6\text{H}_3\text{Me.C} \begin{array}{c} \text{C}_6\text{H}_4\text{NHMe} \\ | \\ \text{C}_6\text{H}_4\text{NHMe} \end{array} \text{Cl}$ is one

of the substances known as Hofmann's violet (Hofmann, C. R. 54, 428; 56, 945, 1033; 57, 1131). Its absorption-spectrum has been studied by Hartley (C. J. 51, 172).

Penta-methyl-tri-amido-di-phenyl-tolyl-carbinol

$\text{NMe}_2\text{C}_6\text{H}_4\text{Me.C}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)(\text{C}_6\text{H}_4\text{NHMe})$.

The chloride $\text{NMe}_2\text{C}_6\text{H}_4\text{Me.C} \begin{array}{c} \text{C}_6\text{H}_4\text{NMe}_2 \\ | \\ \text{C}_6\text{H}_4\text{NHMe} \end{array} \text{Cl}$

is probably the chief constituent of Hofmann's violet obtained by heating rosaniline with MeCl. It has a green lustre and forms a violet solution in water. The solution is decolourised by zinc dust. HCl turns the solution first green, then yellow. NaOH gives a brownish-red pp. Conc. H₂SO₄ gives a brownish-yellow solution changed, on dilution, through green to blue. It dyes wool, silk, and mordanted cotton violet.

Hexa-methyl-tri-amido-di-phenyl-tolyl-

carbinol $\text{NMe}_2\text{C}_6\text{H}_4\text{Me.C}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$. The zinc double salt of the methylo-chloride of this body $\text{C}_{28}\text{H}_{28}\text{N}_6\text{O}_2\text{Zn}$ or

$\text{NMe}_2\text{C}_6\text{H}_4\text{Me.C} \begin{array}{c} \text{C}_6\text{H}_4\text{NMe}_2 \\ | \\ \text{C}_6\text{H}_4\text{NMe}_2 \end{array} \text{ZnCl}_2$ appears to

constitute the dye known as 'iodine green,' which is obtained by heating rosaniline with MeCl, or by the action of MeCl on Hofmann's violet. The

corresponding iodide $C_{17}H_{15}N_3I_2$ aq is obtained by heating MeI (2 pts.) with MeOH (2 pts.) and rosaniline (1 pt.) at 160° (Hofmann a. Girard, B. 2, 440). The zinc double chloride forms a bluish-green aqueous solution, turned reddish-yellow by hydrochloric acid, and rendered colourless by caustic soda. It dyes silk green. When heated strongly in the dry state it becomes violet. Its absorption-spectrum has been studied by Hartley (C. J. 51, 175). Iodine green may be reduced to penta-methyl-tri-amido-di-phenyl-tolyl-methane $NMe_2.C_6H_4.Me.CH(C_6H_4.NMe_2)(C_6H_4.NHMe)$ [178°] (O. Fischer a. G. Körner, B. 16, 2910). Besides the bodies here described other methylated rosanilines are doubtless formed in the methylation of rosaniline.

DI-METHYL-AMIDO-PHENYL-*p*-TOLYL SULPHONE $C_{17}H_{15}NSO_2$, i.e. [4:1] $C_6H_4.Me.SO_2.C_6H_4.NMe_2$. [95°]. From $C_6H_4.Me.SO_2Cl$ and dimethylaniline (Michler a. Meyer, B. 12, 1793). Split up by HCl at 180° into MeCl, aniline, H_2SO_4 , and toluene. Zinc and H_2SO_4 reduce it to *p*-tolyl mercaptan and dimethylaniline.

DI-METHYL-*p*-AMIDO-PHENYL-UREA $C_{17}H_{15}N_3O$ i.e. $NH_2.CO.NH.C_6H_4.NMe_2$. [179°]. From potassium cyanate and di-methyl-*p*-phenylene-diamine (Binder, B. 12, 536). Long needles, sol. hot water. — $B''H_2PtCl_6$: yellow leaflets.

Tetra-methyl-di-*p*-amido-di-phenyl-urea $C_{17}H_{15}N_3O$ i.e. $CO(NH.C_6H_4.NMe_2)_2$. [262°] (B.); [246°] (M. a. Z.). Obtained by heating urea with di-methyl-*p*-phenylene-diamine (Binder, B. 12, 535). The same body is apparently obtained by the action of $COCl_2$ on di-methyl-*p*-phenylene-diamine (Michler a. Zimmermann, B. 14, 2179). — $B''H_2Cl_2$: soluble crystalline powder. — $B''H_2SO_4$: sl. sol. water. — $B''H_2PtCl_6$.

METHYL-AMIDO-PROPANE SULPHONIC ACID $NHMe.CH_2.CHMe.SO_3H$. [220°-223°]. From methyl-propylene- ψ -thio-urea and bromine-water (Gabriel, B. 22, 2989). Colourless columns, v. s. sol. water.

METHYL- α -AMIDO-PROPIONIC ACID $C_6H_4NO_2$ i.e. $CH_3.CH(NHMe).CO_2H$. [260°]. From α -chloro-propionic ether and aqueous methylamine at 130° (Lindenburg, J. pr. [2] 12, 244). Prisms. Decomposed on fusion. Tastes sweet. Its copper salt crystallises in dark-blue prisms. — $HA'HCl$. [110°]. Deliquescent prisms. $HA'H_2PtCl_6$: triclinic prisms. — $HA'HNO_2$. [126°]. Monoclinic prisms.

Di-methyl- α -amido-propionic acid. *Methylochloride* $CH_3.CH(NMe_2)CO_2H$. Formed by treating α -chloro-propionic ether with trimethylamine, saponifying the resulting ether with baryta, and adding HCl (Brühl, B. 9, 34). Very hygroscopic, forming $(C_6H_4.NO_2.Cl)_2PtCl_6$ crystallising in roseate prisms, and $C_6H_4.NO_2AuCl_4$ crystallising in golden needles. The corresponding *Anhydride* of the *Methylo-hydroxide* $CH_3.CH<CO>O$ or 'betaine' is formed on adding baryta to the methylo-chloride and subsequently neutralising with H_2SO_4 . It forms extremely deliquescent crystals, and is neutral in reaction. The iodide $(C_6H_4.NO_2)_2HI$ forms long colourless prisms, v. sol. alcohol and hot water.

DI-METHYL-AMIDO-PROPYL ALCOHOL v. **DI-METHYL-OXY-PROPYL-AMINE**.

Tetra-methyl-*s*-di-amido-isopropyl alcohol $C_6H_4.N_2O$ i.e. $(NMe_2.CH_2)_2CH.OH$. (170°-185°). Formed from di-chloro-isopropyl alcohol (*s*-dichlorhydrin) and NMe_2H at 60° (Berend, B. 17, 510). Liquid, v. s. sol. water. — $B''H_2PtCl_6$: yellow plates.

Benzoyl derivative $(NMe_2.CH_2)_2CH.OBz$. Forms a platino-chloride $B''H_2PtCl_6$ crystallising in tables.

DI-METHYL-AMIDO-PROPYLENE GLYCOL $C_6H_4.NO_2$ i.e. $NMe_2.CH_2.CH(OH).CH_2.OH$. (217°). From dimethylamine and chloro-propylene glycol (chlorhydrin) (Roth, B. 15, 1153). Thick syrup; v. s. sol. water, alcohol, and ether. — $B''H_2PtCl_6$.

Methylo-chloride $NMe_2.Cl.CH_2.CH(OH).CH_2(OH)$. From the chlorhydrin and NMe_2 at 100° (V. Meyer, B. 2, 186; Hanriot, A. Ch. [5] 17, 99). Needles, v. s. sol. water. — $(C_6H_4.NO_2.Cl)_2PtCl_6$: crystalline tables. — $C_6H_4.NO_2AuCl_4$. [190°]. Orange crystals, m. sol. alcohol.

Di-benzoyl derivative $NMe_2.CH_2.CH(OBz).CH_2(OBz)$: oil. — Picrate $B''C_6H_4(NO_2)_2.OH$. [100°]. Laminæ (Roth, B. 15, 1153).

DI-METHYL-(B. 2)-AMIDO-QUINOLINE $NMe_2.O : CH.C_6H_4.N : CH$. [56°]. $C_6H_4(NMe_2)N$ i.e. $CH:CH.C_6H_4.N : OH$.

(O.); [58°] (O.). (s. 335°). Prepared by boiling a mixture of *u*-di-methyl-*p*-phenylene-diamine (25 pts.), glycerine (60 pts.), nitro-benzene (15 pts.), and H_2SO_4 (50 pts.) (La Coste, B. 16, 672). Colourless crystals. V. sol. alcohol, ether, and benzene.

Picrate $B''(C_6H_4(NO_2)_2.OH)$: very fine orange needles [215°].

Methylo-iodide $B''MeI$: long red needles. — $(BMeCl)_2PtCl_6$.

Methylo-chloride $B''MeCl$ aq. [244°]. Long scarlet hygroscopic needles (Ostermayer, B. 18, 596).

Methylo-chloride of the tetrahydride $NMe_2.C_6H_4.NMeCl$ aq: [220°], fine colourless needles. With ICl it forms $NMe_2.C_6H_4.NMeCl.ICl$: [127°], separating in small yellow crystals (Ostermayer, B. 18, 596).

TETRA-METHYL-DI-AMIDO-QUINONE $C_6H_4(NMe_2)_2O_2$. [174°]. Red tables. Formed by dissolving ordinary quinone in aqueous dimethylamine (Mylius, B. 18, 467).

DI-METHYL-AMIDO-SULPHO-BENZOIC ACID $C_6H_4(NMe_2)(SO_3H).CO_2H$ [4:2:1]. Obtained by heating the silver salt of amido-sulphobenzoic acid with MeI and MeOH at 100° (Hedrick, Am. 9, 413). Easily soluble crystals. — CaA'' . — $BaEt_2A''$.

TETRA-METHYL-DI-AMIDO-THIOBENZOPHENONE $C_6H_4.N_2S$ i.e. $CS(O_2H.NMe_2)_2$. [194°] (B.); [202°] (G.). S. (alcohol) -0.72 at 18° . S. (ether) -0.27 at 18° . S. (chloroform) -4.58 at 18° . Formed by passing H_2S into an alcoholic solution of the hydrochloride of tetra-methyl-di-amido-benzophenone imide (auramine) at 60° (Fehrmann, B. 20, 2857; Baither, B. 20, 1731, 3289). Formed also by the action of CS_2 on auramine (Graebe, B. 20, 3266). Obtained also from $CSCl_2$ and dimethylaniline. Ruby-red crystals, with blue lustre. Insol. water and light petroleum, sl. sol. other solvents. [194°]

solutions in benzene and CS_2 are dark red with green fluorescence.

Reactions.—1. Hot dilute hydrochloric acid gives H_2S and tetra-methyl-di-amido-benzophenone. — 2. Water at 120° under pressure also forms $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$. — 3. Boiling concentrated nitric acid forms $\text{CO}(\text{C}_6\text{H}_4(\text{NO}_2)_2\text{NMe}.\text{NO}_2)_2$, whence hydroxylamine hydrochloride forms $\text{CO}(\text{C}_6\text{H}_4(\text{NO}_2)_2\text{NMeH})_2$, [c. 196°]. — 4. By heating with excess of benzyl chloride it is converted into $\text{CCl}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$, a greyish-green powder, decomposed by water with production of $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$. — 5. Aniline hydrochloride at 150° forms phenyl-auramine $\text{NPh}:\text{C}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ [171°]. — 6. Phenyl-hydrazine at 100° forms $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$. Aniline at 150° also forms this ketone. — 7. Hydroxylamine gives the oxim of tetra-methyl-di-amido-benzophenone. — 8. Distillation over red hot zinc dust yields di-methyl-aniline and tetra-methyl-di-amido-di-phenyl-methane. — 9. Acetyl chloride in the CS_2 solution forms $\text{C}_{12}\text{H}_{18}\text{N}_2\text{S}.\text{AcCl}$, which forms a red alcoholic solution and a greenish-yellow solution in benzene. It begins to decompose at 160° . — 10. Benzoyl chloride in CS_2 forms a similar compound $\text{C}_{12}\text{H}_{18}\text{N}_2\text{SBzCl}$, which is insol. water, but decomposed by solution in alcohol. — 11. Boiling with Ac_2O and NaOAc forms $\text{C}_{12}\text{H}_{18}\text{N}_2\text{SO}_4$, a dark-grey powder. — 12. Methyl iodide appears to give $\text{C}_{12}\text{H}_{18}\text{N}_2\text{SMel}$, which forms green plates with coppery lustre, decomposes at 108° , and yields a deep bluish-green aqueous solution with red fluorescence. It dyes silk green. — 13. CSCl_2 , acting on its CS_2 solution forms a black powder, probably $\text{C}_{12}\text{H}_{18}\text{N}_2\text{SCSCl}_2$. In chloroform solution, CCl_4 forms white crusts of $\text{CCl}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2.\text{CHCl}_3$.

METHYL-AMIDO-THYMOQUINONE

$\text{C}_{11}\text{H}_{15}\text{NO}_2$, i.e. $\text{C}_6\text{H}_4\text{C}_2\text{HMe}(\text{NHMe})\text{O}_2$. [74°]. From methylamine and thymoquinone in alcoholic solution (Zincke, B. 14, 97). Dark-violet laminae (from very dilute alcohol). Volatile with steam. M. sol. water, v. e. sol. alcohol. The solutions are deep violet. Alcoholic HCl converts it into methylamine and oxythymoquinone.

Di-methyl-amido-thymoquinone $\text{C}_{12}\text{H}_{17}\text{NO}_2$, i.e. $\text{C}_6\text{H}_4\text{C}_2\text{HMe}(\text{NMe}_2)\text{O}_2$. Prepared by mixing dimethylamine with thymoquinone in alcoholic solution (Schulz, B. 16, 899). Dark-coloured oil. Volatile with steam. Split up by heating with dilute HCl into oxythymoquinone and dimethylamine.

Di-methyl-di-amido-thymoquinone $\text{C}_{12}\text{H}_{17}\text{N}_2\text{O}_2$, i.e. $\text{C}_6\text{H}_4\text{C}_2\text{Me}(\text{NMe})_2\text{O}_2$. [203°]. Formed, together with methyl-amido-thymoquinone, by treating a cold concentrated alcoholic solution of thymoquinone with methylamine (Zincke). Formed also by the action of methylamine on di-bromo-thymoquinone. Long reddish-violet needles (from alcohol). Decomposed by KOH or H_2SO_4 in alcoholic solution into methylamine and di-oxy-thymoquinone.

METHYL-AMIDO-TOLUENE v. METHYL-TOLUIDINE.

Methyl-di-amido-toluene v. METHYL-TOLYL-DIAMINE.

Methyl-tri-amido-toluene $\text{C}_8\text{H}_7\text{N}_3$, i.e. $\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)_3(\text{NHMe})$. The hydrochloride $\text{B}^+\text{H}_2\text{Cl}_2$ is prepared by reducing the nitramine of di-nitro-methyl-o-toluidine with tin and

HCl (Van Romburgh, R. T. C. 3, 400). It forms small crystals.

Di-methyl-amido-toluene sulphonic acid $\text{C}_8\text{H}_7\text{N}_2\text{SO}_3$, i.e. $\text{NMe}_2\text{C}_6\text{H}_3\text{Me}.\text{SO}_3\text{H}$ [$2:1:4:7$]. Formed by heating di-methyl-o-toluidine (1 pt.) with H_2SO_4 (4 pts.) at 180° to 210° (Michler a. Sampaio, B. 14, 2168). Large glittering prisms (from water); insol. alcohol, v. sol. hot water. — CaA'_2 (dried at 130°). Nodules. — BaA'_2 (dried at 130°). Laminae; v. sol. hot water. — ZnA'_2 : needles.

TETRA-METHYL-DI-AMIDO-DITOLYL

$\text{NMe}_2\text{C}_6\text{H}_3\text{Me}.\text{C}_6\text{H}_3\text{Me}.\text{NMe}_2$. Tetra-methyl-toluidine. [80°]. Formed by oxidising di-methyl-o-toluidine with MnO_2 and dilute H_2SO_4 . Formed also by methylation of di-amido-ditolyl (Michler a. Sampaio, B. 14, 2170). White plates; sol. ether and hot alcohol, insol. water. — $\text{B}^+\text{H}_2\text{Cl}_2$: white needles. — $\text{B}^+\text{H}_2\text{PtCl}_2$: yellow crystalline pp.

Tetra-methyl-di-amido-ditolyl $\text{C}_{16}\text{H}_{22}\text{N}_2$, i.e. $\text{NMe}_2\text{C}_6\text{H}_3\text{Me}.\text{C}_6\text{H}_3\text{Me}.\text{NMe}_2$. [190°]. Formed in small quantity by heating dimethyl-o-toluidine with H_2SO_4 (M. a. S.). Long needles; sol. hot alcohol, ligroin, and ether, insol. water. Gives a green colouration with Fe_2Cl_6 and yellow colour with CrO_3 .

Tetra-methyl-di-amido-ditolyl (?) $\text{C}_{11}\text{H}_{12}\text{N}_2$, i.e. $\text{NMe}_2\text{C}_6\text{H}_3\text{Me}.\text{C}_6\text{H}_3\text{Me}.\text{NMe}_2$. [57°]. Prepared by heating dimethyl-p-toluidine with H_2SO_4 (Michler a. Pattinson, B. 14, 2167). White needles; sol. alcohol and ether, insol. water. — $\text{B}^+\text{H}_2\text{Cl}_2.\text{PtCl}_2$.

DI-METHYL-AMIDO-TOLYL-BUTANE $\text{C}_{12}\text{H}_{17}\text{N}$, i.e. $\text{C}_6\text{H}_4\text{C}_2\text{H}_2\text{Me}.\text{NMe}_2$. [251°]. From amido-tolyl-butane and MeI (Effront, B. 17, 2339). — $\text{B}^+\text{H}_2\text{PtCl}_2$.

DI-METHYL-AMIDO-TOLYL METHYL KETONE

$\text{C}_{11}\text{H}_{15}\text{NO}$, i.e. [$1:2:5$] $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NMe})_2.\text{CO}.\text{CH}_3$. [95°]. Flat yellowish prisms; e. sol. alcohol, ether, and hot water, nearly insol. petroleum-ether. Formed by methylation of amido-tolyl methyl ketone (Klingel, B. 18, 2699).

METHYL- α -AMIDO-n-VALERIC ACID

$\text{C}_8\text{H}_{13}\text{NO}_2$, i.e. $\text{CH}_3.\text{CH}_2.\text{CH}_2.\text{CH}(\text{NHMe}).\text{CO}_2\text{H}$. Obtained by heating butyric aldehyde with conc. aqueous HCy , adding methylamine, and heating again. The nitrile then separates as an oil, which is hydrolysed by prolonged boiling with dilute HCl aq (Menozzi a. Belloni, G. 17, 116). Long glistening needles (containing aq); decomposed partially at 110° with formation of a sublimate.

Salts.— $\text{CuA}'_2.2\text{aq}$: blue prisms. — $\text{HA}'\text{HNO}_2$: prisms, v. sol. water.

Methyl- α -amido-isovaleric acid $\text{C}_8\text{H}_{13}\text{NO}_2$, i.e. $(\text{CH}_3)_2\text{CH}.\text{CH}(\text{NHMe}).\text{CO}_2\text{H}$. Formed by boiling α -bromo-isovaleric acid with aqueous methylamine (Duvillier, C. R. 88, 425; A. Ch. [5] 21, 434). White crystalline powder; v. e. sol. water, th. sol. hot alcohol, insol. ether. Neutral in reaction. With cyanamide it forms a creatinin $\text{C}_8\text{H}_{13}\text{N}_3\text{O}$, crystallising in slender needles, v. sol. boiling alcohol (Duvillier, C. R. 95, 456). — $\text{HA}'\text{HCl}$. Crystallises with difficulty. — $\text{H}_2\text{A}'_2.\text{H}_2\text{SO}_4$: prisms; v. sol. water. — $\text{HA}'\text{HAuCl}_4$ aq: short trimetric prisms. The copper salt forms an intense blue solution.

Di-methyl- α -amido-isovaleric acid. Methyl-o-iodide of the methyl ether.

Pr.CH(NMe₂)₂.CO.Me. Formed by heating MeI (4 pts.) with zinc amido-valerate (1 pt.) and ZnO (1 pt.) at 110° for 16 hrs. (Duvillier, *C. R.* 110, 640). Yields {Pr.CH(NMe₂Cl).CO₂H}₂.PtCl₄aq and Pr.CH(NMe₂Cl).CO₂H.aqCl.

METHYLAMINE CNH₂, i.e. CH₃.NH₂. Mol. w. 31. (-6°) (Hofmann, *B.* 22, 701). S.G. -193-699. H.F.p. 9,540. H.F.v. 8,380 (Thomsen, *Th.*). H.C. 256,900 (Müller, *Bl.* [2] 44, 609). *Heat of neutralisation* by HCl: 25,900 (Müller, *A. Ch.* [6] 15, 531). S. (gas) 1150 at 12.5°; 950 at 25°.

Occurrence.—1. In bone oil (Anderson, *A.* 80, 44).—2. In *Mercurialis annua* and *M. perennis* (Schmidt, *B.* 10, 2226; *A.* 193, 73; cf. Reichardt, *Z.* 1868, 734).—3. In herring-brine (Bocklisch, *B.* 18, 1922).—4. In crude wood spirit (G. Williams, *Chem. Gaz.* 1853, 409; Commaille, *J.* 1873, 686; Vincent, *C. R.* 77, 898).—5. In the product of the distillation of beet-root molasses (Duvillier a. Buisine, *A. Ch.* [5] 23, 317).—6. In the 'yolk' or 'suint' of sheep. When an aqueous extract of this substance is allowed to stand for some time, and is then boiled, it gives off 4 pts. of NH₃.Me for 95 pts. of NH₃ and 1 pt. of NMe₂ (Buisine, *C. R.* 104, 1292).

Formation.—1. Discovered by Wurtz, who obtained it by distilling methyl cyanate (or cyanurate) with potash (*C. R.* 28, 223, 323; *A. Ch.* [3] 30, 443).—2. By decomposing methylurea with potash (Wurtz).—3. In small quantity, together with NHMe₂ and NMe₂, by heating ammonia with MeI (Hofmann, *A.* 79, 19). Formed also by heating the methyl ethers of other inorganic acids with ammonia.—4. By heating wood spirit with ammonium chloride or iodide at 300° (Berthelot, *J.* 1852, 551; Girard, *Bl.* [2] 24, 121; cf. Weith, *B.* 8, 458). By heating methyl alcohol (3 pts.) with NH₄Cl (2 pts.) and HCl (1 pt.) at 207° for 30 hours Dusart a. Bardy converted one-third of the NH₃ into NH₂.Me (*C. R.* 74, 188).—5. By heating methyl alcohol with ammoniacal ZnCl₂ (Gasirowsky, *Z.* 17, 639).—6. By heating morphine or codeine with KOH (Wertheim, *A.* 73, 210; Anderson, *A.* 77, 374).—7. By distilling glycocoll with BaO (Cahours, *A.* 109, 28).—8. By the action of chlorine on theobromine or caffeine (Rochleder a. Hlasiwetz, *J.* 1850, 434, 437).—9. In small quantity by reducing HCy with zinc and dilute H₂SO₄ (Mendius, *A.* 121, 129).—10. By passing a mixture of HCy and hydrogen over platinum-black at 110° (Debus, *A.* 128, 200).—11. By reducing nitro-methane with iron filings and dilute HOAc (L'reibisch, *J. pr.* [2] 7, 480).—12. By digesting di-methyl-uric acid with HClAq for several hours at 170° (Hill a. Mabery, *Am.* 2, 310).

Preparation.—1. By distilling methyl cyanurate with aqueous KOH (Wurtz). The distillate is received in dilute HCl, and the methylamine hydrochloride dried and distilled with quicklime. 2. A mixture of acetamide (1 mol.) and bromine (1 mol.) is treated in the cold with a 10 p.c. solution of KOH till nearly decolourised. The solution of methyl-bromo-amide thus obtained is then run in a slow stream into a 30 p.c. solution of 8 mols. of KOH heated to 60°-70° and digested for 10 or 15 mins. till decolourised. The solution is then boiled and the methylamine received in HCl; the yield is 87 p.c. of the theoretical (Hofmann, *B.* 15, 765; 18, 2741).—

3. Methyl nitrate (1 mol.) is heated in closed vessels at 100° with a solution of ammonia (1 mol.) in wood spirit. Besides the nitrate of mono-methyl-amine there is formed tetra-methyl ammonium nitrate together with small quantities of di- and tri-methylamine nitrates. At the end of the reaction the product is neutralised with sulphuric acid, heated to evaporate off the alcohol, and the residue decomposed by potash, and the bases received in hydrochloric acid. The hydrochlorides are treated with absolute alcohol to remove the ammonium chloride, and again decomposed, the bases being received in sulphuric acid. The sulphates are then treated with absolute alcohol in which mono-methylamine sulphate is insoluble. To remove the last traces of impurities the insoluble sulphate is again decomposed and converted into di-methyl-oxamide, which yields on decomposition pure mono-methyl-amine (Duvillier a. Buisine, *A. Ch.* [5] 23, 322; cf. Juncadella, *C. R.* 48, 342).—4. By the action of tin and HCl on chloropiricin (Wallach, *A.* 184, 51; cf. Geisse, *A.* 109, 282).—5. By heating dry ammonium methyl-sulphate at 300° and distilling the product with potash (Milner Morrison, *Pr. F.* 10, 275).

Properties.—Colourless gas with strong ammoniacal odour. Not solid at -75°. Turns red litmus blue. Fumes strongly with HCl. Rapidly absorbed by water and by charcoal. Of all known gases it is the most soluble in water. Burns in air with livid yellowish flame (difference from NH₃). The aqueous solution of methylamine is extremely caustic, and gives off the gas when boiled. It ppt. metallic salts, for the most part in the same manner as ammonia. Zinc hydroxide is, however, soluble in a large excess of methylamine. With cupric salts it gives a bluish-white pp. dissolving in excess and forming a deep-blue solution. With salts of Cd, Ni, and Co it forms pps. insoluble in excess (difference from NH₃). It ppts. lead nitrate but not lead acetate. With mercurous nitrate it gives a black pp.; with HgCl₂ a white pp.; with AgNO₃ it gives a pp. of Ag₂O soluble in excess. It dissolves AgCl. With chloride of gold it gives a brownish-yellow pp. soluble in excess. Platinic chloride gives a yellow crystalline pp.

Reactions.—1. Passage through a red-hot tube converts it into hydrogen, CH₄, ammonia, and HCy. No acetylene, benzene, or C₂H₂ is formed (Müller, *Bl.* [2] 45, 438). When an aqueous solution of methylamine is set on fire, HCy is found in the residue (Tollens, *Z.* [2] 2, 516).—2. Heated potassium forms hydrogen and KCy.—3. Cyanogen chloride forms methyl-cyanamide (Cahours a. Cloëz, *C. R.* 88, 354).—4. Iodine forms MeNI₂.—5. CO₂ forms methylamine methyl-carbamate.—6. According to Berthelot, heating with saturated HIAq yields ammonia and CH₄.—7. COCl₂ yields NHMe.COCl [90°].—8. Liquid MeCl under pressure, forms NMe₂Cl and NMe₂H.Cl (Vincent a. Chappuis, *C. R.* 102, 436).—9. MeBr (1 mol.) in MeOH at 100° forms, chiefly, NMe₂Br. In like manner MeI forms NMe₂I (Duvillier a. Buisine, *C. R.* 90, 1426).—10. Benzoic aldehyde added to aqueous NMe₂H, forms PhCH.NMe₂ an oil (α. 180°) which yields benzyl-methylamine (185°) on reduction (Zaun-schirm, *A.* 245, 281).—11. *o*-Oxy-benzoic aldehyde forms C₆H₅NO (229°) (Dennstedt a. Zimmer-

mann, *B.* 21, 1553).—12. 'Dicynanamidobenzoyl' (cf. vol. i. p. 155) forms small needles of $C_{10}H_{11}N_3O_2$ (Griess, *B.* 18, 2420).—13. *Diazo-benzene chloride* added to a cool 33 p.c. solution of methylamine forms $MeN(N_2Ph)_2$ [113°] which crystallises in yellow needles, v. sol. ether, m. sol. alcohol. It is reduced by Zn and HOAc to methylamine and phenylhydrazine. Boiling dilute H_2SO_4 gives nitrogen, aniline, MeOH, phenol, and some $PhN_2C_6H_5NH_2$ (Goldschmidt & Badl, *B.* 22, 934).—14. *o-Diazo-anisole chloride* forms yellow needles of the compound $MeN(N_2C_6H_4OMe)_2$ [141°] (G. a. B.).—15. *p-Diazo-anisole chloride* forms $MeN(N_2C_6H_4OMe)_2$ [112°] (G. a. B.).—16. *p-Diazo-toluene chloride* forms $MeN(N_2C_6H_4Me)_2$ [147°].

Salts.— B^+HCl . Large deliquescent laminae (from water), may be sublimed. Sol. alcohol, insol. $CHCl_3$.— B^+HAuCl , aq. Trimetric crystals (Topsøe, *J.* 1893, 618).— B^+HAuCl_2 . Monoclinic (T.).— $B^+H_2PtCl_6$. Golden hexagonal scales (Lüdecke, *J.* 1890, 511). S. 2 at 14°. Insol. alcohol, not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).— $B^+H_2Cl_2PtBr_4$. Scarlet crystals (Maly & Hinterberger, *M.* 3, 89).— B^+PtCl_6 . Insoluble green powder.— B^+PtCl_4 . V. e. sol. water.— $B^+H_2IrCl_6$. Small hexagonal brownish-black plates (Vincent, *Bl.* [2] 43, 154).— $B^+H_2Rh_2Cl_{11}$ (Vincent, *C. R.* 101, 322).— $B^+H_2HgCl_4$. Monoclinic crystals, v. sol. water.— B^+HHgCl_4 . Rhombohedral crystals (T.).— $B^+H_2CuCl_4$. Trimetric crystals.— $B^+H_2PdCl_4$.— B^+HBr . Large deliquescent plates (from alcohol), v. sol. water and alcohol.— B^+HI .— $B^+H_2I_3BiI_3$. Scarlet pp. (Krant, *A.* 210, 312).— $B^+H_2I_3BiI_3$. Crystalline pp. (K.).— B^+HNO_3 . Elongated trimetric prisms. Deliquescent, v. sol. water, sl. sol. cold alcohol. [100°] (Franchimont, *R. T. C.* 2, 338).— $B^+H_2SO_4$. Deliquescent needles, insol. alcohol.— B^+HMeSO_4 . Crystals, v. e. sol. water (Claesson & Lundvall, *B.* 13, 1701).— B^+HVO_3 (Bailey, *C. J.* 45, 692).— B^+HVO_3 , aq. Colourless acicular crystals (Ditto, *C. R.* 104, 1844).— $B^+(H_2O)(V_2O_5)_2$ aq. Yellow powder (D.).— $B^+(H_2O)_2(V_2O_5)_2$ aq (B.).— $B^+H_2CO_3$. Formed, together with methyl-carbamate $NMeH.CO_2H$, by decomposing $CaCO_3$ with methylamine hydrochloride. Deposited in crystals from the liquid distillate.— $B^+H_2C_2O_4$. Prisms, v. sol. water, insol. alcohol.—Benzene sulphonate [147°] (Norton & Westenhoff, *Am.* 10, 129).—Valerate $NH_2Me_2CMe_2CO_2H?$ [81°]. (175°). From NH_2Me and tri-methyl-acetic acid at 150° (Franchimont & Klobbie, *R. T. C.* 6, 234).

Acetyl derivative C_3H_7NO i.e. $NMeAcH$. *Methyl-acetamide*. [28°]. (206°). From $EtOAc$ and aqueous methylamine at 150° (Hofmann, *B.* 14, 2725).— $NMeAcHHNO_3$. [58°]. Large hygroscopic crystals (Franchimont, *R. T. C.* 2, 341).

Di-acetyl derivative $C_6H_9NO_4$ i.e. $NMeAc_2$. (192°). A product of the action of Ac_2O on methyl-acetyl-urea (H.). Liquid, miscible with water. Split up by HCl into methylamine and acetic acid.

Tri-chloro-acetyl derivative $CCl_3.CO.NHMe$. [106°]. From CCl_3CO_2Et and aqueous methylamine (Franchimont & Klobbie, *R. T. C.* 6, 284). White crystals, sl. sol. water and ether. Slowly attacked by pure HNO_3 , which gives off N_2O .

Valeryl derivative $CMe_3.CO.NHMe$. [91°]. (204°). V.D. 3.98. From $Me_3C.COCl$ and NH_2Me . Methylamine and $Me_3C.CO_2Me$ yield only $(Me_3C.CO_2H)_2NH_2Me$. V. sol. water and alcohol (F. a. K.). Pure HNO_3 gives off N_2O .

Heptoyl derivative $C_7H_{15}.CO.NHMe$. [9°]. (266°). S.G. 1.2.895. Thick liquid (F. a. K.).

Benzoyl derivative $C_6H_5.CO.NHMe$. [78°]. Crystallises from alcohol (Romburgh, *R. T. C.* 4, 388).

o-Amido-benzoyl derivative $C_6H_4(NH_2).CO.NHMe$. [80°]. From isoitoic acid and methylamine solution (Weddige, *J. pr.* [2] 36, 150). Thick prisms (from benzene), v. e. sol. alcohol and ether, sol. hot water. Ac_2O gives $C_6H_4(NHAc).CO.NHMe$ [172°]. $BzCl$ forms $C_6H_4(NH_2Bz).CO.NHMe$ [181°] (Körner, *J. pr.* [2] 36, 159).

Other alkoyl derivatives are described under the acids from which they are derived.

Methyl-di-chloro-amine $CH_3.NCl_2$. (60° uncor.). Pungent yellow liquid (Köhler, *B.* 12, 770).

Methyl-di-bromo-amine $CH_3.NBr_2$. Formed by the action of bromine and potash on methylamine hydrochloride (Hofmann, *B.* 15, 767). Extremely pungent liquid. Slowly converted into methylamine by HCl .

Methyl-di-iodo-amine $CH_3.NI_2$. Formed by the action of iodine on aqueous methylamine (Wurtz, *A. Ch.* [3] 30, 455). Prepared by adding iodine (1g.) and water (50g.) to methylamine hydrochloride, and then adding aqueous $NaOH$ (Raschig, *A.* 230, 221). Brownish-red pp.; quickly becoming brick-red. Completely soluble in aqueous HCl , soon decomposing into methylamine and ICl . Ammonia forms $NMeH_2$ and NH_4I . Cold potash dissolves it, forming methylamine, KIO_3 , and KI .

Methyl-nitro-amine $CH_3.NH.NO_2$. [38°]. Obtained by treating methyl chloroformate with methylamine, nitrating the resulting methyl methyl-carbamate $CH_3NH.CO.OMe$, and boiling the product with ammonia (Franchimont & Klobbie, *R. T. C.* 7, 354; 8, 297). Formed also by decomposing $NO_2.NMe.CO.CO.NMe.NO_2$ with aqueous ammonia. Colourless needles, sol. alcohol. Strongly acid in reaction. Converted by KOH and MeI into crystalline $Me_2N.NO_2$.— $KMeN.NO_2$. Slender needles, sol. alcohol and water.

Dimethylamine C_2H_7N i.e. $(CH_3)_2NH$. Mol. w. 45. (7.2°) (Hofmann, *B.* 22, 702). S.G. 0.687. S.V. 152.4 (Ramsay). H.F.p. 12.720 (Thomson); 3,500 (Muller, *Bl.* [2] 41, 609). H.F.v. 10,980 (Thomson, *Th.*). H.C. 42,600 (M.). Heat of neutralisation (by HCl): 23,980 (Müller, *A. Ch.* [6] 15, 531).

Occurrence.—In herring-brine (Bocklisch, *B.* 18, 1924).

Formation.—1. One of the products of the action of MeI on ammonia (Hofmann).—2. A mixture of mono-, di-, and tri-methyl-amine is obtained by heating methyl alcohol with ammoniacal $ZnCl_2$ at 200°–220° (Merz & Gasiorowski, *B.* 17, 639).—3. In small quantity by heating the sulphite of aldehyde-ammonia in a sealed tube, or by distilling it with lime (Petersen, *A.* 102, 817).

Preparation.—1. The mixture of iodides obtained by heating ammonia with MeI is distilled with potash, and the evolved bases dried by KOH and condensed by a freezing mixture, the bases NMe_2 , NMe_2H , and NMe_2H_2 being separated by means of oxalic ether (Hofmann, *Pr.* 12, 380).—2. The bases obtained from MeBr and NH_3 are treated with nitrous acid, and the dimethylnitrosamine decomposed by HCl and distilled over sodium (Hofmann).—3. Nitroso-dimethyl-aniline hydrochloride (2 pts.) is boiled with water (90 pts.) and aqueous NaOH (10 pts. of S.G. 1.25) (Baeyer a. Caro, *B.* 7, 964; 8, 616).

Properties.—Highly alkaline liquid or gas. Has not been solidified. If to an alcoholic solution of the base picryl chloride $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{Cl}$ be added, and then H_2SO_4 followed by water, there is formed a characteristic yellow pp. of tri-nitro-di-methyl-aniline (Van Romburgh, *R. T. C.* 2, 106).

Reactions.—1. MeCl forms only NMe_2Cl and NMe_2HCl (Vincent a. Chappuis, *C. R.* 102, 436).—2. SO_2Cl_2 forms oily $\text{NMe}_2\text{SO}_2\text{Cl}$ (183°–187°) and $\text{SO}_2(\text{NMe}_2)_2$ (Behrend, *B.* 14, 1810).—3. Cyanamide heated with NHMe at 110° forms di-methyl-guanidine (Tatarinoff, *C. R.* 89, 608). 4. *p*-Diazotoluene chloride forms $\text{NMe}_2\text{N}_2\text{C}_6\text{H}_4$ [46°] (Goldschmidt a. Badl, *B.* 22, 935).

Salts.— B^+HCl . V. sol. chloroform (difference from NH_4Cl and NMe_2HCl (Behrend, *B.* 15, 1611; *A.* 222, 119).— B^+HAuCl_4 . Monoclinic needles. — $\text{B}^+\text{H}_2\text{PtCl}_6$. Trimetric needles. — $\text{B}^+\text{H}_2\text{IrCl}_6$. Trimetric octahedra; *a:b:c* = 1.969:1.1:0.954 (Vincent, *Bl.* [2] 43, 154). — $\text{B}^+\text{Rh}_2\text{Cl}_{12}$ 8aq. Large dark garnet-red prisms (Vincent, *Bl.* [2] 44, 513; *C. R.* 101, 322). — $\text{B}^+\text{H}_2\text{HgCl}_4$. Monoclinic crystals (Topsoe, *J.* 1883, 618). — B^+HHgCl_4 . Monoclinic crystals (T.). — $\text{B}^+\text{H}_2\text{HgCl}_4$. Triclinic crystals. — $\text{B}^+\text{H}_2\text{SnCl}_6$. Trimetric tables (Hjortdahl, *J.* 1882, 474). — $\text{B}^+\text{H}_2\text{CuCl}_4$. Crystals. — B^+HCuCl_4 . Monoclinic crystals (T.). — B^+HBr . — $\text{B}^+\text{H}_2\text{PtBr}_6$. Trimetric needles. — $\text{B}^+\text{H}_2\text{I}_3\text{BiI}_4$. — $\text{B}^+\text{H}_2\text{I}_2\text{BiI}_4$ (Kraut, *A.* 210, 314). — B^+HNO_3 [74°]. Long hygroscopic needles or prisms. V. sol. alcohol (Franchimont, *R. T. C.* 2, 338; 3, 229). Decomposed by heat, yielding nitrogen, CO_2 , and dimethylamine (Romburgh, *R. T. C.* 5, 246). — B^+HVO . (Bailey, *C. J.* 45, 693). — $\text{B}^+(\text{H}_2\text{O})_2(\text{V}_2\text{O}_5)_4$ 4aq. — Benzene sulphonate [510°] (Norton, *Am.* 10, 129). — *p*-Toluene sulphonate [78°] (N.).

Acetyl derivative NMe_2Ac . (166°). S.G. 22.941. From dimethylamine and AcCl dissolved in ether (Franchimont, *R. T. C.* 2, 121, 342). Colourless liquid. Fuming HNO_3 forms in the cold NMe_2NO_2 [57°].

Tri-chloro-acetyl derivative $\text{CCl}_3\text{CO.NMe}_2$ [104°] (C.). S.G. 1.441 (F. a. K.). From $\text{CCl}_3\text{CO.CCl}_4$ and NMe_2 (Cloëz, *A. Ch.* [6] 9, 145).

Heptyl derivative $\text{C}_6\text{H}_{13}\text{CO.NMe}_2$ (243°). S.G. 12.894. Solidifies below -10° (Franchimont a. Klobbie, *R. T. C.* 6, 549). With HNO_3 it gives di-methyl-nitro-amine.

Valeryl derivative $\text{CMe}_2\text{CO.NMe}_2$ (188°). S.G. 12.912. Liquid, v. sol. water. Not solidified at -17° . HNO_3 (S.G. 1.52) forms NMe_2NO_2 .

Benzoyl derivative $\text{C}_6\text{H}_5\text{CO.NMe}_2$ [42°]. (250° uncor.). Crystals, v. sol. water. Split up by aqueous HCl at 200° into HOBz and

HNMe_2 (Hallmann, *B.* 9, 846). Conc. HNO_3 gives $\text{C}_6\text{H}_5(\text{NO}_2)_3\text{CO.NMe}_2$ (Romburgh, *R. T. C.* 4, 385). With COCl_2 it forms deliquescent crystals of $\text{C}_6\text{H}_5\text{COCl.NMe}_2$ [38°] decomposed by water into HCl and $\text{C}_6\text{H}_5\text{CO.NMe}_2$.

Di-methyl-iodo-amine NMe_2I . From dimethylamine, iodine, and NaOH. Pale-yellow pp., which rapidly decomposes (Raschig, *A.* 230, 223).

Dimethylnitrosamine NMe_2NO (148° at 725 mm.). Formed by treating an aqueous solution of dimethylamine hydrochloride with potassium nitrite (E. Fischer, *B.* 8, 1587; Renouf, *B.* 13, 2169). Yellow oil. Volatile with steam. Reduced by zinc-dust and HOAc to di-methylhydrazine. Decomposed by boiling HCl into NMe_2H and nitrous acid. — B^+HCl : white needles, decomposed by water or alcohol.

Di-methyl-nitro-amine NMe_2NO_2 [57°]. From NMe_2Ac and HNO_3 (Franchimont). Large crystals.

Di-methyl-amine-tri-bromide Me_2NBr 2aq or $\text{Me}_2\text{N} \begin{smallmatrix} \text{Br} \\ \text{OH} \end{smallmatrix}$. Formed, as a yellow pp., on adding an excess of bromine-water to a cold solution of dimethylamine— $2\text{Me}_2\text{NH} + 4\text{Br} + 2\text{H}_2\text{O} = \text{C}_2\text{H}_5\text{NBr}_2\text{O}_2 + \text{Me}_2\text{NH}_2\text{Br}$. Yellow powder. Sol. alcohol and ether, v. sl. sol. water. It is very unstable: on keeping over-night in a closed vessel it liquefies to a brown fluid containing free bromine; but under water it can be kept for several days. Alkalis and acids decompose it at once; thus HCl gives dimethylamine hydrochloride according to the equation $\text{C}_2\text{H}_5\text{NBr}_2\text{O}_2 + 2\text{HCl} = \text{Me}_2\text{NH}_2\text{HCl} + 3\text{Br} + \text{Cl} + 2\text{H}_2\text{O}$ (Raschig, *B.* 18, 2249).

Trimethylamine $\text{C}_3\text{H}_7\text{N}$ i.e. NMe_3 . Mol. w. 59. (3.5°). S.G. 0.662 (Hofmann, *B.* 22, 703). H.F.p. 15,870 (Thomsen, *Th.*); 14900 (Müller, *Bl.* [2] 44, 609). H.F.v. 13,550. H.C. 577,600 (M.). Heat of neutralisation (by HCl) 17,900 (Müller, *A. Ch.* [6] 15, 531).

Occurrence.—In herring-brine (Hofmann, *C. J.* 5, 288; cf. Wertheim, *J.* 1851, 480). In the flowers of *Crataegus oxyacantha* (Wicke, *A.* 91, 121), *C. monogyna*, *Pyrus aucuparia*, and *P. communis* (Wittstein, *J.* 1854, 479). In the stinking goosefoot (*Chenopodium vulvaria*) (Des-saignes, *J.* 1851, 481); in *Arnica montana* (Hesse, *J.* 1864, 458); and in the seeds of the keech (Brandl a. Rakowiecki, *J.* 1864, 607). It also occurs in *Mercurialis annua* (E. Schmidt, *B.* 10, 2226). In human urine (Dessaignes, *A.* 100, 218), and in calves' blood which has stood 12 hours (Dessaignes, *J. Ph.* [3] 32, 48). In ergot of rye (Walz, *J.* 1852, 552; Rithausen, *Rép. chim. pur.* 1863, 420; cf. Brieger, *H.* 11, 184). In small quantity in guano (Hesse, *J.* 1857, 402). In bone oil (Anderson, *A.* 80, 51). According to Ludwig (*Z.* 4, 96) it occurs in small quantity in several Austrian and Hungarian wines. In the product of the destructive distillation of putrid brain (Selmi, *G.* 6, 468) and of beet-root molasses (Vincent, *C. R.* 84, 1189; 85, 667; *J. Ph.* [4] 30, 132; Roscoe, *C. N.* 89, 107). In the putrefaction of yeast (A. Müller, *J.* 1857, 402) and of wheat dough (Sullivan, *J.* 1853, 281). In most of the cases here mentioned the trimethylamine is probably obtained from betaine,

neurine, or lecithin, either by putrefactive decomposition or in the chemical treatment.

Formation.—1. Together with NMe_2 and NMe_3 by the action of ammonia on MeI , and separated by treatment with oxalic ether, with which it does not react (Hofmann, *C. J.* 4, 304). 2. By the distillation of NMe_2OH (Hofmann, *A.* 98, 826).—3. By heating narcotine with KOH at 280° (Wertheim, *A.* 73, 208).—4. By heating extract of calamus root with alkali (Thoms, *B.* 21, 1912).—5. By passing coal gas through heated zinc-dust (Williams, *C. N.* 51, 15).

Preparation.—1. The residues in the preparation of sugar from beet-root are, after fermentation, subjected to dry distillation. The aqueous portion of the distillate is neutralised by H_2SO_4 , ammonium sulphate separated by crystallisation, and, after evaporation, the trimethylamine expelled by an alkali. Commercial trimethylamine still contains methylamine, ethylamine, dimethylamine, propylamine, and isobutylamine. The proportion in which these bases are present varies greatly in different samples. To the aqueous solution of the bases oxalic ether is added, the primary bases being ppt. as di-alkyl-oxamides. The mother-liquor is distilled with addition of KOH and the dry bases dissolved in absolute alcohol. Oxalic ether is then added to the alcoholic solution, when the diamines are converted into di-alkyl-oxamic ethers, and the trimethylamine can be obtained by distillation (Vincent, *C. R.* 89, 238, 788; Duvillier a. Buisine, *C. R.* 89, 48, 709; 92, 250; *A. Ch.* [5] 23, 298; cf. Eisenberg, *B.* 13, 1669). 2. Perfectly pure trimethylamine is obtained by distilling NMe_2OH and rectifying over sodium (Hofmann, *B.* 22, 699).

Properties.—Gas with ammoniacal and fishy odour. Remains liquid at -75° . V. e. sol. water. When an aqueous solution is strongly cooled a hydrate $\text{NMe}_2\cdot 7\text{aq}$ [4 $^\circ$ 3'] separates.

Reactions.—1. KMnO_4 oxidises it to CO_2 and oxalic acid (Wallach a. Claisen, *B.* 8, 1237).—2. At a red heat it is converted into HCy and NH_3 (Willm, *Bl.* [2] 41, 449). Passed with hydrogen through a red-hot tube it yields NH_3 , cyanogen, hydrocarbons, and $\text{CH}_3(\text{NMe}_2)_2$ (Romeny, *B.* 11, 835).—3. CS_2 forms NMe_2CS_2 , crystallising in white needles [125°]. This body is m. sol. chloroform and dilute alcohol, nearly insol. absolute alcohol, CS_2 , and benzene. It splits up into its components, even at ordinary temperatures, but with dilute HCl it forms $\text{NMe}_2\text{CS}_2\text{HCl}$ and $(\text{NMe}_2\text{CS}_2)_2\text{H}_2\text{Cl}_2$. Conc. HCl aq splits it up into its components. Phosphoric acid forms $(\text{NMe}_2\text{CS}_2)_2\text{H}_2\text{PO}_4$ (Bleunard, *C. R.* 87, 1040).—4. Glycol chlorhydrin forms neurine chloride $\text{NMe}_2\cdot\text{ClCH}_2\cdot\text{CH}_2\cdot\text{OH}$.—5. Chloro-

acetic acid forms betaine $\text{CH}_3\text{NMe}_2\text{COO}$.

6. Dichlorhydrin of glycerin forms 'sepine' chloride $\text{C}_3\text{H}_7\text{Cl}(\text{OH})_2\text{NMe}_2\text{Cl}$ and 'aposepine' chloride $\text{C}_3\text{H}_7(\text{OH})(\text{NMe}_2\text{Cl})_2$ (Niemikovich, *M.* 7, 249).—7. Hexa-chloro-acetone forms $\text{CCl}_3\text{CO}\cdot\text{NMe}_2$ [1049] (Cloëz, *A. Ch.* [6] 9, 145). 8. When heated with aniline hydrochloride it yields a distillate of methyl-aniline.

Salts.— $\text{B}\cdot\text{HCl}$: decomposes at 285° , giving off NMe_2 and MeCl , and leaving mono- and dimethylamine hydrochlorides. At 805° ammonia

and methyl chloride are given off from the residue, and at 325° the whole has sublimed, the sublimate consisting of NH_4Cl and methylamine hydrochloride. This decomposition may be utilised for the manufacture of MeCl (Vincent, *C. R.* 84, 1139; 85, 666).— $\text{B}\cdot\text{HBr}$: decomposed between 230° and 300° into NMe_2 , ammonia, and MeBr .— $\text{B}\cdot\text{HI}$: white scales, decomposed between 210° and 280° into NMe_2 , ammonia, MeI , and a residue of NMe_2I .— $\text{B}\cdot\text{H}_2\text{PtCl}_6$: orange regular crystals (Lüdecke, *J.* 1880, 512; Topsøe, *J.* 1883, 618). S. (alcohol) 0362. More soluble than the di- and still more so than the mono-methylamine platinochloride (Eisenberg, *A.* 205, 139).— $\text{B}\cdot\text{H}_2\text{IrCl}_6$: reddish-brown octahedra (Vincent, *Bl.* [2] 43, 155).— $\text{B}\cdot\text{HfAuCl}_4$: yellow monoclinic crystals. V. sl. sol. water, sol. alcohol. [220°] (Hesse, *J. pr. T.* 71, 480; Zay, *G.* 13, 420).— $\text{B}\cdot\text{H}_2\text{Rh}_2\text{Cl}_4$, 9aq (Vincent, *C. R.* 101, 822).— $\text{B}\cdot\text{HfCdCl}_4$: triclinic crystals (Hjortdahl, *J.* 1882, 475).— $\text{B}\cdot\text{H}_2\text{HgCl}_4$: monoclinic crystals (T.).— $\text{B}\cdot\text{HHgCl}_4$: monoclinic crystals (T.).— $\text{B}\cdot\text{HHgCl}_4$: triclinic crystals (T.).— $\text{B}\cdot\text{HHgCl}_4$: rhombohedra (T.).— $\text{B}\cdot\text{HfCuCl}_4$, 2aq: monoclinic crystals. — $\text{B}\cdot\text{HfCdBr}_4$: six-sided hexagonal prisms.— $\text{B}\cdot\text{H}_2\text{PtBr}_6$.— $\text{B}\cdot\text{H}_2\text{I}_3\text{BiI}_4$.— $\text{B}\cdot\text{H}_2\text{I}_2\text{BiI}_4$: six-sided crimson plates (Kraut, *A.* 210, 816).— $\text{B}\cdot\text{HNO}_3$ [153°]. Long needles or prisms, v. sol. hot alcohol (Franchimont, *R. T. C.* 2, 338).— $\text{B}\cdot\text{H}_2\text{SO}_4\text{Al}_2(\text{SO}_4)_2$, 24aq. [100°]. Large crystals (Reckenschuf, *A.* 83, 343).— $\text{B}\cdot(\text{H}_2\text{O})_2(\text{V}_2\text{O}_5)$, 7aq (Bailey, *C. J.* 45, 692).— $\text{B}\cdot\text{H}_2\text{C}_2\text{O}_4$: plates (Loschmidt, *J.* 1865, 375).—Benzene sulphate [89°] (Westenhoff, *Am.* 10, 129).

Tetra-methyl-ammonium hydroxide NMe_4OH . Heat of neutralisation (by HCl) 27,900 (Müller, *A. Ch.* [6] 15, 531). Obtained by digesting NMe_4I with moist Ag_2O (Hofmann, *Tr.* 1850, 98; *C. J.* 4, 321). White crystalline deliquescent mass, v. e. sol. water. Absorbs CO_2 with avidity. Its solution is strongly alkaline and caustic. Decomposed by heat into NMe_2 and MeOH (Hofmann, *B.* 14, 491). Neutralises acids, forming the following salts.

Iodide NMe_4I . S.G. 1.827; d_4^{20} 1.831 (Clarke, *Am. S.* [3] 16, 401). The chief product of the action of MeI on ammonia and on mono-, di-, and tri-methylamine. Best obtained by heating a solution of NH_3 in methyl alcohol with MeI at 100° – 120° (Lawson a. Collie, *C. J.* 53, 624). Dimetric prisms (from water). Sl. sol. water, almost insol. alcohol, insol. ether. Decomposes at a dull red heat into NMe_2 and MeI . Unites with iodoform forming red crystals of $\text{NMe}_4\text{I}_2\text{CHI}_3$. When heated with liquefied NH_3 , in which potassium has been dissolved, the products are KI , NMe_3 , and ethane (Thompson a. Cundall, *C. J.* 53, 761). Unites with halogens, forming NMe_4I (Wielzien, *A.* 91, 41; 99, 1), NMe_4I_2 [130°], NMe_4I_3 [110°] (Geuther, *A.* 240, 68), NMe_4I_4 , NMe_4I_5 , NMe_4I_6 , $(\text{NMe}_4\text{I})_2\text{Cl}_2$ (W.), NMe_4IBr [190°] (Dobbin a. Masson, *C. J.* 49, 851), and NMe_4ICl [216° – 220°]. The compound NMe_4I is converted by ammonia into NMe_3 , NH_3 , a dark-coloured explosive body (Stahlschmidt, *P.* 119, 421).— NMe_4HgI : small light-yellow prisms, m. sol. alcohol.— $(\text{NMe}_4)_2\text{SHgI}_2$: lemon-yellow scales (Risse, *A.* 107, 223).— $(\text{NMe}_4)_2\text{BiI}_4$: amorphous scarlet pp. (Kraut, *A.* 210, 816).— $\text{NMe}_4\text{IHgCy}_2$: white crystals. On heating for a

long time at 200° it is converted into the isomeric NMe_2CyHgI (Claus a., Merck, B. 16, 2738).

Bromide NMe_2Br . S. 55-26 at 15°. Obtained by neutralising the hydroxide by HBr. Very deliquescent needles. Dissociates at 360° into NMe_2 and MeBr (Lawson a. Collie, C. J. 53, 825). Forms crystalline compounds with the halogens (Dobbin a. Masson, C. J. 49, 848).— $(\text{NMe}_2\text{Br})_2\text{PtBr}_2$: regular octahedra (Topsoë).

Chloride NMe_2Cl . H.F. 27,500 (Müller, Bl. [2] 44, 192). Deliquescent crystals. Decomposed above 360° into NMe_2 and, doubtless, MeCl (L. a. C.).— $(\text{NMe}_2\text{Cl})_2\text{HgCl}_2$: trimetric crystals (T.).— $\text{NMe}_2\text{Cl}_5\text{HgCl}_2$: rhombohedra.— $(\text{NMe}_2\text{Cl})_2\text{CuCl}_2$: trimetric crystals.— $\text{NMe}_2\text{AuCl}_2$: dimetric crystals.

Fluoride NMe_2F . From the hydroxide and HF. Radiating crystals. Decomposes at 180° into NMe_2 and MeF (L. a. C.).

Nitrate NMe_2NO_3 . S. (94 p.c. alcohol) 3 at 11°. Obtained, together with NMe_2HNO_3 , $\text{NMe}_2\text{H}_2\text{NO}_3$, and NMe_2HNO_2 , by heating methyl nitrate with NH_3 dissolved in MeOH (Duvillier a. Buisine, C. R. 90, 872). The di- and tri-methylamines are formed in very small quantity (Duvillier a. Malbot, C. R. 100, 177). Formed also by treating NMe_2I with AgNO_3 (Lawson a. Collie, C. J. 53, 628). Needles or plates, v. sol. water, sl. sol. cold alcohol. Not attacked by boiling KOH aq. Above 300° it yields NMe_2 , formic acid, MeNO_2 , and NO (L. a. C.).

Nitrite NMe_2NO_2 . From NMe_2I and AgNO_2 . Deliquescent crystals. Decomposed above 300° into NMe_2 , MeNO_2 , Me_2O , NO , and oxygen (L. a. C.).

Sulphate $(\text{NMe}_2)_2\text{SO}_4$. [280°]. Deliquescent crystals. Decomposed above 280° into NMe_2 and $\text{NMe}_2\text{SO}_4\text{Me}$, which then undergoes further decomposition (L. a. C.).

Chromates $(\text{NMe}_2)_2\text{CrO}_4$: yellow trimetric crystals, v. e. sol. water (Hjortdahl, J. 1882, 475).— $(\text{NMe}_2)_2\text{Cr}_2\text{O}_7$: orange trimetric tables, v. sol. water.

Sulphite $\text{NMe}_2\text{SO}_3\text{H}$ aq. [180°]. Decomposes above 300°, yielding NMe_2 , SO_2 , MeOH , and other products (L. a. C.).

Sulphydrate NMe_2SH . Very deliquescent. Decomposes above 200° into NMe_2 and MeSH .

Phosphate. From NMe_2I and Ag_3PO_4 . Forms a strongly alkaline solution. Decomposed at a high temperature into NMe_2 , methyl alcohol, and HPO_4 (L. a. C.).

Vanadate NMe_2VO_3 (Bailey, C. J. 45, 693).

Carbonates $\text{NMe}_2\text{CO}_2\text{H}$. H.F. 20,870 (Müller). Obtained by saturating a solution of the base with CO_2 (L. a. C.). Deliquescent crystals, decomposing above 180° into NMe_2 , methyl alcohol, and CO_2 .— $(\text{NMe}_2)_2\text{CO}_3$. H.F. 19,100. Obtained by acting on NMe_2I (2 mols.) with Ag_2CO_3 , $\frac{1}{2}\text{Ag}_2\text{O}$ (Müller, Bl. [2] 44, 191).

Oxalate $(\text{NMe}_2)_2\text{C}_2\text{O}_4$. Formed from NMe_2OH and oxalic acid, or from NMe_2I and silver oxalate. Deliquescent crystals, decomposed above 360° into NMe_2 and methyl oxalate, the latter being further resolved into Me_2O , CO , and CO_2 .

Cyanide NMe_2Cy . Prisms. Sublimes at 226°. V. sol. water, m. sol. alcohol, insol. ether and chloroform (Claus a. Merck, B. 16, 2738).— $\text{NMe}_2\text{CyHgCy}$. [275° uncor.]. Yellow crystals.— $\text{NMe}_2\text{CyAgCy}$. [212° uncor.]. From AgCy

and NMe_2I or NMe_2Cy (Thompson, B. 16, 2338). Long colourless prisms of slender needles; v. e. sol. water and alcohol, insol. ether. On dry distillation it yields NMe_2 , acetonitrile, and methyl carbamide.

Ferrocyanides $(\text{NMe}_2)_2\text{FeCy}$, 18aq. Laminar granular mass (Barth, B. 8, 1484).— $(\text{NMe}_2)_2\text{H}_2\text{FeCy}$, 2aq (E. Fischer, A. 190, 184).

Ferricyanide $(\text{NMe}_2)_2\text{FeCy}$, 3aq. From NMe_2I and silver ferricyanide (Bernheimer, B. 12, 408). Unstable hygroscopic prisms; sol. water, insol. alcohol.

Cobalticyanide $(\text{NMe}_2)_2\text{CoCy}$, 18aq. Yellow tables (C. a. M.).

Acetate NMe_2OAc . [c. 70°]. From NMe_2OH and HOAc . Deliquescent needles, decomposed at 200° into NMe_2 and MeOAc (L. a. C.).

Benzoate NMe_2OBz . [220°-230°]. Long deliquescent needles. Decomposed above 230° into NMe_2 and MeOBz (L. a. C.).

Cyanurate $\text{NMe}_2\text{OC}_2\text{N}_4(\text{OH})_2\text{aq}$ (Claus, J. pr. [2] 38, 225).

Picrate. [313°] (Lossen, A. 181, 374).

Trimethylamine iodo-methylo-iodide $\text{NMe}_2\text{I.CH}_2\text{I}$. From NMe_2 and methyleneiodide (Hofmann). Needles. Not attacked by NH_3 . Moist silver oxide gives $\text{NMe}_2(\text{OH}).\text{CH}_2\text{I}$ and $\text{Me}(\text{OH}).\text{CH}_2\text{OH}$. It yields the platinum salt $\text{PtCl}_2(\text{NMe}_2\text{Cl.CH}_2\text{I})_2$.

Trimethylamine ethylo-iodide $\text{C}_2\text{H}_5\text{NI}$ i.e. NMe_2EtI . From NMe_2 and EtI (Müller, A. 108, 1). Gives the following derivatives (Topsoë, J. 1883, 620).— $(\text{NMe}_2\text{EtCl})_2\text{HgCl}_2$: trimetric crystals.— $\text{NMe}_2\text{EtClHgCl}_2$: monoclinic crystals.— $\text{NMe}_2\text{EtCl}(\text{HgCl}_2)_2$: trimetric crystals.— $(\text{NMe}_2\text{EtCl})_2\text{CuCl}_2$: trimetric crystals.—Aurochloride $\text{NMe}_2\text{EtAuCl}_4$: dimetric crystals.— $(\text{NMe}_2\text{EtCl})_2\text{PtCl}_2$: regular crystals.—Picrate [300°] (Lossen, A. 181, 374). The ethylohydroxide is decomposed on distillation into NMe_2 , ethylene, and water. NMe_2EtCl on distillation yields MeCl , NMe_2Et , and NMe_2 .

Trimethylamine ethylo-tri-iodide NMe_2EtI_3 . [64°]. Regular crystals (Lüdecke, A. 240, 85).

Tri-methylamine ethylo-penta-iodide NMe_2EtI_5 . [26°]; dark-green tables (Geuther, A. 240, 66).

Trimethylamine ethylo-ennea-iodide

NMe_2EtI_9 . [38°]; black-green crystals.

Trimethylamine bromo-ethylo-bromide $\text{C}_2\text{H}_5\text{Br.NMe}_2\text{Br}$. From NMe_2 and ethylene bromide at 45° (Hofmann, C. R. 47, 558). Needles, v. e. sol. hot alcohol. Ammonia as well as moist Ag_2O converts it into $\text{C}_2\text{H}_5\text{NMe}_2\text{OH}$.— $(\text{C}_2\text{H}_5\text{Br.NMe}_2\text{Cl})_2\text{PtCl}_2$. Octahedral crystals.— $\text{C}_2\text{H}_5\text{Br.NMe}_2\text{I}$ (Baeyer, A. 140, 312).

Trimethylamine iodo-ethylo-iodide $\text{C}_2\text{H}_5\text{I.NMe}_2\text{I}$. From neurine, HI, and phosphorus (Baeyer, A. 140, 309; 142, 324). Crystalline, sl. sol. cold water. Moist Ag_2O yields $\text{C}_2\text{H}_5\text{NMe}_2\text{OH}$.— $(\text{C}_2\text{H}_5\text{I.NMe}_2\text{Cl})_2\text{PtCl}_2$: octahedra.

Trimethylamine allylo-bromide $\text{C}_3\text{H}_5\text{NBr}$ i.e. $\text{NMe}_2\text{C}_3\text{H}_5\text{Br}$. Forms a dibromide $\text{NMe}_2\text{C}_3\text{H}_5\text{Br}_2$ [175°] of which the gold salt melts at 148° (Partheil, B. 22, 8317).

Trimethylamine bromo-allylo-bromide $\text{NMe}_2\text{Br.C}_3\text{H}_5\text{Br}$ [165°]. Formed from $\text{NMe}_2\text{C}_3\text{H}_5\text{Br}$ and alcoholic KOH . Colourless prisms, v. sol. water and alcohol, insol. ether,

gives a perbromide $\text{NMe}_2\text{Br} \cdot \text{CH}_2\text{CHBr} \cdot \text{CHBr}_2$ crystallising in scales [156°].—Platinochloride $(\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{Cl})_2\text{PtCl}_4$. [220°].—Aurochloride $\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{AuCl}_2$. [181°].

Trimethylamine¹ propylo-iodide NMe_2PrI . [190°] (Langeli, *G.* 16, 385).

Trimethylamine iodo-propylo-iodide $\text{NMe}_2\text{I} \cdot \text{C}_3\text{H}_7\text{I}$. [151°]. From the allylo-iodide and HI at 100° (Partheil, *B.* 22, 3320). Colourless needles, sol. water and alcohol, insol. ether. Alcoholic KOH regenerates the allylo-compound.— $(\text{C}_2\text{H}_5\text{I} \cdot \text{NMe}_2\text{Cl})_2\text{PtCl}_4$. [237°].—Aurochloride $(\text{C}_2\text{H}_5\text{I} \cdot \text{NMe}_2\text{Cl})\text{AuCl}_2$. [135°].

Trimethylamine trimethenyl bromide $\text{NMe}_2\text{Br} \cdot \text{CH} \begin{smallmatrix} \text{CH} \\ \parallel \\ \text{CH} \end{smallmatrix}$. From the bromo-allylo-bromide and alcoholic KOH.—Aurochloride $(\text{NMe}_2\text{Cl} \cdot \text{C}_2\text{H}_3\text{AuCl})_2$.

Dibromide $\text{NMe}_2\text{Br} \cdot \text{CH} \begin{smallmatrix} \text{CHBr} \\ \parallel \\ \text{CHBr} \end{smallmatrix}$. [187°].

From the preceding and Br. Colourless, somewhat hygroscopic crystals. Forms a platinochloride [232°] and an aurochloride [193°] both crystallising in tables.

Trimethylamine bromo-pentenyl bromide $\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{Br}$. Formed from trimethylamine and di-bromo-amylene (valerylene bromide) (Ladenburg, *B.* 14, 231, 1342). With HI it forms $\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{I}$. Silver chloride forms $\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{Cl}$, whence $(\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{Cl})_2\text{PtCl}_4$ and $\text{C}_2\text{H}_5\text{Br} \cdot \text{NMe}_2\text{Cl} \cdot \text{AuCl}_2$, both crystalline.

Trimethylamine isoamyl-triiodide $\text{NMe}_2\text{C}_5\text{H}_{11}\text{I}_3$. [80°]. From NMe_2 and $\text{C}_5\text{H}_{11}\text{I}$, the product being treated with iodine. Dark-brown prisms, nearly insol. water, v. sol. alcohol.

TRIMETHYLAMMELIDE v. vol. ii. p. 325.

DI-METHYL-AMMELINE v. vol. ii. p. 321.

METHYL-AMYL-ACETAL v. ALDEHYDE.

METHYL-ISOAMYL-ANILINE $\text{C}_{12}\text{H}_{15}\text{N}$ i.e. $\text{C}_5\text{H}_7\text{NMe} \cdot \text{C}_6\text{H}_5$. (257°). S.G. 22 906. Obtained together with $\text{C}_5\text{H}_7\text{OH}$ and water by distilling $\text{C}_5\text{H}_7\text{NMeEt} \cdot \text{C}_6\text{H}_5\text{OH}$ (Hofmann, *A.* 79, 15). Formed also by heating dimethylaniline with isoamyl bromide (Claus a. Rautenborg, *B.* 14, 622).— $\text{B}^1 \cdot \text{H} \cdot \text{PtCl}_4$: crystalline pp.— $(\text{B}^1\text{H})_2\text{BiI}_3$.

METHYL-AMYL-ARSINE v. Organic compounds of ARSENIC.

METHYL-AMYL-BENZENE v. AMYL-TOLUENE.

Di-methyl-isoamyl-benzene v. AMYL-XYLENE.

METHYL-ISOAMYL-BENZENE SULPHONIC ACID $\text{CH}_3 \cdot \text{C}_5\text{H}_7 \cdot (\text{C}_6\text{H}_4)_2 \cdot \text{SO}_3\text{H}$. From γ -isoamyl toluene by sulphonation (Fittig a. Bigot, *A.* 141, 166).— KA' . The Ba salt is a deliquescent gummy mass.

Di-methyl-isoamyl-benzene sulphonic acid $(\text{CH}_3)_2\text{C}_5\text{H}_7 \cdot (\text{C}_6\text{H}_4)_2 \cdot \text{SO}_3\text{H}$. Formed by sulphonating isoamyl-xylene (F. a. B.). The K and Ba salts were not obtained in crystals.

METHYL-AMYL-CARBINOL v. HEPTYL-ALCOHOL.

DI-METHYL AMYLENE DIKETONE

$\text{C}_8\text{H}_{16}\text{O}_2$ i.e. $\text{CH}_3 \cdot (\text{CO} \cdot \text{CH}_2)_2 \cdot \text{Di-ethyl-acetyl-acetone}$. (a. 203°). From $(\text{CH}_3 \cdot \text{CO})_2\text{C} \cdot \text{EtNa}$ and EtI at 180° (Combes, *A. Ch.* [6] 12, 250). Liquid. Split up by KOH into $\text{CH}_3 \cdot \text{CO}_2\text{K}$ and $\text{CH}_3 \cdot \text{CO} \cdot \text{CH} \cdot \text{Et}$.

Di-methyl amylene diketone $\text{C}_8\text{H}_{16}\text{O}_2$ i.e. $(\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2)_2$. Di-acetyl-pentane.

[49°]. (212°–215° at 800 mm.). From the carboxylic ether and a dilute solution of KOH in MeOH (Kipping a. Peckin, *C. J.* 55, 337). V. sol. cold ether, alcohol, acetone, chloroform, and light petroleum. Cold conc. HNO_3 dissolves it without decomposition. Conc. H_2SO_4 forms a colourless oil $\text{C}_8\text{H}_{16}\text{O}$.

Dioxim $(\text{CH}_3 \cdot \text{C}(\text{NOH}) \cdot \text{CH}_2 \cdot \text{CH}_2)_2$. [85°]. Colourless moss-like crystals; v. sol. cold water.

DI-METHYL-AMYLENE-DIKETONE CARBOXYLIC ACID

$\text{CO}_2\text{H} \cdot \text{CHAc} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CH}_3$. From its ether and KOH dissolved in MeOH. Liquid, miscible with water. Decomposed by heat into CO_2 and the diketone.

Ethyl ether EtA'. (240° at 200 mm.). Prepared from sodium aceto-acetic ether and $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Br}$ (Kipping a. Perkin, *C. J.* 55, 333). Thick oil. Alcoholic NH_3 converts it into $\text{Ac} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{C} \begin{smallmatrix} \text{CMe} \\ \diagup \\ \text{CO} \end{smallmatrix} \text{NH}$

[c. 235°], which forms monoclinic crystals; $a:b:c = 7.487:1:3.997$; $\beta = 79^\circ 11'$. This 'dehydro-amide' yields an acetyl derivative $\text{C}_{10}\text{H}_{17}\text{AcNO}_2$, an oil, converted by boiling water into the amide $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}(\text{COMe}) \cdot \text{CONH}_2$, which melts between 200° and 228°.

METHYL AMYL ETHER v. METHYL AMYL OXIDE.

METHYL AMYL KETONE $\text{C}_8\text{H}_{16}\text{O}$ i.e. $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_3$. (151°). S.G. 2 837. Formed by oxidising *sec*-heptyl alcohol obtained from *n*-heptane (Schorlemmer, *A.* 161, 279; 217, 149). Fragrant liquid. Unites with NaHSO_4 . Yields on oxidation acetic and *n*-valeric acids. Formed also by dissolving heptinene C_5H_9 in conc. H_2SO_4 and distilling the product with water (Behal, *A. Ch.* [6] 15, 270).

Methyl isoamyl ketone $\text{C}_8\text{H}_{16}\text{O}$ i.e. $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}(\text{CH}_3)_2$. (144°). S.G. 2 828; $d_{20}^{20} = 0.818$ (Rohn, *A.* 190, 308); $d_{20}^{20} = 0.821$ (Wagner, *J. R.* 16, 705).

Formation.—1. By heating a mixture of calcium hexoate with calcium acetate (Schmidt, *B.* 5, 604).—2. By the action of zinc isoamyl on acetyl chloride (Popoff, *A.* 145, 283).—3. By oxidising the corresponding heptyl alcohol (Grimshaw, *A.* 166, 169).—4. By boiling isobutyl-aceto-acetic acid with aqueous KOH: the yield being 70 p.c. (Purdie, *C. J.* 89, 467).

Properties.—Oil. Reduced by sodium to *sec*-heptyl alcohol and di-isopropyl-pinacone. CrO_3 oxidises it to acetic, isovaleric, and isohexanoic acids. It combines with NaHSO_4 .

Methyl amyl ketone $\text{Me} \cdot \text{CO} \cdot \text{CHMePr}$. (142°–147°). From methyl-propyl-aceto-acetic ether (E. J. Jones, *A.* 226, 293). Oil, smelling of pepper-mint.

Methyl amyl ketone $\text{CH}_3 \cdot \text{CO} \cdot \text{CHMePr}$. (135°). S.G. 22 815. One of the products of the saponification of methyl-isopropyl-aceto-acetic ether (Van Romburgh, *R. T. C.* 5, 235). Does not combine with NaHSO_4 . Does not give a solid phenyl-hydrazide.

Methyl amyl ketone $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CMe}_2$. (125°–130°). Obtained by oxidising the alcohol $\text{CMe}_2 \cdot \text{CH}_2 \cdot \text{CMe}_2 \cdot \text{OH}$ (Butlerow, *A.* 189, 78). Oxidised by CrO_3 to acetic acid and $\text{CMe}_2 \cdot \text{CO}_2\text{H}$. Does not combine with NaHSO_4 .

Methyl amyl ketone $\text{CH}_3 \cdot \text{CO} \cdot \text{CHEt}_2$. (138°). S.G. 22 817. Obtained by boiling di-ethyl-aceto-

acetic ether with baryta-water (Frankland & Dupps, *A.* 193, 212). Forms an oily compound with NaHSO_4 .

Methyl amyl ketone $\text{CH}_3\text{CO.CMe.Et}$. *Methyl-amyl-pinacol.* (132°). S.G. 2.812; d_4^{25} 0.825. Obtained by the action of ZnMe_2 on CMe.Et.COCl (Wyschnegradsky, *A.* 178, 103). CrO_3 oxidises it to HOAc and CMe.Et.CO.H .

Methyl amyl ketone $\text{CH}_3\text{CO.C}_4\text{H}_9$. (142°–146°). From *sec*-heptyl alcohol derived from petroleum heptane (90°). Gives acetic acid on oxidation (Schorlemmer, *A.* 166, 172).

Methyl isoamyl diketone $\text{CH}_3\text{CO.CO.C}_4\text{H}_9$. *Methyl-isoamyl-glyoxal* (163°). S.G. d_4^{25} 0.814. From methyl nitrosohexyl ketone (Otto & Pechmann, *B.* 22, 2123). Oil, solidified by cold.

Phenyl-hydrasid. [100°]. White needles (from benzene-ligroin).

Di-phenyl-di-hydrasid. [114°]. Needles (from dilute alcohol).

D β -oxim. [173°]. Needles.

Oxim-phenyl-hydrasid. [132°]. White needles (from benzene-ligroin).

METHYL AMYL KETONE CARBOXYLIC ACID $\text{CH}_3\text{CO.CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$. [30°]. A product of the action of a boiling solution of KOH in MeOH upon dimethyl-amylene diketone carboxylic ether (Kipping & Perkin, jun., *C. J.* 55, 398). Also from sodium-malonio ether and $\text{CH}_3\text{CO.CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$, the resulting dicarboxylic acid being distilled. Crystalline plates, v. sol. water.— Ag^+ : colourless plates.

METHYL ISO-AMYL OXIDE $\text{C}_7\text{H}_{14}\text{O}$ *i.e.* $\text{CH}_3\text{O.C}_4\text{H}_9$. Mol. w. 102. (92°). V.D. 3.74. S.V. 148-1 (Schiff). From MeONa and isoamyl iodide (Williamson, *C. J.* 4, 233).

METHYL-AMYL-PIPERIDINE $\text{C}_{11}\text{H}_{23}\text{N}$ *i.e.* $\text{C}_4\text{H}_9\text{N}(\text{C}_2\text{H}_5)(\text{CH}_2)$. (190°–193°). Prepared by dry-distillation of the alkaline hydrate obtained by the action of moist Ag_2O on amyl-piperidine methylo-iodide (Schotten, *B.* 15, 422). Colourless fluid. Sl. sol. water. With MeI it forms a crystalline methylo-iodide.— B^+HCl : hygroscopic salt.—(B^+HCl) $_2\text{PtCl}_4$: sparingly soluble pp., melts at [140°].

METHYL AMYL SULPHIDE $\text{CH}_3\text{S.C}_4\text{H}_9$. (137°). V.D. 58-6. From NaSC_4H_9 and MeI (Obermeyer, *B.* 20, 2924).

METHYL AMYL DI-THIO-CARBONATE $\text{CO(SMe)(SC}_4\text{H}_9)$. (c. 140°). From $\text{Cl.CO.SC}_4\text{H}_9$ and NaSMe (Schöne, *J. pr.* [2] 32, 244). Liquid, smelling like CS_2 . With ammonia it gives HSC_4H_9 , urea, and HSMe . Alcoholic potash forms K_2CO_3 , methyl mercaptan, and HSC_4H_9 .

METHYL-ANHYDRO-ACETONE-BENZIL *v.* vol. i. p. 463.

METHYL-ANILINE $\text{C}_7\text{H}_7\text{NHMe}$. Mol. w. 107. (193° uncor.) (Friswell & Green, *B.* 19, 2035). S.G. d_4^{25} 0.978. H.F. –5600. H.C.v. 973,000 (Petit, *C. R.* 107, 266). Heat of neutralisation (by HCl) 6,910 (Vignon, *C. R.* 106, 1722).

Formation.—1. Together with dimethylaniline from aniline and MeI or MeBr (Hofmann, *A.* 74, 150; *B.* 10, 591; cf. Kern, *B.* 10, 195).—2. Together with dimethylaniline by heating methyl alcohol with aniline and HCl at 200° under pressure (Girard, *Bl.* [2] 24, 120; cf. Poirrier & Chappat, *J.* 1866, 903).—3. By heating aniline hydrobromide (or hydroiodide) with 10 p.c. more than the calculated quantity of methyl

alcohol to 150° for 8 hours; the yield is 34 p.c. of the theoretical (Reinhardt & Staedel, *B.* 16, 29; cf. Krämer & Grodzky, *B.* 13, 1008).—4. By heating acetanilide with alcoholic sodium ethylate at 170°–200° under pressure (Seifert, *B.* 13, 1355).—5. By adding sodium to a solution of acetanilide in xylene, treating the resulting sodium-acetanilide with MeI and boiling the product ($\text{C}_6\text{H}_5\text{NMeAc}$) with alcoholic potash (Hepp, *B.* 10, 327).—6. From its formyl derivative (Pictet & Crépieux, *B.* 21, 1108).—7. By boiling diazobenzene-methyl-anilide (100 g.) with conc. HCl (200 c.c.), making alkaline with NaOH , and distilling with steam; yield 40 g. (Friswell & Green, *B.* 19, 2035).

Purification.—By the action of MeOH and HCl on aniline a mixture of bases is obtained. On adding dilute H_2SO_4 , aniline sulphate separates, and the bases liberated from the filtrate may then be heated with AcCl . On pouring the product into water the acetyl derivative of methyl-aniline separates in long needles, while dimethyl-aniline hydrochloride remains in solution. The acetyl derivative may be quickly saponified by boiling with conc. HClAq (Hofmann, *B.* 7, 523). The mixture of bases may also be treated with nitrous acid, whereby a diazo-benzene salt, phenyl-methyl-nitrosamine, and nitroso-dimethylaniline are formed. The nitrosamine, being insoluble in water and acids, separates as a yellow oil, and may be reconverted by tin and HCl into methyl-aniline (Noelting & Boasson, *Bl.* [2] 28, 2).

Properties.—Oil. Its aqueous solution is not coloured by bleaching-powder. With NaOBr it gives a yellow pp. (Denigès, *C. R.* 107, 662). With CuSO_4 it forms a compound $\text{B' (CuSO}_4)_4\text{CuO}$ (Lachovitch, *M.* 9, 514).

Estimation.—1. It is treated with a mixture of Ac_2O (1 vol.) and di-methyl-aniline (10 vols.), water is added after the reaction, and the solution titrated with phenol-phthalein. The dimethyl-aniline does not interfere with the reaction, and the mixture of it with the acetic anhydride keeps well (Girard, *Bl.* [3] 2, 142).—2. In a mixture of aniline, methyl-aniline, and dimethyl-aniline the aniline is first determined by diazotisation and ppn. by (8)-naphthol disulphonic acid (*R.*) and NaCl . Another portion of the mixed bases (2 g.) is mixed with Ac_2O (4 g.), and, after 30 minutes water (50 c.c.) is added. The liquid is boiled to decompose the excess of Ac_2O , and the acid solution titrated with Na_2CO_3 using phenol-phthalein as indicator. The amount of Ac_2O found plus that required by the aniline previously determined is then subtracted from the amount taken, and gives a measure of the methyl-aniline present (Reverdin & De la Harpe, *B.* 22, 1004).—3. In a mixture of mono- and di-methyl-aniline the amount of the former present may be known by observing the rise of temperature on mixing with an equal volume of Ac_2O .

Reactions.—1. HNO_3 gives off red fumes containing CO_2 , and forms tetra-nitro-methyl-aniline (Van Romburgh, *R. T. C.* 2, 81).—2. NaN_3 added to a solution of its hydrochloride forms phenyl-methyl-nitrosamine $\text{C}_6\text{H}_5\text{NMe.NO}$, a yellow oil solidifying when cooled as needles [12°–15°]. It gives no reaction with gallic acid (Reverdin & De la Harpe, *B.* 22, 1006).—3. Boiling sulphur forms methenyl-amido-phenyl mercap-

tan and crystalline C_6H_5NS , [89°] (860°) (Möhlau a. Krohn, *B.* 21, 59).—4. A solution of methyl-aniline sulphate saturated with SO_2 forms with an aqueous solution of alloxan small yellowish prisms of $CO \begin{smallmatrix} NH \\ \diagup \quad \diagdown \\ CO \end{smallmatrix} C(OH).SO_2NHPhMe$ 2aq (Pellizzari, *A.* 248, 148).—5. An aqueous solution of alloxan forms $(C_6H_5N_2O_2)(NHPhMe)$, a compound crystallising in white scales, with a hydrochloride crystallising in prisms.—6. *Diazobenzene chloride* and aqueous $NaOAc$ form $PhNMe.N:NPh$, a yellowish oil, decomposed by dilute H_2SO_4 into diazobenzene sulphate (or phenol) and methyl-aniline, and by $SnCl_2$ and HCl into phenyl-hydrazine and methyl-aniline (Nölting a. Binder, *B.* 20, 3017).—7. *p-Nitro-diazobenzene chloride* and $NaOAc$ form $C_6H_4(NO_2).N:N.O_2H.NHMe$ crystallising in red needles [134°], v. sol. hot alcohol (N. a. B.).—8. *Bromo-acetophenone* forms $C_6H_4.CO.CH_2.NPhMe$ in the cold, and on boiling it gives phenyl-indole and phenyl-methyl-indole (Cullmann, *B.* 21, 2595).

Salts.— $B'H_2PtCl_4$. Yellow scales. Decomposed by boiling water (De Coninck, *Bl.* [2] 45, 181).— $B'HCO_2Br$. Trimetric crystals (Hjortdahl, *J.* 1882, 522).— $B'H_2SnBr_2$. Monoclinic crystals. — $B'HSO_4Me$. Needles (Clacsson a. Lundvall, *B.* 13, 1703).

Formyl derivative $C_6H_5.NMeCHO$. [12.5°] (N. a. L.). (250°) (N. a. L.); (256°) (Pictet a. Crépiaux, *B.* 21, 1108). S.G. $\frac{1}{2}$ 1.097. From sodium formanilide and MeI (Norton a. Livermore, *B.* 20, 2273). Formed also from methyl-aniline and the hydrochloride of formimido-ether (Pinner, *B.* 16, 1652). Oil; could not be solidified by Pictet. When boiled with 12½ p.c. nitric acid it yields dinitromethyl-aniline.

Acetyl derivative $C_6H_5.NMeAc$. '*Ex-algine*'. [101.5°] (Kamensky, *A.* 214, 236). (256°) (P. a. C.). Formed from sodium-acet-anilide and MeI (Hepp, *B.* 10, 328; Hofmann, *B.* 10, 599). Formed also by the action of acetyl bromide on dimethyl-aniline (Staedel, *B.* 19, 1947). White needles and tablets, sl. sol. cold water, v. sol. dilute alcohol. As a medicine it has an energetic action on the cerebro-spinal system (Dujardin-Beaumetz, *C. R.* 108, 571; cf. Giraud, *C. R.* 108, 749). It is a good antiseptic. Boiling nitric acid forms (4, 2, 1)-di-nitro-methyl-aniline.

Thio-acetyl derivative $CH_3CS.NPhMe$. [59°]. (290°). From the acetyl derivative and sulphide of phosphorus (Wallach, *B.* 13, 518). Monoclinic plates (from $CHCl_3$). Insol. water and alkalis, sol. alcohol and ether.

Propionyl derivative $CH_3CH_2.CO.NPhMe$. [58.5°]. From sodium propionanilide and MeI (Norton a. Allen, *B.* 18, 1998). With boiling HNO_3 (100 pts. of S.G. 1.029) it yields (4, 2, 1)-di-nitro-methyl-aniline.

Oxalyl derivative $(CO.NPhMe)_2$. (250°). Forms oxalic acid, alcohol, and methyl-aniline (Norton a. Livermore, *B.* 20, 2273). Boiling nitric acid converts it into di-nitro-methyl-aniline [177°].

Benzoyl derivative $C_6H_5.NMeBz$. [63°]. From methyl-aniline and $BzCl$ (Hepp, *B.* 10, 329). Formed also by heating di-methyl-aniline with benzoyl chloride at 180° (Hess, *B.* 18, 685). Large monoclinic crystals; insol. water, but v.

sol. other solvents. Gives a mono-nitro-derivative [186°].

Nitrosamine $PhMeN.NO$. [12°–15°]. From methyl-aniline hydrochloride and aqueous $NaNO_2$ (Hepp, *B.* 10, 329; Fischer, *A.* 190, 151; Reverdin a. De la Harpe, *B.* 22, 1006). Yellow oil, solidified by cold. Reduced by tjn and HCl to methyl-aniline. Gaseous HCl passed into its solution in alcohol-ether forms the isomeric [4:1] $NO.C_6H_4.NHMe$ [118°] which crystallises from water in prisms, v. sol. alcohol, and is converted by heating with aqueous $NaOH$ into *p*-nitrosophenol and methylamine (Fischer a. Hepp, *B.* 19, 2991).

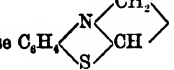

Di-methyl-aniline $C_6H_4.NMe_2$. Mol. w. 121. [2°–2.5°] (Friewall a. Green, *private communication*). (193°). S.G. $\frac{20}{4}$.9575. $\mu_D = 1.559$ (Brühl, *A.* 235, 14). S.H. (9°–82°) .448 (Schiff, *G.* 17, 286). Heat of neutralisation (by HCl) 6,810 (Vignon, *C. R.* 106, 1722). Formed by heating aniline with MeI or $MeCl$.

Preparation.—1. Aniline hydrobromide (or hydroiodide) is heated with (2 mols. + 10 p.c. excess of) methyl alcohol to 150° for 8 hours; the yield is 95 p.c. of the theoretical (Reinhardt a. Staedel, *B.* 16, 29; cf. Lauth, *Bl.* 7, 448).—2. Aniline (18 pts.) saturated with HCl is mixed with a further quantity (75 pts.) of aniline and methyl alcohol (75 pts.). The mixture is heated at 230° in closed vessels until the internal pressure falls. The use of a comparatively small quantity of HCl avoids the formation of toluidine and allows of the use of iron vessels. The HCl is sometimes replaced by H_2SO_4 (Schoop, *Chem. Zeit.* 11, 253).

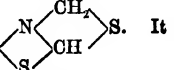

Purification.—Dimethyl-aniline can be separated from methyl-aniline by the methods described under methyl-aniline. It can also be purified by freezing (Hübner, *A.* 224, 347).

Reactions.—1. When its vapour is passed through a red-hot tube it forms benzonitrile (25 p.c.), carbazole, NH_3 , benzene, and HCy (Nietzki, *B.* 10, 474).—2. When heated in a current of HCl at 180° the products are $MeCl$ and aniline (Lauth, *B.* 6, 677).—3. With sodium hypobromite it gives a greenish-yellow pp. in the cold and a red pp. on heating (Denigès, *C. R.* 107, 662).—4. *Bromine* (1 mol.) at 115° forms methyl-violet and naphthalene (Brunner a. Brandenburg, *B.* 11, 697).—5. By nitration with a mixture of equal volumes of ordinary conc. HNO_3 and water at 0° di-nitro-di-methyl-aniline $C_6H_4(NO_2)_2.NMe_2$ [4:2:1] is formed (yield 116 p.c.). If the mixture is allowed to get warm another di-nitro-di-methyl-aniline [probably 5:3:1] is formed (yield 15 p.c.). By further nitration of the first isomeride by boiling it with fuming nitric acid tri-nitro-phenyl-methyl-nitramide $C_6H_3(NO_2)_3.NMe(NO_2)$ [6:4:2:1] is produced. By the same treatment the second isomeride is converted into di-nitro-phenyl-methyl-nitramide $C_6H_4(NO_2)_2.NMe(NO_2)$ [5:3:1?] (Mertens, *B.* 19, 2123; cf. Romburgh, *R. T. C.* 2, 81). When nitrated in presence of a large excess of H_2SO_4 (20 pts.) it yields as chief product the *m*-nitro-derivative whilst the *p*-nitro-derivative is formed in smaller quantity (Groll, *B.* 19, 198; Nölting, *B.* 19, 545).—6. Combines with aluminium chloride with great evolution of heat forming long prisms [88°] (H. Giraud, *Bl.* [8] 1, 691).

Heated in sealed tube with 5 pts. of aluminium chloride for 10 hours at 250° no change is effected. Heated in air with excess of aluminium chloride it yields a tetra-methyl benzidine $(CH_3)_4NC_6H_4C_6H_4N(CH_3)_4$, small needles [195°]. This base is split at 180° by action of HCl gas into methyl chloride and benzidine [118°].—7. Nitric oxide passed for 12 days into a solution of dimethylaniline (500 g.) in absolute alcohol (510 g.) forms $NMe_2C_6H_4N:N.C_6H_4.NMe_2$. After 3 or 4 weeks' passage of the gas there are formed a base $C_{16}H_{12}N_2$ [173°] and a violet colouring matter $C_{16}H_{12}N_2O$ (?) (Lippmann a. Lange, B. 13, 2136). 8. Nitrous acid forms nitroso-di-methyl-aniline (q. v.).—9. By heating with sulphur there is formed a compound C_6H_7NS , which is converted

by HNO_3 into a base C_6H_7N  of which

the nitrate $B'HNO_3$ crystallises in colourless needles and the platinochloride $B'H_2PtCl_6$ in plates (Mühlau a. Krohn, B. 21, 65). The compound C_6H_7NS is neither acid nor basic and

appears to be C_6H_7N . It melts at

89° and forms prisms, insol. water, and volatile with steam. On heating with sulphur it is converted into methenyl-amido-phenyl mercaptan. 10. Chloride of sulphur forms tetra-methyl-di-amido-di-phenyl disulphide $S_2(C_6H_4NMe_2)_2$ (Hannimann, B. 10, 403).—11. Heated with persulphocyanic acid it gives $S(C_6H_4NMe_2)_2$, with simultaneous formation of thiocyanic acid, CS_2 , H_2S , and NH_3 (Tursini, B. 17, 586).—12. Mixed with CS_2 and then treated with zinc-dust and HCl it gives tetra-methyl-di-amido-di-phenyl-methane [90°] and thioformic paraldehyde [212°] (Wiernik, B. 21, 3204).—13. Oxidising agents give rise to penta-methyl-tri-amido-tri-phenyl-carbinol (methyl violet) (O. a. E. Fischer, B. 11, 2099).—14. $COCl_2$ forms $CO(C_6H_4NMe_2)_2$ and, at 120°, $NMe_2C_6H_4(CO.C_6H_4NMe_2)_2$.—15. CCl_4 gives at 180°C. $(C_6H_4NMe_2)_4$ (Hannimann, B. 10, 1689). 16. Chloroform at 230° yields $CH(C_6H_4NMe_2)_3$ (Hannimann, B. 10, 1235).—17. Chloral hydrate in presence of $ZnCl_2$ forms $CCl_3.CH(OH).C_6H_4NMe_2$ (Knöfler a. Boessneck, B. 20, 3195).—18. Furfuraldehyde in presence of zinc chloride yields $C_6H_5O.CH(C_6H_4NMe_2)_2$, which crystallises in pale-yellow needles [83°] and is a strong base (O. Fischer, A. 206, 141).—19. With heptioic aldehyde and $ZnCl_2$ it also forms a condensation-product (Auger, Bl. [2] 47, 42).—20. Benzoic aldehyde and $ZnCl_2$ forms $C_6H_5.CH(C_6H_4NMe_2)_2$ (O. Fischer, B. 10, 1624).—21. When treated in the cold with acetyl bromide it becomes hot and yields acetyl-mono-methyl-aniline (Staedel, B. 19, 1947).—22. Heptoyl chloride in presence of $ZnCl_2$ forms a base [72.5°] (278° at 15 mm.) (Kraft, B. 19, 2987).—23. By heating with benzoyl chloride at 190°, benzoyl-methyl-aniline is formed with splitting off of $MeCl$ (Hess, B. 18, 685; cf. Michler, B. 9, 1899).—24. Benzoic acid (1 mol.) and P_2O_5 at 200° forms di-methyl-amido-benzophenone [38°] (O. Fischer, A. 206, 88).—25. Phthalic anhydride in presence of $ZnCl_2$ forms di-methyl-aniline phthalein.—26. Fero-trichloride forms 'malachite green'

$(NMe_2.C_6H_4)_2.CCl_3.C_6H_5$. The same body is formed by the action of Bz_2O or $BzCl$ in presence of P_2O_5 .—27. Orthoformic ether and $ZnCl_2$ form $CH(C_6H_4NMe_2)_3$.—28. Vanillin and $ZnCl_2$ form $C_{12}H_{12}N_2O_2$ [136°] (Fischer a. Schmidt, B. 17, 1895).—29. A blue compound is obtained by the oxidation of dimethylaniline with chloranil or other chlorinated quinone. It appears to have the same constitution whichever chloroquinone is used, as on reduction it always gives a leuco-base of the formula $C_{16}H_{12}N_2$ and melting-point [173°]. The latter forms glistening plates, sl. sol. cold alcohol, v. sol. hot alcohol, benzene, and ether. It forms the salts: $B'H_2Cl_2$: colourless crystals. $B'H_2Cl.PtCl_6$: fine needles. $B'Me.Cl_2$: crystals, sol. water, sl. sol. alcohol; with wet Ag_2O it gives an alkaline fluid (Meister, Lucius, a. Brüning, B. 13, 212, 2100; Wichelhaus, B. 14, 1952).—30. Acetone saturated with SO_2 forms $(C_6H_5O)(SO_2)(NMe_2Ph)$ crystallising in lustrous plates, v. sol. water and alcohol, insol. acetone (Boessneck, B. 21, 1906). Acetone and $ZnCl_2$ at 150° forms $CMe_2(C_6H_4NMe_2)_2$ [83°] (Doebner, B. 12, 810).—31. Di-methylaniline dissolved in a saturated solution of SO_2 and mixed with an aqueous solution of alloxan forms $(C_6H_4NMe_2)(NMe_2Ph)H_2SO_4$ 4aq crystallising in monoclinic plates; $a:b:c = 1.3309:1.3304$; $\beta = 93^\circ 23'$ (Pellizzari, A. 248, 148; G. 18, 329).—32. A saturated aqueous solution of alloxan forms a compound $C_{12}H_{12}N_2O_4$ aq crystallising in colourless needles, sl. sol. water, decomposing at 250° (Pellizzari, G. 17, 409). The compound forms a crystalline hydrochloride, nitrate, and oxalate, and yields a silver salt $C_{12}H_{12}AgN_2O_4$. It is decomposed by alkalis forming a compound $C_{11}H_{12}N_2O_3$, decomposing at 281°.—33. s-Trinitrobenzene forms a compound $NMe_2Ph.C_6H_3(NO_2)_3$ [108°] which crystallises in long dark violet needles, sl. sol. alcohol (Hepp, A. 215, 358).—34. Tri-nitro-toluene forms a corresponding body (H.).—35. Tri-nitro-aniline forms $NMe_2Ph.C_6H_3(NO_2)_3(NH_2)$ [141°] (Hepp).

Salts.—Dimethylaniline is apparently less basic than aniline, for if a mixture of the bases is treated with an insufficient quantity of cold aqueous HCl the base left uncombined is chiefly dimethylaniline (Morley, C. J. 51, 580).— $B'H_2SO_4$ [80°]. Sol. water, insol. ether and benzene. H.F. 8400. The normal sulphate could not be formed. At 190° the acid sulphate splits up into CO_2 and the sulphonic acid (Vignon, C. R. 107, 263).— $B'H_2HgCl_4$ [149°]. Large tables or prisms; sol. hot water and hot alcohol. Prepared by adding aqueous $HgCl_2$ to an alcoholic solution of dimethylaniline (Klein, B. 11, 1741).— $B'H_2HgOCl_2$. Formed together with the preceding. Small needles or glistening leaflets; m. sol. hot water and hot alcohol, insol. cold water, v. sol. benzene. On heating to 100° a blue colouring matter is formed.— $B'H_2HgCl_2$ (Leeds, J. 1882, 504).— $B'H_2SnCl_4$. Large monoclinic crystals (Hjortdahl, J. 1882, 523).— $B'H_2PtCl_6$. Tables.— $B'H_2PtCl_2$ 2aq (Reinhardt a. Staedel, B. 16, 29).— $B'H_2PtBr_2$. Brownish-red monoclinic needles.— $BiI_2.B'H$ (Kraut, A. 210, 824).— $(BiI_2)_2.B'H$.— $(BiI_2)_2.B'H$.— $(BiI_2)_2.B'H$.— $BiI_2.B'H$.— $B'H_2FeCy_4$. Laminæ; sl. sol. cold water, being less soluble than the methylaniline

and aniline ferrocyanides (Fischer, *A.* 190, 184).— $B_2H_2FeCy_2$ 2aq (Eisenberg, *A.* 205, 286).

Methylo-iodide $C_9H_7NMe_2I$. *Phenyl-trimethyl-ammonium iodide*. S. (alcohol) 2:2 at 8°. The combination of $PhNMe_2$ and MeI takes place rapidly (Lauth, *Bl.* 7, 448). It may also be obtained by shaking a mixture of aniline (1 mol.) with MeI (3 mols.) and KOH (2 mols.) dissolved in water (Pawlinoff, *J. R.* 13, 448; *Bl.* [2] 37, 493). Plates (from alcohol). Converted by moist Ag_2O into $C_9H_7NMe_2OH$ a deliquescent, crystalline, caustic base. When the methylo-iodide is distilled it splits up into NMe_2Ph and MeI , but these recombine in the receiver. If, however, a current of HCl be passed through the retort NMe_2PhHCl condenses in the receiver, while MeI escapes and may be condensed in a second colder receiver (Merill, *J. pr.* [2] 17, 286). When treated in a sealed tube with a solution of potassium in anhydrous liquefied ammonia it yields KI , NMe_3 , and possibly benzene (Thompson a. Cundall, *C. J.* 53, 761). Boiling conc. $KOHAq$ slowly decomposes $PhNMe_2I$ into dimethylaniline, KI , and $MeOH$ (Claus a. Rautenberg, *B.* 14, 621). The methylo-iodide gives rise to the following derivatives:— $PhNMe_2I_3$. [115°]. Brown trimetric plates (Geuther, *A.* 240, 69).— $PhNMe_2I_2$. [87°] (Dafert, *M.* 4, 500). Lustrous green monoclinic needles; $a:b:c = 1.794:1.1:2.51$; $\beta = 69^\circ 43'$.— $PhNMe_2I$. [65°]. Violet-black plates.— $PhNMe_2IZnI_2$. Trimetric crystals (Hjortdahl).— $PhNMe_2ClH_2Cl_2$. [188°]. S. 36 at 6.2°. Needles (Hübner, *A.* 224, 352).— $(PhNMe_2Cl)_2PtCl_4$. Orange needles (from water). S. 33 at 7.4°.— $(PhNMe_2)_2Cr_2O_7$. Prisms. S. 5.— $(PhNMe_2)_2Cr_2O_{10}$. Monoclinic crystals (Hjortdahl).

Ethylo-iodide B^*EtI . [125°]. Identical with methyl-ethyl-aniline-methylo-iodide; KOH splits off dimethylaniline (Claus a. Howitz, *B.* 17, 1325).— $PhNMe_2EtI_3$. [81°]. Dark-violet hexagonal rhombohedra (Geuther).— $PhNMe_2EtI_2$. [50°]. Lustrous bluish-green plates.— $PhNMe_2EtI$. [45°]. Violet-black plates.

References.—BROMO-, BROMO-DI-NITRO-, CHLORO-, CHLORO-NITRO-, IODO-DI-, NITRO-, and NITROSO-DI-METHYLANILINE.

DIMETHYLANILINE - AZYLIN v. *Di-methyl-amido-benzene-azo-dimethylaniline*.

METHYL-ANISOL is the methyl ether of **CRESOL**.

(**B. 1**)-**METHYL-ANTHRACENE** $C_{15}H_{12}$ i.e.

(Börnstein); [200°] (Birukoff). Formed by distilling *erythro*-oxy-methyl-anthraquinone with zinc-dust (Birukoff, *B.* 20, 2070). Formed also by boiling *iso*-methylanthraquinone with zinc-dust and ammonia, and splitting off water from the resulting methyl-hydroxanthranol by boiling with xylene (Börnstein, *B.* 15, 1821). White plates.— $B^*C_6H_5(NO_2)OH$: red needles. Gives on oxidation methyl-anthraquinone [167°] and

the corresponding anthraquinone carboxylic acid. Forms a di-bromo-methyl-anthracene [148°].

Hexahydrate $C_{15}H_{14}$. [α : 65°]. Formed by reducing the dilactone of benzophenone dicarboxylic acid with phosphorus and hydrie iodide (Graebe a. Juillard, *A.* 242, 256). Plates. V. sol. alcohol, ether, and chloroform. Passed through a red-hot tube it yields a hydrocarbon [195°]. On oxidation it yields methylanthraquinone [154°].

(**B. 2**)-**Methyl-anthracene**

coal-tar oil, and hence is present in crude anthracene and phenanthrene (Japp a. Schultz, *B.* 10, 1049).

Formation.—1. By passing di-tolyl-methane through a red-hot tube (Weiler, *B.* 7, 1181).—2. By passing di-tolyl-ethane through a red-hot tube (O. Fischer, *B.* 7, 1191; 8, 675).—3. Apparently occurs among the products obtained by passing vapour of oil of turpentine through a red-hot tube (Schultz, *B.* 10, 84).—4. By the action of zinc-dust at high temperatures on chrysophanic acid $C_{15}H_8O_2(OH)_2$, on emodin $C_{15}H_8O_2(OH)$, (Liebermann, *B.* 8, 970; *A.* 183, 163), on aloin (in small quantity) (E. Schmidt, *B.* 8, 1275; *Ar. Ph.* [3] 8, 496), on the acid [4:1] $CH_3.C_6H_4.CO.C_6H_4.CO_2H$ (Gresly, *A.* 234, 238), on abietic acid (colophony), on gum benzoin (Ciamician, *B.* 11, 273), on chrysarobin (Liebermann a. Soidler, *A.* 212, 34), and on methyl-quinizarin (Nietzki, *B.* 10, 2013).—5. By boiling phenyl xylol ketone $C_6H_5.CO.CO.C_6H_5Me_{1:2:4}$ for a long time (Elbs, *J. pr.* [2] 35, 472). The isomeric $C_6H_5.CO.CO.C_6H_5Me_{1:2:5}$ condenses on boiling to the extent of 10 to 20 p.c. to (**B. 2**)-methyl-anthracene; dehydrating agents either stop the reaction or split off benzoic acid.

Properties.—Yellowish plates (from alcohol). Sublimes in large white plates, exhibiting blue fluorescence. Sl. sol. alcohol, ether, and H_2OAc , v. sol. $CHCl_3$, benzene, and CS_2 . Chromic acid in $HOAc$ oxidises it to anthraquinone carboxylic acid [282°]. Conc. HNO_3 added to its alcoholic solution forms methyl-anthraquinone. Bromine in CS_2 forms a di-bromo-derivative [156°] (Fischer), which yields, on further bromination, a tetra-bromo-derivative crystallising from toluene in needles. The picric acid compound melts at [93°] (Gresly).

Di-methyl-anthracene $C_{16}H_{14}$ i.e.

7-19. One of the products obtained by passing benzyl-mesitylene through a red-hot tube. Separated from the di-methyl anthracene [218°] which accompanies it in smaller quantity, by crystallisation from toluene, in which the compound, melting at 71°, is extremely soluble. Further purified by means of its picric acid compound (Louise, *Bl.* [2] 44, 180; *A. Ch.* [6] 6, 191). White needles, v. e. sol. cold benzene and toluene, m. sol. $HOAc$ and alcohol. On oxidation with CrO_3 in $HOAc$ it yields di-methyl-anthraquinone [158°]. The picric acid compound forms long red needles. Forms a grey compound with nitro-anthracene.

[219°]. One of the products of the passage of benzyl-mesitylene through a red-hot tube (Louise, *Bl.* [2] 44, 178). Rhomboidal plates, insol. cold alcohol, sl. sol. ether, ligroin, and acetic acid, v. sol. hot benzene and toluene. Forms small colourless leaflets when sublimed. Br in CS_2 forms a crystallised bromo-derivative. The picric acid compound crystallises in red needles. CrO_3 in HOAc oxidises it to a di-methyl-anthraquinone [170°]. Forms a green compound with nitro-anthracene.

Obtained by distilling with zinc-dust the tri-oxy-di-methyl-anthraquinone derived from *m*-xylene carboxylic acid, gallic acid, and H_2SO_4 (Birukoff, *B.* 20, 871). Plates. Oxidised by CrO_3 to a di-methyl-anthraquinone [112°].

[216°]. Obtained by treating a mixture of toluene (8 pts.), CS_2 (3 pts.), and chloroform (1 pt.) with $AlCl_3$ (2 pts.) (Elbs a. Wittich, *B.* 18, 848). With chromic acid it gives a quinone [162°]. Probably identical with the isomeride [219°].

[203°]. From [2:4:1] $C_6H_4Me_2 \cdot CO \cdot C_6H_4 \cdot CO \cdot H$ [1:2] by heating with red-hot zinc-dust (Gresly, *A.* 234, 238). Plates. Possibly identical with the isomeride [220°-226°].

Di-methyl-anthracene $C_6H_4 \begin{array}{c} \text{CH} \\ | \\ \text{CH} \end{array} C_6H_4Me_2$ [1:3]. [246°]. Formed by reduction of di-methyl-anthraquinone [183°] with zinc-dust and NH_3 . White plates, with bluish-green fluorescence. Its picrate forms garnet-red needles, decomposed by alcohol (Elbs a. Eurich, *B.* 20, 1363).

Di-methyl-anthracene $C_6H_4Me \begin{array}{c} \text{CH} \\ | \\ \text{CH} \end{array} C_6H_4Me$ [200°]. Formed from coal-tar xylene by chlorination at boiling temperature, and subsequently heating the resulting [3:1] $C_6H_4(CH_2)(CH_2Cl)$ with water at 210° (Van Dorp, *B.* 5, 674). White fluorescent plates. Yields on oxidation with chromic acid a quinone [158°]. Br gives a di-bromo-di-methyl-anthracene [154°]. Perhaps identical with the following isomeride.

Occurs in coal-tar (Zincke a. Wachen-dorff, *B.* 10, 1481). Formed from toluene, $AlCl_3$, and acetylene tetrabromide (Anschütz, *A.* 235, 179). Prepared by acting on toluene with methylene chloride in presence of $AlCl_3$ (Friedel a. Crafts, *Bl.* [2] 41, 828; *A. Ch.* [6] 11, 266). Scales. With CrO_3 in HOAc it gives dimethyl-anthraquinone [160°], which forms an orange

solution in H_2SO_4 . The picric acid compound crystallises in slender needles.

$C_6H_4Me \begin{array}{c} \text{CHMe} \\ | \\ \text{CHMe} \end{array} C_6H_4Me$ by distillation over red-hot zinc-dust (Anschütz, *A.* 235, 320), Greenish-yellow laminae (from benzene); m. sol. benzene, sl. sol. alcohol. Gives on oxidation di-methyl-anthraquinone [236°].

s-Di-methyl-anthracene dihydride C_6H_4 , *i.e.* $C_6H_4 \begin{array}{c} \text{CMeH} \\ | \\ \text{CMeH} \end{array} C_6H_4$ [181°]. From ethylidene bromide, benzene, and $AlCl_3$ (Anschütz, *A.* 235, 305). Yellow laminae (from alcohol). Sublimes in yellow needles. V. sol. benzene, CS_2 , and ether, sl. sol. cold alcohol and glacial HOAc. Distillation over red-hot zinc-dust gives anthracene. Oxidation gives anthraquinone. Bromine in HOAc gives $C_6H_4 \begin{array}{c} \text{CMeBr} \\ | \\ \text{CMeBr} \end{array} C_6H_4$, which crystallises from toluene in needles.

Picrate $C_6H_4 \cdot C_6H_4(NO_2)_2 \cdot OH$ [174°].

u-Di-methyl-anthracene dihydride $C_6H_4 \begin{array}{c} \text{CH}_2 \\ | \\ \text{CMe}_2 \end{array} C_6H_4$ [56°]. Formed by the action of HI and red phosphorus on dimethyl-anthron $C_6H_4 \begin{array}{c} \text{CO} \\ | \\ \text{CMe}_2 \end{array} C_6H_4$ at 150° (Hallgarten, *B.* 21, 2508). White crystals, sol. ether, benzene, and HOAc.

[1:2:3:5]. [236°] (W.); [243°] (G.). Obtained by distilling 'ψ-cumene-phthaloylio' acid $C_6H_4Me \cdot CO \cdot C_6H_4 \cdot CO \cdot H$ with zinc-dust (Gresly, *A.* 234, 239). Formed also by distilling tri-oxy-di-methyl-anthraquinone [244°] over zinc-dust (Wende, *B.* 20, 868). Exhibits green fluorescence.

Formed by boiling di-*p*-xylyl-ketone $C_6H_4Me \cdot CO \cdot C_6H_4Me$ for six hours, H_2O being eliminated. Colourless plates, with bluish-green fluorescence. Sublimes below 100°; slightly volatile with alcohol. V. sl. sol. cold alcohol, v. sol. ether. By CrO_3 and acetic acid it is oxidised to tri-methyl-anthraquinone [184°] (Elbs a. Olberg, *B.* 19, 409; *J. pr.* [2] 85, 489).

Tetra-methyl-anthracene C_6H_2 , *i.e.* [o. 280°]. A small quantity (3 g.) is formed from *m*-xylene (100 g.), Al_2Cl_6 , and acetylene tetrabromide (Anschütz, *A.* 235, 173). CrO_3 gives a substance (tetra-methyl-anthraquinone?) which forms needles [o. 300°].

Tetra-methyl-anthracene (?). [280°]. From *o*-xylene, Al_2Cl_6 , and acetylene tetrabromide (Anschütz, *A.* 235, 175). Fluorescent needles.

Tetra-methyl-anthracene (?). [280°]. Formed similarly from *p*-xylene (A.).

Tetra-methyl-anthracene $C_6H_2Me_4$ [168°]. Formed by the action of methylene chloride in presence of $AlCl_3$ on *m*-xylene, and in smaller

quantity on ψ -cumene (Friedel a. Crafts, *A. Ch.* [6] 11, 268). Crystallises from benzene. Gives a dark-red crystalline compound with picric acid. Conc. H_2SO_4 gives a yellow solution. CrO_3 in $HOAc$ oxidises it to tetra-methyl-anthraquinone [206°].

Tetra-methyl-anthracene dibromide

$C_6H_4Me_4 \begin{smallmatrix} CBrMe \\ CBrMe \end{smallmatrix} C_6H_4Me_4$. From the corresponding tetra-methyl-anthracene dihydride by bromination (Anschütz, *A.* 235, 321). Yellow needles; decomposes when heated.

Tetra-methyl-anthracene dihydride

$MeC_6H_3 \begin{smallmatrix} CMeH \\ CMeH \end{smallmatrix} C_6H_3Me$. [171°]. Obtained by the action of ethylidene chloride on toluene in presence of $AlCl_3$ (Anschütz, *A.* 235, 317). Pale-yellow trimetric laminae; $a:b:c = .675:1:1.924$ (from alcohol and $HOAc$); v. sol. benzene, sl. sol. $HOAc$, v. sl. sol. alcohol. Distillation over red-hot zinc-dust gives di-methyl-anthracene [244°]. Oxidation gives di-methyl-anthraquinone [236°].

Picrate $C_{18}H_{12}O_6(NO_2)_3.OH$. [165°]. Red glistening needles.

Hexa-methyl-anthracene $C_{18}H_{12}Me_6$. [c. 220°]. One of the products of the action of methylene chloride on ψ -cumene in presence of $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 11, 272). Not volatile at 440°. The alcoholic solution gives with picric acid a brownish-black pp. [203°]. Conc. H_2SO_4 forms a red solution, becoming colourless after absorbing moisture.

References.—DI-BROMO-METHYL-ANTHRACENE and AMIDO-METHYL-ANTHRACENE DIHYDRIDE and DIBROMIDE.

DI-METHYL-ANTHRAMINE $C_{18}H_{12}.NMe_2$. Di-methyl-anthracylamine. [155°]. Formed by heating the methylo-hydrate. Thin golden plates. Soluble in alcohol with a green fluorescence.

Salts.— $BHCl$: colourless plates, decomposed by water.— $B_2H_2Cl_2.PtCl_4$: yellow pp.

Methylo-iodide $B'MeI$. [215° uncor.]. Formed by heating anthramine with methyl iodide at 100°. Flat needles, sol. hot water, sl. sol. cold, nearly insol. alcohol.

Methylo-chloride-platinum salt

$B'_2Me_2Cl_2.PtCl_4$: yellow crystalline pp.

Methylo-hydrate $B'Me(OH)_2$: strongly alkaline. Formed by the action of Ag_2O on the iodide; on boiling the aqueous solution it decomposes into di-methyl-anthramine and methyl alcohol (Bollert, *B.* 16, 1636).

METHYL-ANTHRANILIC ACID v. AMIDO-TOLUIC ACID.

(B. 1)-METHYL-ANTHRAQUINONE

$C_{18}H_{10}O_2$ i.e. $C_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} C_6H_4Me$ [5 1]. Mol. w. 222. [154°] (Graebe); [167°] (Birukoff); [176°] (Börnstein). Formed by oxidising (B. 1)-methyl-anthracene with CrO_3 and $HOAc$ (Birukoff, *B.* 20, 2070). Formed also by oxidising

(B. 1)-methyl-anthracene hexahydride (Graebe, *A.* 242, 256). The same, or the following, methyl-anthraquinone is a by-product in the preparation of anthraquinone (Wachendorff a. Zinke, *B.* 10, 1485; Börnstein, *B.* 15, 1820). Small needles (from dilute $HOAc$). V. e. sol. alcohol and benzene.

(B. 2)-Methyl-anthraquinone

$C_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} C_6H_4Me$ [5 2]. [163°] (F.); [172°] (E.); [177°] (Römer a. Link, *B.* 16, 695).

Formation.—1. By warming an alcoholic solution of (B. 2)-methyl-anthracene with nitric acid, pp. with water, and subliming (O. Fischer, *B.* 8, 675).—2. In small quantity by boiling phenyl *m*-xylyl ketone (Elbs, *J. pr.* [2] 35, 471). 3. By warming $[4:1]CH_3.C_6H_4.CO.C_6H_4.CO_2H$ with H_2SO_4 at 170° for ten minutes (Gresly, *A.* 234, 239).

Properties.—Yellow needles. Sublimes in almost colourless needles. V. sol. alcohol, benzene, and $HOAc$ (R. a. L.); according to Fischer, however, it is sl. sol. these solvents. Conc. H_2SO_4 forms a blood-red solution which becomes violet on heating. When heated with zinc-dust it yields methyl-anthracene [203°]. With fuming H_2SO_4 it yields a disulphonic acid, which on fusion with potash forms di-oxy-methyl-anthraquinone (methyl-alizarin) [252°] (Fischer).

Isomeride of Methyl-anthraquinone v. METHANTHRENE.

Di-methyl-anthraquinone $C_{18}H_{12}O_2$ i.e.

$C_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} C_6H_4Me_2$ [1 6:2:4] ? [158°]. Obtained by oxidising the corresponding di-methyl-anthracene [71°]. Formed also by heating benzoyl-mesitylenic acid $C_6H_5.CO.C_6H_4Me_2.CO_2H$ with P_2O_5 and subliming the product (Louise, *A. Ch.* [6] 6, 193, 228; *Bl.* [2] 44, 181). Yellow acicular prisms (from chloroform-acetone) or needles (by sublimation). Insol. water, sl. sol. alcohol, sol. chloroform and acetone. With zinc-dust and KOH it gives an intense red colour. This di-methyl-anthraquinone ought theoretically to be identical with those melting at 180° and 112° (v. *infra*).

Di-methyl-anthraquinone $C_{18}H_{12}O_2$. [170°]. Obtained by oxidising di-methyl-anthracene [219°] with CrO_3 in $HOAc$ (Louise, *A. Ch.* [6] 6, 189; *Bl.* [2] 44, 180). Yellow needles (from alcohol). With zinc-dust and KOH it gives a characteristic red tint, which disappears on heating.

Di-methyl-anthraquinone

$C_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} C_6H_4Me_2$ [1 6:3:4]. [183°].

Obtained by heating *o*-xylyl-phenyl-ketone-carboxylic acid (*o*-xylyl-*o*-benzoic acid) $[3:4:1]C_6H_4Me_2.CO.C_6H_4.CO_2H$ [1:2] with conc. H_2SO_4 . By HNO_3 (S.G. 1.2) at 220° it is oxidised to anthraquinone-di-carboxylic acid [340°] (Elbs a. Eurich, *B.* 20, 1361).

Di-methyl-anthraquinone

$C_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} C_6H_4Me_2$ [1 6:2:4]. [180°].

Formed by heating *m*-xylyl-phenyl-ketone-*o*-carboxylic acid (*m*-xylyl-*o*-benzoic acid) $[2:4:1]C_6H_4Me_2.CO.C_6H_4.CO_2H$ [1:2] with conc. H_2SO_4 ; the yield is 60 to 70 p.c. of the theoretical (Gresly, *A.* 234, 240; Elbs a. Günther, *B.* 20, 1864). Small needles, al. sol. benzene

U.

and alcohol. By dil. HNO₃ it is oxidised to anthraquinone *m*-di-carboxylic acid [above 330°]. Reduced by zinc-dust and ammonia to a hydrocarbon [85°] which forms with picric acid reddish-brown scales [135°].

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_2$ [$\frac{1}{6}$:2:5]. [118°]. Formed by warming [4:1:2] $\text{C}_6\text{H}_4\text{Me}_2$, CO , C_6H_4 , CO , H [2:1] with conc. H_2SO_4 at 120° (Gresly, A. 234, 240).

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_2$ [$\frac{1}{6}$:2:4]? [112°]. Obtained by oxidising the di-methyl-anthracene [220°–226°] (Birukoff, B. 20, 871).

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_2$. [162°]. Obtained by oxidising di-methyl-anthracene [216°] (Elbs a. Wittich, B. 18, 348).

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\text{Me}\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}$. [236°]. Formed by oxidation of di-methyl-anthracene [244°]. Pale-yellow needles, sl. sol. HOAc, v. sl. sol. alcohol (Anschütz, A. 235, 321).

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\text{Me}\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}$. [155°]. Obtained by oxidising the di-methyl-anthracene occurring in coal-tar xylene (Wachendorff a. Zincke, B. 10, 1482). Small light-yellow needles (from dilute alcohol). May be sublimed. M. sol. alcohol, ether, and HOAc.

Di-methyl-anthraquinone

$\text{C}_6\text{H}_4\text{Me}\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}$. [160°]. Obtained by oxidising the di-methyl-anthracene formed from toluene, methylene chloride, and AlCl_3 (Friedel a. Crafts, A. Ch. [6] 11, 266). Forms an orange solution in H_2SO_4 . Probably identical with the preceding.

Tri-methyl-anthraquinone

$\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_3$. [Me:Me:Me = 1:2:4]. [161°]. Formed by warming ψ -cuminoyl-benzoic acid $\text{C}_6\text{H}_4\text{Me}_3\text{CO}$, C_6H_4 , CO , H for a short time with conc. H_2SO_4 (Gresly, A. 234, 240). Needles.

Tri-methyl-anthraquinone

$[\frac{2}{5}:\frac{1}{6}]\text{C}_6\text{H}_4\text{Me}_3\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_3$ [$\frac{1}{6}$:3]. [184°]. Formed by oxidation of the tri-methyl-anthracene obtained from di-*p*-xylol ketone (Elbs a. Olberg, B. 19, 409).

References. — AMIDO-, NITRO-, and OXY-METHYL-ANTHRAQUINONES.

METHYL-ANTHRAQUINONE CARBOXYLIC ACID

LICACIO $\text{C}_6\text{H}_4\text{O}_2$, i.e. $\text{C}_6\text{H}_4\text{Me}\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{CO}_2\text{H}$. [246°]. Occurs among the products of the oxidation of coal-tar di-methyl-anthracene by CrCl_3 in HOAc (Wachendorff a. Zincke, P. 10, 1483). Small needles (by sublimation); v. sol. hot alcohol.

Di-methyl-anthraquinone carboxylic acid

$\text{C}_6\text{H}_4\text{O}_2$, i.e. $\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{H}$. [240°]. Formed by heating ψ -cuminoyl-benzoic acid $\text{C}_6\text{H}_4\text{Me}_2\text{CO}$, C_6H_4 , CO , H [2:1] with fuming H_2SO_4 (Gresly, A. 234, 241). Small needles. V. sol.

alkalis, sl. sol. alcohol and benzene. May be sublimed.

DI-METHYL-ANTHRARUFIN v. **DI-OXY-DI-METHYL-ANTHRAQUINONE**.

DI-METHYL-ANTHRONE $\text{C}_{16}\text{H}_{10}\text{O}$ i.e.

$\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{CMe}_2\text{C}_6\text{H}_4$. [94°]. Formed by the action of MeI and KOH aq on anthranol (Hallgarten, B. 21, 2508). Transparent crystals, v. sol. benzene, ether, sl. sol. petroleum ether. Converted by the action of HI and red phosphorus into di-methyl-anthracene dihydride.

METHYL-ARBUTIN v. **ARBUTIN**.

METHYL ARSENATE Me_3AsO_4 . (214°).

S.G. 1.559. Formed from Ag_3AsO_4 and MeI (Crafts, Bl. [2] 14, 99).

METHYL ARSENITE Me_3AsO_3 . (129°).

S.G. 1.428. V.D. 6.01. From AsCl_3 and NaOMe (Crafts, Bl. [2] 14, 104). When arsenious acid is dissolved in aqueous NaOH and treated with alcoholic MeI the product is not mono-methyl arsenite but methane arsonic acid $\text{CH}_3\text{AsO}(\text{OH})_2$ (Klinger, A. 249, 149; cf. vol. i. p. 317).

METHYL-ARSINE v. **Organic ARSENIC COMPOUNDS**.

METHYL-ATROLACTIC ACID v. **OXY-TOLYL-PROPIONIC ACID**.

METHYL-ATROPIC ACID v. **PHENYL-CROTONIC ACID**.

METHYL-AURIN $\text{C}_{20}\text{H}_{16}\text{O}_4$ aq. A by-product in the preparation of aurin (Zulkowsky, A. 194, 131; 202, 210; M. 3, 476). Brick-red crystals with green lustre (from 60 p.c. alcohol). Its alcoholic solution is yellowish-red, and becomes crimson on addition of alkalis. It loses aq at 100°, but does not melt below 200°. HCl added to its dilute alcoholic solution ppts. $\text{C}_{20}\text{H}_{16}\text{ClO}_4$ as red crystals with blue reflex. On heating with water in sealed tubes at 245° methyl-aurin is split up into *p*-cresol and di-oxy-benzo-phenone. Alkaline KMnO_4 oxidises methyl-aurin to $\text{C}_{20}\text{H}_{16}\text{O}_6$. Potash-fusion forms *p*-oxy-benzoic acid. Zinc-dust and HOAc reduce it to methyl-leucaurin $\text{C}_{20}\text{H}_{18}\text{O}_3$, which crystallises in long colourless needles. H_2SO_4 forms red crystals of $(\text{C}_{20}\text{H}_{16}\text{O}_4)_2\text{H}_2\text{SO}_4$ which are blue by reflected light. Bromine in HOAc forms crystals of $\text{C}_{20}\text{H}_{12}\text{Br}_2\text{O}_4\text{HBr aq}$, which have a steel-blue reflex.

METHYL-AZELAYC ACID v. **OCTANE DICARBOXYLIC ACID**.

METHYL-DIAZO COMPOUNDS v. **Di-Azo COMPOUNDS**.

TETRA-METHYL-TETRAZONE $\text{C}_4\text{H}_4\text{N}_4$ i.e. $(\text{CH}_3)_4\text{N}_4\text{N}_4\text{N}_4(\text{CH}_3)_4$. (130°). Prepared by the oxidation of dimethyl-hydrazine in ethereal solution with HgO (Renouf, B. 13, 2173). Oily fluid. Explodes with violence if heated above 130°. Alkaline in reaction. Reduces AgNO_3 to a silver mirror. It is decomposed by boiling aqueous acids into dimethylamine, methylamine, formic acid, and nitrogen.

Salts. — The picrate $\text{B/C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$ forms yellow prisms. V. sol. water, sl. sol. alcohol. The other salts are also easily soluble in water.

METHYL-iso-BARBITURIC ACID $\text{C}_4\text{H}_4\text{N}_4\text{O}_3$. Formed by treating nitro-methyl-uracil

$\text{CO} \begin{smallmatrix} \text{NMe.CH} \\ \text{NH} \end{smallmatrix} \text{CO} \text{C.NO.}$ with tin and HCl (Lehmann, A. 253, 80). Needles, v. sol. cold water.

Di-methyl-barbituric acid v. *Di-methyl derivative of BARBITURIC ACID*, vol. i. p. 439.

METHYL-BENZAMIDES v. *Benzoyl derivatives of METHYLAMINES*.

METHYL-BENZENE v. TOLUENE.

Di-methyl-benzene v. XYLENE.

Tri-methyl-benzene v. ψ -CUMENE, MESITYLENE, and HEMIMELLITHENE.

Tetra-methyl-benzene v. DURENE.

Penta-methyl-benzene C_7H_{10} i.e. C_6HMe_5 . Mol. w. 148. [52°]. (231° i.V.). V.D. 5.27 (calc. 5.12). H.F. 31,900. H.C. 1,554,100 (Stohmann, Kleber, A. Langbein, J. pr. [2] 40, 83). One of the products of the action of MeCl on benzene or toluene in presence of AlCl_3 (Friedel a. Crafts, A. Ch. [6] 1, 472; Ador a. Rilliet, B. 12, 332). Formed also in like manner by the action of MeCl and AlCl_3 on tri-methyl-benzenes at 100°–110°; the fraction (220°–235°) on crystallisation from alcohol deposits C_6Me_5 first, and the penta-methyl-benzene remaining in the mother-liquor may then be purified by means of its sulphamide (Jacobsen, B. 20, 896). Penta-methyl-benzene is a by-product in the formation of tetramethyl-benzene by the action of MeI and AlCl_3 on ψ -cumene (Claus, J. pr. [2] 38, 231).

Properties.—Flat prisms; v. e. sol. alcohol.

Reactions.—1. Bromine in CHCl_3 forms $\text{C}_6\text{Me}_5\text{Br}$. [163°] (292° i.V.) (F. a. C.; Jacobsen, B. 20, 898).—2. AgNO_3 and vapour of Br forms di-bromo-*c*-durene [202°] (Gottschalk, B. 20, 3288).—3. ClSO_3H forms the sulphone and sulphochloride (Jacobsen).—4. Cold conc. H_2SO_4 does not form the corresponding sulphonic acid, but yields *c*-tetra-methyl-benzene sulphonic acid and hexa-methyl-benzene (J.).—5. KMnO_4 forms benzene penta-carboxylic acid (F. a. C.).—6. Fuming nitric acid forms di-nitro-*c*-tetra-methyl-benzene [178°] (Gottschalk, B. 20, 3287). Dilute nitric acid acting on its solution in benzene produces tetra-methyl-benzoic acid [165°].—7. Heating with AlCl_3 forms isodurene, C_6Me_5 , and other hydrocarbons (Jacobsen, B. 18, 340).—8. ClCONH_2 and AlCl_3 convert C_6HMe_5 dissolved in CS_2 into the amide of penta-methyl-benzoic acid (Jacobsen, B. 22, 1219).

Picric acid compound $\text{C}_6\text{HMe}_5\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$. [181°]. Golden-yellow prisms.

Hexa-methyl-benzene $\text{C}_{12}\text{H}_{18}$ i.e. C_6Me_6 . Mol. w. 162. [164°] (F. a. C.); [166°] (J.). (264°). S. (95 p.c. alcohol) 2 at 0°. V.D. 5.73 (calc. 5.61) (F. a. C.); 5.68 (H.). H.C.v. 1,709,600. H.C.p. 1,712,200. H.F. 36,800 (Stohmann, Kleber, A. Langbein, J. pr. [2] 40, 84).

Formation.—1. The final product of the action of MeCl on benzene or toluene in the presence of AlCl_3 (Friedel a. Crafts, A. Ch. [6] 1, 467; O. R. 91, 257; Ador a. Rilliet, B. 12, 332).—2. From *o*-di-chloro-benzene, MeCl, and AlCl_3 at 100° (Friedel a. Crafts, A. Ch. [6] 10, 411).—3. A by-product in the formation of (1,2,3,4)-tetra-methyl-benzene by the action of MeI and AlCl_3 on ψ -cumene (Claus, J. pr. [2] 38, 231).—4. By heating dimethylaniline methyl-iodide at 330° (Hofmann, B. 5, 721).—5. Said to be a product of the action of fused ZnCl_2 on sugar (C. J. 34, 843; D. P. J. 237, 146).—6. Formed as a

by-product in the preparation of cumidine by heating xylidine hydrochloride with methyl alcohol; also in small quantity by the action of methyl alcohol at a high temperature on aniline hydrochloride (Hofmann, B. 18, 1729).—7. By dropping methyl alcohol upon strongly-heated ZnCl_2 (Le Bel a. Greene, Am. 2, 21).—8. By pouring acetone upon fused ZnCl_2 (H. Greene, C. R. 87, 931).—9. By shaking crotonylene CMe_2CMe with H_2SO_4 (3 pts.) diluted with water (1 pt.) (Favorsky, J. pr. [2] 37, 384; Lwoff a. Almédingen, BL [2] 37, 493).—10. Together with other products by the prolonged action of conc. H_2SO_4 upon durene (Jacobsen, B. 19, 1211).—11. A product of the action of cold conc. H_2SO_4 on penta-methyl-benzene (Jacobsen, B. 20, 901).

Properties.—Colourless plates (from alcohol) or prisms (from benzene); insol. water, al. sol. cold, v. sol. hot, alcohol, v. sol. benzene. Forms iridescent plates on sublimation. Does not dissolve in conc. H_2SO_4 .

Reactions.—1. Bromine at 100° yields $\text{C}_{12}\text{H}_{12}\text{Br}_2$ [255°] (F. a. C.); [227°] (H.).—2. KMnO_4 oxidises it at a low temperature to mellitic acid.—3. Dilute nitric acid yields *c*-tetra-methyl-benzene dicarboxylic acid (Jacobsen, B. 22, 1216).—4. When heated with AlCl_3 at 200° a gas is given off and penta-methyl-benzene, durene (Friedel a. Crafts, C. R. 100, 692), isodurene, tri-methyl-benzenes, xylenes, toluene, and benzene are formed (Jacobsen, B. 18, 339).—5. PCl_5 forms hexa-chloro-hexa-methyl-benzene (q. v.).

Picric acid compound

$\text{C}_6\text{Me}_5\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$. [169°]. Golden plates.

METHYL-BENZENE CARBOXYLIC ACID v. TOLUIC ACID.

Di-methyl-benzene carboxylic acid v. MESITYLENIC and DI-METHYL-BENZOIC ACIDS.

Tri-methyl-benzene carboxylic acid v. ψ -CUMINIC ACID.

Methyl-benzene dicarboxylic acid v. UVITIC ACID, METHYL-ISOPHTHALIC ACID, METHYL-TEREPHTHALIC ACID, and TOLUENE DICARBOXYLIC ACID.

Di-methyl-benzene dicarboxylic acid v. DI-METHYL-ISOPHTHALIC and DI-METHYL-TEREPHTHALIC ACIDS.

Tri-methyl-benzene dicarboxylic acid $\text{C}_6\text{HMe}_3(\text{CO}_2\text{H})_2$. Obtained by oxidising $\text{C}_6\text{HMe}_3\text{CO}_2\text{C}_2\text{H}_5$ with KMnO_4 in alkaline solution (Ador a. Meyer, J. 1879, 562). Needles (from water).—BaA' aq. Slender needles; almost insol. water.

Tetra-methyl-benzene dicarboxylic acid $\text{C}_6\text{Me}_4(\text{CO}_2\text{H})_2$ [6:5:4:3:2:1]. [249°]. Formed by boiling C_6Me_5 with dilute HNO_3 (Jacobsen, B. 22, 1215). Small needles (from hot water) or prisms (from alcohol). Yields *c*-durene when distilled with lime.—BaA' 2aq.

DI-METHYL-BENZENE GLYCOL v. DI- α -OXY-XYLENE.

METHYL-BENZENE SULPHINIC ACID v. TOLUENE SULPHINIC ACID.

Tri-methyl-benzene sulphinic acid $\text{C}_6\text{H}_3\text{Me}_3(\text{SO}_2\text{H})$ [1:3:4:6]. [98°]. Long needles (from water).—NaA'.—BaA'. S. 5 at 7°. Thin plates.—AgA' (Radloff, B. 11, 82).

METHYL-BENZENE SULPHONIC ACID v. TOLUENE SULPHONIC ACID.

Di-methyl-benzene sulphonic acid v. XYLENE SULPHONIC ACID.

c-Tri-methyl-benzene sulphonic acid
 $C_9H_7Me_3(SO_3H)$ [1:2:3:5]. *Hemimellitene sulphonic acid*. Formed by sulphonation of hemimellitene (Jacobsen, B. 15, 1858; 19, 2517). Crystallises from dilute H_2SO_4 in six-sided plates or tables (containing aq).— NaA' aq: tables, v. sol. hot, m. sol. cold, water.— BaA' : brittle plates, v. sl. sol. water.

Amide $C_9H_7Me_3SO_3NH_2$. [196°]. Prisms or needles. Less soluble in alcohol than the amide of ψ -cumenene sulphonic acid.

Isomerides v. ψ -CUMENE SULPHONIC ACID and MESITYLENE SULPHONIC ACID.**Tetra-methyl-benzene sulphonic acid v. DURENE SULPHONIC ACID.**

Penta-methyl-benzene sulphonic acid
 $C_{10}H_6Me_5SO_3H$. Obtained by treating penta-methyl-benzene with $ClSO_3H$ and treating the product with $NaOH$ to convert the $C_{10}H_6Me_5SO_3Cl$ first formed into $C_{10}H_6Me_5SO_3Na$ (Jacobsen, B. 20, 899). In the action of $ClSO_3H$ on $C_{10}H_6Me_5H$ a sulphone [98-5°], crystallising from petroleum-ether in needles, is also formed. The free acid, liberated by shaking the sodium salt with light petroleum and H_2SO_4 , at once undergoes hydrolysis, $C_{10}H_6Me_5$ dissolving in the petroleum.

Salts.— $A'Na$: tables (from neutral aqueous solution) or plates (from hot, dilute, $NaOH$); sl. sol. cold water, m. sol. hot water, insol. cold, dilute $NaOH$.— $A'K$: plates (from hot water).— $A'Ba$: plates, v. sl. sol. hot water.— $A'Ca$: plates.— $A'Ag$: plates, v. sl. sol. cold, m. sol. hot water.— $A'Cu$: greenish-white tables; sl. sol. water.

Chloride. [82°]. Plates (from $EtOH$), or prisms (from Et_2O); v. sol. $EtOH$ and Et_2O .

Amide. [186°]. Prisms; v. e. sol. hot, m. sol. cold, $EtOH$; insol. water. $KMnO_4$ produces a sulphamic acid [c. 265°].

METHYL-BENZGLYCOCYAMIDINE v. BENZOREATININE.**METHYL-BENZGLYCOCYAMINE v. BENZCREATIN.****TETRA-METHYL-BENZIDINE v. TETRA-METHYL-DI- ψ -AMIDO-DIPHENYL.****METHYL-BENZIL v. PHENYL TOLYL DIKONE.****METHYL-BENZOIC ACID v. TOLUIC ACID.**

Di-methyl-benzoic acid $C_9H_7O_2$, i.e.
 $C_9H_6Me_2CO_2H$ [6:2:1]. *m-Xylene c-carboxylic acid*. [97°-99°]. Formed by fusing potassium *m*-xylene c-sulphonate with sodium formate (Jacobsen, B. 11, 21). Short needles (from water). Forms *m*-xylene when distilled with lime.

Di-methyl-benzoic acid
 $C_9H_7Me_2CO_2H$ [4:2:1]. *m-Xylene i-carboxylic acid*. *Xylylic acid*. *Xyloic acid*. [126°]. (267°) at 727 mm.

Formation.—1. By the oxidation of ψ -cumene by dilute nitric acid, being separated from the accompanying $C_9H_7Me_2CO_2H$ [5:2:1] through the greater solubility of its Ca salt (Fittig a. Laubinger, A. 151, 269).—2. By treating bromo-*m*-xylene with sodium and CO_2 (Kekulé, A. 187, 186).—3. By warming its nitrile with H_2SO_4 (85 p.c.) and heating the resulting amide with conc. $HClAq$ at 170° (Birukoff, B. 20, 871; A. 240, 296).—4. By heating its diphenylamius

with $HClAq$ (v. *infra*).—5. By decomposing its chloride (v. *infra*) with water.

Properties.—Slender needles (from water) or monoclinic prisms (from alcohol). May be sublimed. Almost insol. cold water, sl. sol. hot water, v. sol. hot alcohol. Gives *m*-xylene when heated with lime. Chromic acid mixture oxidises it to $C_9H_6Me_2(CO_2H)_2$ [3:1:4].

Salts.— CaA' , 2aq: monoclinic prisms, v. sol. water.— BaA' , 8aq?— AgA' .

Chloride $C_9H_7Me_2COCl$. [25-5°]. (235°). Formed by passing $COCl_2$ into *m*-xylene containing $AlCl_3$, and heating to 100° (Ador a. Meyer, B. 12, 1968).

Amide $C_9H_7Me_2CONH_2$. [180°]. Formed by warming the nitrile with H_2SO_4 (85 p.c.). Formed also by the action of NH_3 on *m*-xylene in presence of $AlCl_3$ (Gattermann, A. 214, 53). Formed also by passing gaseous $HCNO$ and HCl gas into *m*-xylene containing $AlCl_3$ on the water-bath (Gattermann a. Rossolym, B. 23, 1196). Long shining needles (from water). Almost insol. cold water, v. sol. alcohol.

Anilide $C_9H_7Me_2CONHPh$. [138-5°]. Crystals, v. sl. sol. hot water.

Diphenylamide $C_9H_7Me_2CONPh_2$. [142°]. Formed from *m*-xylene and NPh_2COCl in presence of $AlCl_3$ (Lellmann a. Bonhöffer, B. 20, 2120). Monoclinic crystals, v. e. sol. hot alcohol, $HOAc$, and chloroform, sl. sol. hot ether, v. sl. sol. hot petroleum-ether.

Nitrile $C_9H_7Me_2CN$. [25°]. (221°). S.G. 12.9871 (Hinrichsen, B. 21, 3082). V.D. 4.64.

Formation.—1. By heating the formyl derivative of *m*-xylidine with zinc-dust; the yield being about 12 p.c. (Gasiorovsky a. Merz, B. 18, 1012).—2. By distilling the corresponding $PO(OC_2H_5)_2$, with KCy ; the yield being 15 p.c. (Kreysler, B. 18, 1713).—3. From *m*-xylidine by Sandmeyer's reaction (Birukoff, B. 20, 871). **Properties.**—Triclinic crystals (from dilute alcohol). Volatile with steam. Yields benzyl-di-methyl-amine on reduction.

Amidoxim $C_9H_7Me_2C(NH):NOH$. [178°]. *Xylenyl-amidoxim*. Formed by the action of hydroxylamine on the nitrile at 85° (E. Oppenheimer, B. 22, 2143). White needles, v. sol. alcohol, ether, chloroform, and hot water, sl. sol. cold water. **Reactions.**—1. EtI acting on its Na derivative forms $C_9H_7Me_2C(NH_2):NOEt$ which crystallises in white needles, [172°], v. sol. alcohol, ether, chloroform, benzene, and boiling water, sl. sol. cold water. Excess of HCl converts the ethyl derivative into $C_9H_7Me_2CCl:NOEt$, a yellow aromatic oil.—2. *Chloral* forms a compound $CCl_3CHO(C_9H_7Me_2C(NH_2):NOH)$ [112°] crystallising in white scales, sol. alcohol and ether but decomposed by water and dilute acids. 3. $ClCO_2Et$ acting on the amidoxim in chloroform forms $C_9H_7Me_2C(NH_2):NOCO_2Et$ [148°] which crystallises in white needles, v. sol. alcohol, ether, and chloroform, sl. sol. ligroin. It is converted by heat into $C_9H_7Me_2C \begin{smallmatrix} N \\ \diagup \quad \diagdown \\ O \end{smallmatrix} CO$ which crystallises in needles [182°], v. sol. alcohol and ether.—4. *Potassium cyanate* acting on the hydrochloride of the amidoxim forms $C_9H_7Me_2C(NH):NH.CO.NH_2$ [158°] which crystallises from dilute alcohol in white scales, and forms an unstable platinumochloride.—5. *Phenyl cyanate* at 100° reacts forming

$C_6H_5Me_2C(OH).NH.CO.NHPh$ [138°] which crystallises from alcohol in light-yellow scales, sol. acids, alcohol, ether, chloroform, benzene, and hot water.—6. *Phenyl thio-carbimide* at 100° forms $C_6H_5Me_2C(OH).NH.CS.NHPh$ [150°], sol. alcohol, ether, benzene, boiling water, and acids.—7. Heating with Ac_2O forms the

azoxim $C_6H_5Me_2C \begin{smallmatrix} N.O \\ \diagup \quad \diagdown \\ N \end{smallmatrix} > C_6H_5$ [89°].—

8. *Succinic anhydride* forms the azoxim $C_6H_5Me_2C \begin{smallmatrix} N.O \\ \diagup \quad \diagdown \\ N \end{smallmatrix} > C_6H_4.CH_2.CO_2H$ which forms long white needles, [112°], v. sol. alcohol, ether, benzene, $CHCl_3$, and hot water, and yields crystalline salts.

Acetyl derivative of the *amidoxim* $C_6H_5Me_2C(NOAc)NH_2$ [189°]. Small white needles, v. sol. alcohol and chloroform, sl. sol. ether (Oppenheimer, *B.* 22, 2445).

Benzoyl derivative of the *amidoxim* $C_6H_5Me_2C(NO_2)NH_2$ [158°]. White crystals, v. sol. alcohol, ether, and chloroform, sl. sol. water and ligroin. Converted by heat into

$C_6H_5Me_2C \begin{smallmatrix} N.O \\ \diagup \quad \diagdown \\ N \end{smallmatrix} > C_6H_5$, which crystallises in faintly yellow scales, v. sol. alcohol, ether, and chloroform, volatile with steam (Oppenheimer, *B.* 22, 2444).

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [5:2:1]. *p*-Xylene carboxylic acid. [132°]. (268° i.v.).

Formation.—1. From bromo-*p*-xylene by treatment with $ClCO_2Et$ and sodium-amalgam, the resulting ether being then saponified (Jacobsen, *B.* 14, 2111).—2. By oxidation of methyl xylol ketone $CH_3.CO.C_6H_4Me_2$ [1:2:5] by dilute HNO_3 , or by $KMnO_4$ (Claus, *B.* 18, 1858; 19, 8183).—3. From its amide.

Properties.—Large needles (from alcohol); v. sl. sol. hot water, v. e. sol. alcohol. Volatile with steam. Yields $C_6H_5Me(CO_2H)_2$ [2:5:1] on oxidation.

Salts.— CaA' , 2aq: crusts, m. sol. water.— BaA' , 4aq: small needles.

Amide $C_6H_5Me_2CONH_2$ [186°]. Formed by the action of $Cl.CO.NH_2$ (or of $HNCO$ and HCl) on *p*-xylene in presence of $AlCl_3$ (Gattermann, *A.* 244, 54; *B.* 23, 1199). Colourless needles (from water); m. sol. hot water; v. e. sol. alcohol.

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [3:2:1]. *o*-Xylene *c*-carboxylic acid. *Hemimellitithylic acid*. [144°]. Formed by the oxidation of hemimellitene $C_6H_5Me_2$ [3:2:1] by dilute nitric acid (Jacobsen, *B.* 19, 2518). *Phisms* (from hot alcohol) or plates (from dilute alcohol). Volatile with steam; v. sl. sol. hot water, insol. cold water. Yields *o*-xylene when distilled with lime. CaA' , aq. Long prisms, m. sol. cold water.

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [4:3:1]. *o*-Xylene *i*-carboxylic acid. [165°]. Obtained by boiling its amide for 2 days with caustic potash solution. Formed also, together with the isomeric *m*-xylene *i*-carboxylic acid [126°] (v. *supra*), by oxidising ψ -cumene with dilute HNO_3 (Fittig a. Laubinger, *A.* 151, 275). Its ether is formed by the action of sodium-amalgam on a mixture of bromo-*o*-xylene and $ClCO_2Et$ (Jacobsen, *B.* 17, 2374). Prisms (from alcohol); almost insol. cold water, v. sl. sol. boiling water, v. e. sol. alcohol. Gives *o*-xylene when distilled with lime. Gives $C_6H_5Me(CO_2H)_2$

[3:4:1] on oxidation with dilute nitric acid.— CaA' , 3½aq. Needles.— BaA' , 4aq. Needles, v. sol. water.

Amide $C_6H_5Me_2CONH_2$ [181°]. Formed by the action of $NH_4.COCl$ on *o*-xylene in presence of $AlCl_3$ (Gattermann, *A.* 244, 52). Long shining needles (from water). The amide obtained from *o*-xylene, gaseous cyanic acid, HCl , and $AlCl_3$, melts at 165° (Gattermann a. Rossolym, *B.* 23, 1199).

Diphenylamide $C_6H_5Me_2CONPh_2$ [136°]. From $NPh_2.COCl$, *o*-xylene, and $AlCl_3$ (Leilmann a. Bonhöffer, *B.* 20, 2119). Small prisms; v. sol. hot alcohol, sl. sol. ether and ligroin.

Nitrile $C_6H_5Me_2CN$ (232°). V.D. 4.61. Formed by fusing potassium *o*-xylene sulphonate with KCy (Jacobsen, *B.* 11, 23). Formed also by heating the corresponding xylepyl phosphate $PO(OC_6H_4Me_2)_3$ with KCy , the yield being 20 p.c. (Kreysler, *B.* 18, 1711). Liquid, miscible with alcohol and ether.

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$ [5:3:1] is described as *MESITYLENIC ACID*.

Di-methyl-benzoic acid $C_6H_5Me_2CO_2H$? *Lauroxylic acid*. [155°]. Produced by the action of dilute nitric acid on laurene $C_{12}H_{22}$ (Fittig, Köbrich, a. Jilke, *A.* 145, 151). Hard nodules (from alcohol). Nearly insol. cold, sl. sol. boiling, water, v. sol. alcohol. Yields acetic acid on oxidation with chromic acid mixture.— BaA' , 4aq. Concentrically-grouped needles, v. sol. water.— CaA' , 4aq.— AgA' . White pp.; may be crystallised from water.

Tri-methyl-benzoic acid v. ψ -CUMINIC ACID. Another tri-methyl-benzoic acid, *Hemimellitithene carboxylic acid*, is described as *c*-CUMINIC ACID.

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [5:4:3:2:1]. [165°] (G.); [150°] (C.). (c. 270°). Formed by oxidising penta-methyl-benzene, dissolved in benzene, with dilute nitric acid (Gottschalk, *B.* 20, 3286). Formed also by oxidising tetra-methyl-phenyl methyl ketone or tetra-methyl-phenyl-acetic acid with $KMnO_4$ (Claus, *J. pr.* [2] 88, 234). Needles (G.), m. sol. hot water, v. e. sol. alcohol, ether, benzene, CS_2 , and chloroform (C.). Its alkaline salts are very soluble. The Ag salt is v. sl. sol. water. The cupric salt forms light-green plates.— BaA' , 2aq. Plates or nodules, v. sol. water and alcohol (G.).— BaA' , 6aq (C.).— CaA' , 3aq (C.).— NaA' 8aq.

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [6:4:3:2:1]. Formed by oxidising the corresponding $C_6HMe_4.CO.CH_3$ with $KMnO_4$ (Claus a. Foecking, *B.* 20, 3103). Yellow liquid, not solidified at 0°.

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [6:5:3:2:1]. [109°] (C. a. F.); [112°] (G.). Formed by oxidising the corresponding $C_6HMe_4.CO.CH_3$ with $KMnO_4$ (Claus a. Foecking, *B.* 20, 3103). Formed also by boiling its amide for several days with alcoholic potash (G.). Plates.

Amide $C_6HMe_4CONH_2$ [173°]. From duren, $ClCONH_2$, and $AlCl_3$ (Gattermann, *A.* 244, 55). Shining plates (from dilute alcohol).

Tetra-methyl-benzoic acid $C_6HMe_4CO_2H$ [179°]. From duren, $COCl_2$, and $AlCl_3$, the product being decomposed by water (Jacobsen, *B.* 22, 1223). Also from $C_6HMe_4.CO.CO_2H$ and $KMnO_4$ (Meyer a. Ador, *J.* 1879, 562). Must be identical with one of the three preceding acids.

probably with that of Gottschalk. Large plates (from dilute alcohol), v. sl. sol. cold water. Volatile with steam. May be distilled. Conc. HClAq at 210° yields durene and CO₂.—CaA', 2. Short prisms, sl. sol. hot water.—BaA', 4aq. Small plates (from hot water).

Methyl ether C₆HMe₂CO.Me. [59°]. (269° i.V.). Plates (Jacobsen, B. 22, 1223). Saponified by alcoholic potash at 210°.

Nitrile C₆HMe₂CN. [77°]. Formed by distilling tetra-methyl-benzoic acid with PbCy₂ (Jacobsen, B. 22, 1224). Needles, v. e. sol. alcohol. Split up by HCl at 215° into durene and CO₂. A crystalline nitrile C₆H(CH₃)₂CN [69°], (260°), probably identical with the last is formed by the isomeric change of the carbamine derived from duridine (g. v.) by distillation. It is very stable towards HCl, by which it is not saponified to the acid, but at 250° it decomposes with formation of tetra-methyl-benzene (Hofmann, B. 17, 1914).

Amide C₆HMe₂CONH₂. [173°]. Formed by passing gaseous cyanic acid and HCl into durene containing AlCl₃ at 100° (Gattermann a. Rossolym, B. 23, 1199). It is probably the amide of the acid [179°], but has not been fully examined.

Penta-methyl-benzoic acid C₆Me₅CO₂H. [210-5°]. Formed from penta-methyl-benzene, COCl₂, and AlCl₃ at 0°; after a fortnight the product is exposed to moist air and then treated with water (Jacobsen, B. 23, 1230). Needles (from water) or prisms (from 70 p.c. alcohol); v. sl. sol. cold, sl. sol. hot water, v. e. sol. hot alcohol. Volatile with steam. May be distilled. With H₂SO₄ it yields C₆Me₅ and c-durene (prehnitene). HNO₃ forms di-nitro-c-durene. Fuming HClAq at 200° yields CO₂ and penta-methyl-benzene.—CaA', 2. Prisms; m. sol. water.—BaA', 2aq. Plates; sol. hot water.

Methyl ether MeA'. [67-5°]. (300° i.V.). Plates; v. sol. alcohol.

Amide C₆Me₅CONH₂. [206°]. From C₆HMe₅, chloro-formamide, and AlCl₃. Plates; sl. sol. hot, v. sl. sol. cold water.

Nitrile C₆(CH₃)₅CN. [170°] (J.); [168°] (H.). (292°) (H.); (295°) (J.). Formed from the carbamine C₆Me₅NC by intra-molecular transformation by heating it a few degrees above its melting-point (Hofmann, B. 18, 1825). Large white needles; sol. alcohol and ether, insol. water. It is remarkably stable, and could not be saponified by treatment with acids or alkalis. By heating with HI at 220°-230° it yields penta-methyl-benzene, NH₃, and CO₂. Conc. HClAq at 215° also yields C₆HMe₅.

METHYL-BENZOIC ALDEHYDE v. TOLUIC ALDEHYDE.

Di-methyl-benzoic aldehyde C₆H₂Me₂CHO [4:2:1]. *m-Xylobenzaldehyde*. *Xylylic aldehyde*. [-8°]. (216°). Formed by oxidising di-methyl-benzyl alcohol with K₂Cr₂O₇ and H₂SO₄ (Hinrichsen, B. 21, 8085; 22, 121). Separated by K₂CO₃. Colourless oil, volatile with steam. HNO₃ oxidises it to di-methyl-benzoic acid [126°].

Di-methyl-benzoic aldehyde C₆H₂Me₂CHO [5:3:1]. (221°). Formed from mesitylene by treatment in O₂ with CrO₂Cl₂, followed by water (Etard, C. R. 97, 909). The yield is almost the theoretical quantity. Yields mesitylene acid on oxidation.

Tri-methyl-benzoic aldehyde. *Phenyl hydraside* Me₃C₆H₂CH=N.NHPH. [120°]. Formed by the action of tri-methyl-benzoic aldehyde on a solution of phenyl-hydrazine in dilute HOAc (Rudolph, A. 218, 100). Colourless needles, very sensitive to light; v. sol. ether, hot alcohol, and petroleum ether.

DI-METHYL-BENZOIN C₆H₂O₂. i.s. [4:1] C₆H₂Me₂CO.CH(OH).C₆H₂Me₂[1:4]. [89°]. *p-Toluoïn*. Prepared by boiling 10 pts. of *p*-toluic aldehyde (from *p*-xylene) with 2 pts. of KCy and 30 pts. of 50 p.c. alcohol, and shaking the mass, after cooling, till the yellow product separates (Stierlin, B. 22, 380; cf. Grimaux a. Lauth, B. 7, 233). Pale-yellow prisms (from dilute alcohol); sl. sol. hot water, v. sol. alcohol, ether, and benzene. Fuming H₂SO₄ gives a beautiful green colour.

Acetyl^o derivative C₆H₂AcO₂. [100°]. White crystals; v. sol. alcohol and ether.

Benzoyl derivative C₆H₂BzO₂. [119°]. White crystals; v. sol. alcohol and ether.

METHYL-BENZONITRILE v. Nitrile of TOLUIC ACID.

Di-methyl-benzonitrile v. Nitrile of Di-methyl-benzoic acid.

METHYL-BENZOPHENONE v. PHENYL TOLYL KETONE.

Di-methyl-benzophenone v. PHENYL XYLIL KETONE and Di-TOLYL-KETONE.

TRI-METHYL-BENZOQUINONE CARBOXYLIC ACID v. ψ-CUMOQUINONE CARBOXYLIC ACID.

METHYL-BENZOYL-ACETIC ACID v. α-BENZOYL-PROPIONIC ACID.

Di-methyl-benzoyl-acetic acid [5:2:1] C₆H₂Me₂CO.CH₂CO₂H. *Xylyl methyl ketone carboxylic acid*. [132°]. Formed, together with di-methyl-benzoic acid, by oxidising xylyl ethyl ketone with very dilute KMnO₄ (Claus a. Fickert, B. 19, 3183). Needles; sl. sol. water, v. sol. alcohol and ether.—NaA' aq: crusts; v. sol. water.—CaA', 2½aq: needles; sl. sol. cold water.—BaA', 4aq: prisms; sl. sol. cold water.—AgA'.

TETRA-METHYL-BENZOYL-BENZOIC ACID C₆HMe₄CO.C₆H₂CO₂H [2:1]. *Duroyl-benzoic acid*. [c.260°]. Formed by heating phthalic anhydride with durene in presence of AlCl₃ (Friedel a. Crafts, A. Ch. [6] 14, 454; C. R. 92, 833). Insol. water, v. sol. alcohol, ether, and benzene. May be crystallised from HOAc. The Pb, Cu, and Ag salts are insol. water.—*KA': minute needles; v. sol. cold water.—*NaA'; v. sl. sol. alcohol.—*NH₄A': needles.—BaA' aq: groups of needles; v. sl. sol. water.—CaA' aq: needles; v. sl. sol. water.

METHYL-BENZOYL-ETHYL-HYDROXYLAMINE v. HYDROXYLAMINE DERIVATIVES.

TRI-METHYL-BENZOYL-PROPIONIC ACID v. ψ-CUMYL-ETHYL-KETONE-CARBOXYLIC ACID.

METHYL-DIBENZYL v. PHENYL-TOLYLETHANE.

METHYL-BENZYL-ACETIC ACID v. PHENYL-ISO-BUTYRIC ACID.

DI-METHYL-BENZYL ALCOHOL C₆H₂O i.s. [4:2:1] C₆H₂Me₂CH₂OH. *Xylyl alcohol*. [22°]. (232°). Formed by adding KNO₃ to a solution of dimethyl-benzyl-amine sulphate (Hinrichsen, B. 21, 8085). Colourless liquid, with aromatic odour, volatile with steam. Oxidised by chromic acid mixture to di-methyl-benzoic aldehyde.

Acetyl derivative C_6H_5OAc . (230°-234°).

Benzoyl derivative C_6H_5OBz . (333°). Yellow oil (Hinrichsen, *B.* 22, 123).

Penta-methyl-benzyl alcohol $C_5H_{12}O$ i.e. $C_6Me_5CH_2OH$. **Methylalcohol**. [160-5°]. Obtained by saponifying its acetyl derivative with alcoholic potash (Jacobsen, *B.* 22, 1217). Di-metric prisms, insol. water, v. sol. alcohol.

Acetyl derivative $C_6Me_5CH_2OAc$. [85°]. (310°). Obtained by the action of KOAc and HOAc on the chloride $C_6Me_5CH_2Cl$, which is got by heating hexamethyl-benzene with PCl_5 at 140° (Jacobsen). Plates or prisms (from alcohol); v. sol. ether, m. sol. alcohol at 0°, insol. water.

o-METHYL-BENZYL-AMINE

[2:1] $C_6H_4MeCH_2NH_2$. *o-Tolyl-methyl-amine*. **Xylylamine**. (202°). Formed by heating methyl-benzyl-phthalimide (derived from ω -bromo-*o*-xylene) with conc. HClAq in sealed tubes at 209° (Strassmann, *B.* 21, 577). Liquid, which absorbs moisture and CO_2 from the air.— $B'_2H_2PtCl_6$: yellow needles.— $B'HCl$: needles (from alcohol).—Picrate $B'C_6H_4N_2O_7$: long yellow needles, decomposing above 170°.

Acetyl derivative $C_6H_4MeCH_2NHAc$. [69°]. Formed by heating the hydrochloride with NaOAc and AcO. Crystallises from alcohol.

m-Methyl-benzyl-amine

[3:1] $C_6H_4MeCH_2NH_2$. Formed by heating ω -bromo-*m*-xylene with potassium phthalimide, and decomposing the product with conc. HClAq at 190° (Brömme, *B.* 21, 2700). Colourless liquid, miscible with alcohol and ether. Absorbs CO_2 from the air.— $B'HCl$: needles. $B'_2H_2PtCl_6$. [212°]. Golden plates.—Sulphate [218°].— $B'_2H_2C_2O_4$. [172°]. Plates, v. sol. water.—Picrate [156°].

Acetyl derivative $C_6H_4MeCH_2NHAc$. (235°-240°). Oil.

Benzoyl derivative $C_6H_4MeCH_2NHBz$. [69°]. White plates (from alcohol), v. sol. chloroform, HOAc, and benzene.

p-Methyl-benzyl-amine

[4:1] $C_6H_4MeCH_2NH_2$. Formed by treating an alcoholic solution of the amide of thio-*p*-toluic acid with zinc and HClAq (Palerno *A.* Spica, *B.* 8, 441).

m-(?) **Methyl-benzyl-amine** $C_6H_4MeCH_2NH_2$. **Xylylamine**. (196°). Formed, together with di-methyl-di-benzyl-amine and tri-methyl-tri-benzyl-amine by heating ω -chloro-*xylene* with alcoholic NH_3 at 116° (Pieper, *A.* 151, 129). Oil, smelling like herring-brine. Is either the *m*-compound or a mixture. Lighter than water. Absorbs CO_2 from the air.— $B'HCl$. [185°]. Needles; v. sol. water and alcohol.— $B'_2H_2PtCl_6$.

Di-m-(?) **methyl-di-benzyl-amine** $C_6H_4Me_2N$ i.e. $(C_6H_4MeCH_2)_2NH$. Formed as above (Pieper). Oil smelling like herring-brine. Lighter than water. Decomposes above 210°.— $B'HCl$. [198°]. Needles; sl. sol. cold water, v. sol. hot water and alcohol.— $B'HBr$. [196°].

Tri-m-(?) **methyl-tri-benzyl-amine** $C_6H_4Me_3N$ i.e. $(C_6H_4MeCH_2)_3N$. Formed as above (Pieper). Oil; sl. sol. alcohol. Cannot be distilled. With bromine water it yields $(C_6H_4MeCH_2)_3NH$ and C_6H_4MeCHO .— $B'HCl$. [212°] (P.); [204°] (Jannasch, *A.* 142, 808). Needles; sl. sol. cold alcohol, insol. water and ether. Heated in a

current of dry HCl it yields $(C_6H_4MeCH_2)_3NH$ and $C_6H_4MeCH_2Cl$.— $B'HNO_3$. [122°] (J.).

Di-methyl-benzyl-amine $C_6H_4Me_2N$ i.e.

[4:2:1] $C_6H_4Me_2CH_2NH_2$. (219°). **Xylyl-methyl-amine**. **Xylobenzyl-amine**. Formed by reducing with sodium the nitrile of the corresponding di-methyl-benzoic acid dissolved in alcohol (Hinrichsen, *B.* 21, 3083; 22, 122). Liquid, sl. sol. water, v. sol. alcohol and ether. Readily absorbs CO_2 and moisture from the air. Nitrous acid converts it into the corresponding alcohol.— $B'HCl$. [210°]. Needles or plates.— $B'_2H_2PtCl_6$. [223°].— $B'_2H_2HgCl_2$. [205°].—Nitrate [158°].—Sulphate [254°].—Picrate [223°].— $B'CdI_2$.— $B'_2H_2CdI_2$.

Benzoyl derivative $C_6H_4Me_2BzN$. [98°].

Needles, v. sl. sol. water, v. c. sol. alcohol and benzene.

Di-methyl-benzyl-amine v. BENZYL-DI-METHYL-AMINE.

METHYL-BENZYL-ANILINE

$C_6H_5NMeCH_2Ph$. (306°) (N.); (above 360°) (S.). From methyl-aniline and benzyl chloride (Noelting, *J.* 1883, 702; Stebbins, *A. C. J.* 7, 42). Pale-yellow oil.

p-METHYL-BENZYL-BENZOIC ACID

$C_6H_4O_2$ i.e. [4:1] $C_6H_4MeCH_2C_6H_4CO_2H$. [131°]. Formed from $C_6H_4MeCO_2C_6H_4CO_2H$ by reducing with zinc-dust and ammonia, filtering, diluting with water, adding HCl, dissolving the pp. in NH_4Cl , and re-ppg. with acid (Gresly, *A.* 234, 235). Long needles (from alcohol); v. sol. alcohol, HOAc, and benzene, almost insol. water.— BaA' : plates, v. sol. water.

Di-methyl-benzyl-benzoic acid $C_6H_4Me_2O_2$ i.e. [4:2:1] $C_6H_4Me_2CH_2C_6H_4CO_2H$ [1:2]. [158°]. Obtained by reducing $C_6H_4Me_2CO_2C_6H_4CO_2H$ with zinc-dust and ammonia (Gresly, *A.* 234, 237). Small needles (from alcohol).— BaA' aq. Plates (from dilute alcohol), sl. sol. water.

METHYL-BENZYL BROMIDE v. ω -BROMO-XYLENE.

DI-METHYL-BENZYL-CARBAMIC ETHER

$C_6H_4NO_2$ i.e. [6:4:2:1] $C_6H_4Me_2NH.CO_2Et$. **Mesityl-carbamie ether**. [62°]. From mesidine and $ClCO_2Et$ (Eisenberg, *B.* 15, 1016). Long needles (from water). Volatile with steam.

METHYL-BENZYL-CARBINOL v. PHENYL-ISO-PROPYL ALCOHOL.

PENTA-METHYL-BENZYL CHLORIDE

$C_6Me_5CH_2Cl$. [99°]. (c. 285°). Formed by heating C_6Me_5 (40 g.) with PCl_5 (50 g.) at 140° (Jacobsen, *B.* 22, 1217). Plates (from alcohol-ether); v. c. sol. ether, sl. sol. alcohol.

TRI-METHYL-BENZYL CYANATE

[6:4:2:1] $C_6H_4Me_3N.CO$. (219°). From tri-methyl-benzyl-carbamie ether and P_2O_5 (Eisenberg, *B.* 15, 1017). Pungent liquid.

METHYL-BENZYL-GLYOXIM v. BENZYL-METHYL-GLYOXIM.

DI- ω -METHYL-DI-BENZYLIDENE-ETHYLENE-DIAMINE $C_6H_4Me_2N_2$ i.e. $C_6H_4(N:CM_2O_2H)_2$

[c. 104°]. Formed by heating ethylene-diamine (1 mol.) with acetophenone (2 mols.) to 120°. White needles. V. sol. alcohol and benzene, sl. sol. ether. It is readily decomposed into its constituents, especially by acids (Mason, *B.* 20, 273).

METHYL BENZYL KETONE v. BENZYL-METHYL-KETONE.

Methyl benzyl diketone $C_9H_{10}O_2$, i.e. $CH_3.CO.CO.CH_2.C_6H_5$. (176°). S.G. $\frac{1}{4}$ 1.0721. This ketone is formed by distilling its monoxim $CH_3.CO.C(OH).CH_2.C_6H_5$ with $FeCl_3$ and dilute HCl (H. Müller a. Pechmann, B. 22, 2133). Thick yellow oil, smelling like honey.

Di-phenyl-dihydrazide
 $CH_3.C(N_2HPh).C(N_2HPh).CH_2.C_6H_5$. [173°]. Almost colourless flat silky needles.

Mono-oxim $CH_3.CO.C(OH).CH_2.C_6H_5$. **Isonitroso-benzyl-acetone**. [81°]. Formed by the action of nitrous acid on barium benzyl-acetoacetate (Ceresole, B. 15, 1876, 3072; 16, 836). Needles, insol. ligroin. May be sublimed. Dissolves in aqueous alkalis forming yellow solutions. With $NaOEt$ and benzyl chloride it gives $CH_3.CO.C(NOAc).Ph.CH_2.C_6H_5$, a thick yellow oil, volatile with steam.

Di-oxim $CH_3.C(OH).C(OH).CH_2.C_6H_5$. **Methylbenzylacetoximic acid**. [181°]. Formed by adding an alcoholic solution of hydroxylamine hydrochloride to an alcoholic solution of the mono-oxim (Schranm, B. 16, 181, 2186). Small needles. With Ac_2O it yields a di-acetyl derivative $CH_3.C(NOAc).C(NOAc).CH_2.C_6H_5$ [80°].

METHYL-BENZYL-MALONIC ACID v. BENZYL-METHYL-MALONIC ACID.

o-METHYL-BENZYL-PHTHALAMIC ACID $C_9H_9NO_4$, i.e.

[1:2] $C_6H_4.Me.CH_2.NH.CO.C_6H_4.CO_2H$ [2:1]. **o-Xylyl-phthalamic acid**. [156°]. Formed by boiling o-methyl-benzyl-phthalimide with aqueous $NaOH$ and ppg. the solution with HCl (Strassmann, B. 21, 576). Slender needles.— AgA' .

m-Methyl-benzyl-phthalamic acid
[1:8] $C_6H_4.Me.CH_2.NH.CO.C_6H_4.CO_2H$ [2:1]. [131°]. Formed in like manner from m-methyl-benzyl-phthalimide (Brömme, B. 21, 2700). Slender needles (from hot alcohol).— AgA' : v. sol. boiling water.

o-METHYL-BENZYL-PHTHALIMIDE

[1:25] $C_6H_4.Me.CH_2.N<\overset{CO}{CO}>C_6H_4$. [149°]. Obtained by heating ω -bromo-o-xylene with potassium phthalimide at 200°; the yield being 76 p.c. of the theoretical amount (Strassmann, B. 21, 576). White hexagonal crystals (from alcohol), insol. water. With conc. $HClAq$ at 200° it forms methylbenzyl-amine (202°). Aqueous $NaOH$ converts it into o-methyl-benzyl-phthalamic acid.

m-Methyl-benzyl-phthalimide

[1:8] $C_6H_4.Me.CH_2.N<\overset{CO}{CO}>C_6H_4$. **m-Xylyl-phthalimide**. [118°]. Formed in like manner by heating ω -bromo-m-xylene with potassium phthalimide at 190° (Brömme, B. 21, 2700). Slender hexagonal needles (from hot alcohol), v. sol. ether, chloroform, and alkalis.

METHYL-BENZYL-PIPERIDINE v. BENZYL-METHYL-PIPERIDINE.

METHYL BENZYL SULPHIDE $C_9H_{10}S$, i.e. $CH_3.S.CH_2.C_6H_5$. (195°–198°). Formed by heating benzyl chloride with $Pb(SMe)_2$ at 100° (Obermeyer, B. 20, 2926).

o-Methyl-benzyl thiocarbimide C_9H_9NS , i.e. [2:1] $C_6H_4.Me.CH_2.N:CS$. **o-Xylyl thiocarbimide**. (256°). Formed by boiling an ethereal solution of o-methylbenzyl-amine with CS_2 and $HgCl_2$

(Strassmann, B. 21, 678). Oil, smelling strongly like horse-radish.

Di-methyl-benzyl thiocarbimide $C_{10}H_{11}NS$, i.e. [4:2:1] $C_6H_4.Me_2.CH_2.N:CS$. **Xylobenzyl mustard oil**. Formed by heating the corresponding urea ($C_6H_4.Me_2.CH_2.NH.CO$ with syrupy phosphoric acid (Hinrichsen, B. 22, 123).

METHYL-BENZYL-THIO-UREA

$CH_3.NH.CS.NH.CH_2.C_6H_5$. [74°]. Formed by exposing an alcoholic solution of benzylamine mixed with methyl thiocarbimide for some days to the air (Dixon, C. J. 55, 619). White octahedra, v. sol. hot benzene and hot alcohol, m. sol. ether. Gives a black pp. with ammoniacal $AgNO_3$, but the aqueous or alcoholic solution is not desulphurised by prolonged boiling with alkaline lead tartrate.

Methyl-di-benzyl- ψ -thio-urea v. DI-BENZYL-METHYL- ψ -THIO-UREA.

o-Methyl-benzyl-thio-urea $C_9H_9N_2S$, i.e. [2:1] $C_6H_4.Me.CH_2.NH.CS.NH_2$. **o-Xylyl thio-urea**. [167°]. Formed by evaporating a solution of potassium sulphocyanide and o-methyl-benzylamine hydrochloride, and heating the residue to 140° (Strassmann, B. 21, 578). White needles (from water), m. sol. hot water. Turns red in air.

m-Methyl-benzyl-thio-urea

[3:1] $C_6H_4.Me.CH_2.NH.CS.NH_2$. [112°]. Prepared in the same way as the preceding body, using [3:1] $C_6H_4.Me.CH_2.NH_2$ (Brömme, B. 21, 2700).

Di-m-methyl-di-benzyl-thio-urea $C_{11}H_{13}N_2S$, i.e. ($C_6H_4.Me.CH_2.NH$). CS . [97°]. Prepared by boiling m-methylbenzyl-amine with alcoholic CS_2 (B.). Needles; insol. water, acids, and alkalis.

Tetra-methyl-di-benzyl-thio-urea $C_{13}H_{17}N_2S$, i.e. ($C_6H_4.Me_2.CH_2.NH$). CS .

Dixylobenzylsulphourea. [177°]. From (4, 2, 1)-di-methylbenzyl-amine and alcoholic CS_2 (Hinrichsen, B. 22, 123). Glittering needles (from hot alcohol).

o-METHYL-BENZYL-UREA $C_9H_9N_2O$, i.e. [2:1] $C_6H_4.Me.CH_2.NH.CO.NH_2$. **o-Xylyl-urea**. [173°]. Formed from o-methylbenzyl-amine sulphate and potassium cyanate (Strassmann, B. 21, 578). Radiating moss-like crystals (from alcohol), insol. water.

m-Methyl-benzyl-urea

[3:1] $C_6H_4.Me.CH_2.NH.CO.NH_2$. [148°]. Long needles from alcohol (Brömme, B. 21, 2700).

Di-m-methyl-di-benzyl-urea

($C_6H_4.Me.CH_2.NH$). CO . [137°]. Formed from m-methylbenzyl-amine and $COCl_2$ in ethereal solution (B.). Slender needles (from alcohol or ether).

Di-methyl-benzyl-urea $C_{11}H_{13}N_2O$, i.e.

[4:2:1] $C_6H_4.Me_2.CH_2.NH.CO.NH_2$. **m-Xylobenzyl-urea**. [184.5°]. Formed by mixing concentrated solutions of (4, 2, 1)-di-methylbenzyl-amine hydrochloride and potassium cyanate (Hinrichsen, B. 22, 122). Slender needles (from alcohol); m. sol. water from which it separates as a flocculent pp.

METHYL-BISMUTHINE v. *Bismuth methide* under BISMUTH, ORGANIC DERIVATIVES.

METHYL BORATES.

Tri-methyl-borate Me_3BO_3 . (72°) (E. a. B.); (65°) (S.). S.G. $\frac{1}{4}$.955 (E. a. B.); .940 (S.). V.D. 8.66 (E. a. B.). Prepared by heating B_2O_3 with methyl alcohol at 100° in sealed tubes, and distilling. The distillate is freed from $MeOH$ by shaking with conc. H_2SO_4 , and the upper

layer is then rectified (Schiff, *Bz.* [2] 5, 372; 6, 36). Formed also by the action of BCl_3 on dry methyl alcohol; the upper layer of the product being rectified (Ebelmen a. Bouquet, *A. Ch.* [3] 17, 59; A. 60, 251). Colourless mobile liquid, sol. alcohol and ether. Burns with a green flame (greener than that of Et_2BO_3). Decomposed by water into boric acid and MeOH .

Methyl metaborate Me_2BO_3 . A thick liquid, formed by heating Me_2BO_3 with B_2O_3 . When heated, it begins to decompose at 160° giving off Me_2BO_3 , and at 250° there remains a mass of the composition MeB_2O_5 , which becomes vitreous on cooling.

An acid methyl borate $\text{Me}_2\text{B}_2\text{O}_5$ was described by Ebelmen (*A. Ch.* [3] 16, 137) as obtained by treating B_2O_3 with dry MeOH , and as being a vitreous mass, readily decomposed by water into boric acid and MeOH . It was probably a mixture of Me_2BO_3 and MeBO_2 .

METHYL-BORNYL-UREA v. BORNYL-METHYL-UREA.

TRI-METHYL-BRAZILIN $\text{C}_{10}\text{H}_{11}\text{Me}_3\text{O}_5 \cdot 3\text{aq}$. Formed in the preparation of tetra-methyl-brazilin (v. *infra*). Crystalline, sol. dilute alcohol. Its solution in aqueous NaOH is colourless and gives a brown pp. with FeCl_3 .

Acetyl derivative $\text{C}_{10}\text{H}_{11}\text{AcMe}_3\text{O}_5$ [197].

Tetra-methyl-brazilin $\text{C}_{10}\text{H}_{11}\text{Me}_4\text{O}_5$ [139]. Formed by the action of NaOEt and MeI on brazilin (Schall a. Dralle, *B.* 20, 3365; 21, 3009). Snow-white crystals. Bromine in HOAc forms $\text{C}_{10}\text{H}_7\text{BrMe}_4\text{O}_5$ [181] and crystalline di-bromo-tetra-methyl-brazilin dibromide $\text{C}_{10}\text{H}_5\text{Br}_2\text{Me}_4\text{O}_5$.

METHYL-BROMACETOL v. *aa*-DI-BROMO-PROPANE.

METHYL BROMIDE CH_3Br . *Bromo-methane*. Mol. w. 95. (45°). S.G. $\frac{3}{4}$ 1.7331; $\frac{25}{4}$ 1.7235 (Perkin); $\frac{3}{4}$ 1.732 (Merrill). V.D. ($\text{H} - 1$) 95. M.M. 4.644 at 15° (Perkin, *C. J.* 45, 454). H.F.p. 14.790 . H.F.v. 14.219 (Thomsen). S.V. 55.7 (Lossen, *A.* 254, 68).

Preparation.—Methyl alcohol (800 grms.) and amorphous phosphorus (133 grms.) are put into a retort. Bromine (800 grms.) is slowly run in. After some hours the retort is heated and the product condensed in a receiver surrounded by a freezing mixture. It is washed with dilute potash, dried over calcic chloride and distilled (Merrill, *J. pr.* 126, 296; cf. Pierre, *J. Ph.* [3] 13, 156; Bunsen, *A.* 46, 44).

Properties.—Colourless, mobile liquid, with burning taste and pleasant smell resembling chloroform. Burns with greenish-brown smoky flame. Miscible with alcohol, ether, chloroform, and CS_2 . Poured into cold water a white ice-like mass is formed. It is approximately $\text{CH}_3\text{Br} \cdot 20\text{aq}$. At 5° it begins to split up with evolution of methyl bromide gas.

METHYL-BROMO-ACETOACETIC ETHER v. BROMO-ACETO-ACETIC ACID.

METHYL-BROMO-ACETOL v. DI-BROMO-PROPANE.

METHYL α -BROMO-ALLYL OXIDE $\text{C}_4\text{H}_7\text{BrO}$ i.e. $\text{CH}_3\text{O} \cdot \text{CH} = \text{CH} \cdot \text{CH}_2\text{Br}$. (116°). S.G. $\frac{15}{4}$ 1.35. Formed by the action of NaOH on $\text{CH}_3\text{O} \cdot \text{CH} = \text{CH} \cdot \text{CH}_2\text{Br}$ (Henry, *B.* 5, 455).

METHYL BROMO - ALLYL SULPHIDE $\text{C}_4\text{H}_7\text{BrS}$ i.e. $\text{CH}_3 \cdot \text{S} \cdot \text{CH} = \text{CH} \cdot \text{CH}_2\text{Br}$. Formed by heating $\text{Pb}(\text{SMe})_2$ with *s*-tri-bromo-propane in

etheral solution at 150° (Obermeyer, *B.* 20, 2925). Decomposes at 120° – 130° . Combines with Br (1 mol.).

METHYL-BROMO-AMINE v. METHYLAMINE.

METHYL-DI-BROMO-ANTHRACENE v. DI-BROMO-METHYL-ANTHRACENE.

METHYL-DI-BROMO-ATROLACTIC ACID v. DI-BROMO-OXY-TOLYL-PROPIONIC ACID.

METHYL BROMO - BUTYL KETONE v. ACETYL-BUTYL BROMIDE.

TRI - METHYL - BROMO - ETHYL - AMMONIUM BROMIDE v. TRIMETHYLAMINE bromo-ethyl-bromide.

METHYL-BROMO-ISATIN v. Methyl derivative of Bromo-Isatin, p. 71.

METHYL-BROMO-ISATOID v. Bromo-methyl-isatoïd, p. 71.

METHYL BROMOPROPYL KETONE

$\text{CH}_3\text{CO} \cdot \text{CH}_2 \cdot \text{CH} \cdot \text{CH}_2\text{Br}$. *Acetyl-propyl bromide*. (118°) at 90 mm. (P.); (106°) at 60 mm. (L.). Formed by treating acetyl-propyl alcohol (*q. v.*) with a saturated aqueous solution of HBr (Colman a. Perkin, jun., *C. J.* 55, 357; Lipp, *B.* 22, 1196). Colourless mobile liquid with penetrating odour. Turns brown in light. Sl. sol. cold water, quickly decomposed by hot water, dissolving as acetyl-propyl alcohol. Forms a crystalline compound with NaHSO_4 . NaOEt and KOH act on it, forming a light etheral oil $\text{C}_5\text{H}_8\text{O}$ (113°), probably methylene-furfurane tetrahydride.

METHYL-BROMO-STYRENE v. BROMO-TOLYL-ETHYLENE.

METHYL-BRUCINE v. Methyl-compounds of BRUCINE, vol. i. p. 637.

METHYL - BUTENYL TRICARBOXYLIC ACID v. PENTANE TRICARBOXYLIC ACID.

METHYL BUTENYL KETONE v. ALLYL-ACETONE.

METHYL ISOBUTYL ACETAL v. ALDEHYDE.

METHYL-BUTYL-ACETIC ACID v. HEPTOIC ACID.

Methyl-di-butyl-acetic acid v. HENDECOIC ACID.

METHYL-BUTYL-ACETYLENE v. HEPTIN-ENE.

METHYL-ISOBUTYL-ANILINE $\text{C}_{11}\text{H}_{11}\text{N}$ i.e. $\text{C}_6\text{H}_5\text{NMe} \cdot \text{CH}_2\text{Pr}$. (235°) (Noelting, *J.* 1853, 702).

METHYL - ISOBUTYL - BENZENE v. ISO-BUTYL-TOLUENE.

METHYL - BUTYL - CARBINOL v. HEXYL ALCOHOL.

Di-methyl-butyl-carbinol v. HEPTYL ALCOHOL.

METHYL ISOBUTYL CARBONATE $\text{C}_5\text{H}_{10}\text{O}_2$ i.e. $\text{CH}_3\text{O} \cdot \text{CO} \cdot \text{OC} \cdot \text{H}_2$. (143.6° cor.). S.G. $\frac{21}{4}$ 0.95 (Röse, *A.* 205, 230).

DI - METHYL - BUTYLENE - DIKETONE

$\text{C}_8\text{H}_{14}\text{O}_2$ i.e. $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH} = \text{CH} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CH}_3$. *Di-acetyl-butane*. [44°]. Obtained by heating its dicarboxylic ether with NaOMe in MeOH (Marshall a. Perkin, jun., *C. J.* 57, 241). Crystalline mass, sl. sol. water, v. sol. other menstrua. Combines with NaHSO_4 . Reacts with phenylhydrazine and with hydroxylamine. Boiling alcoholic potash condenses it forming methyl-penta-methenyl trihydride methyl ketone $\text{CH}_3 \cdot \text{C} \begin{smallmatrix} \diagup \text{O}(\text{CO} \cdot \text{CH}_3) \\ \diagdown \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} > \text{CH}_3$.

DI - METHYL - BUTYLENE - DIKETONE CARBOXYLIC ETHER $\text{C}_{10}\text{H}_{16}\text{O}_4$ i.e. $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH} = \text{CH} \cdot \text{CH}_2 \cdot \text{CH}(\text{CO} \cdot \text{Et}) \cdot \text{CO} \cdot \text{CH}_3$. *aa*-

saturated solution of NaHSO_4 on mesityl-oxide. It is easily soluble in water and alcohol, melts at 95° , is not attacked by Na_2CO_3 , but by NaOH it gives mesityl-oxide (Pinner, *D.* 15, 592).

METHYL BUTYL KETOXIM v. Oxim of METHYL BUTYL KETONE.

METHYL *n*-BUTYL OXIDE $\text{C}_5\text{H}_{12}\text{O}$ *i.e.* $\text{CH}_3\cdot\text{O}\cdot\text{C}_4\text{H}_9$. (70-3°). S.G. $\frac{8}{8}$ 7635. S.V. 127-2. C.E. (0°-10°) 00125 (Dobroiner, *A.* 243, 8).

Methyl isobutyl oxide $\text{CH}_3\cdot\text{O}\cdot\text{CH}_2\text{Pr}$. (60°). One of the products of the action of NaOCH_2Pr on methylene iodide or iodoform (Gorboff, *J. pr.* [2] 41, 238, 254). Oil. Conc. HIAq yields MeI and isobutyl iodide.

METHYL-ISOBUTYL-PHENOL $\text{C}_{11}\text{H}_{10}\text{O}$ *i.e.* $\text{C}_6\text{H}_5(\text{CH}_3)(\text{C}_4\text{H}_9)\cdot\text{OH}$ [1:3:6]. (236°). *Isobutyl-o-cresol*. Formed by the action of nitrous acid on methyl-isobutyl-phenyl-amine (Effront, *B.* 17, 2324). Oil. V. sol. alcohol and ether, nearly insol. water.

Isomeric v. Methyl ether of ISOBUTYL-PHENOL.

METHYL-ISOBUTYL-PHENYL-AMINE $\text{C}_6\text{H}_5(\text{CH}_3)(\text{C}_4\text{H}_9)\text{NH}_2$ [1:3:6]. *Isobutyl-tolyl-amine* or *toluisobutylamine*. (243°). Formed by heating *o*-toluidine hydrochloride with isobutyl alcohol at 200° - 300° (Effront, *B.* 17, 2317). Colourless liquid. Volatile with steam. Miscible with alcohol and ether, nearly insol. water.

Salts.— B^+HCl . Long thin needles, sl. sol. cold water, v. sol. hot water.— B^+HBr : long soluble needles.— $\text{B}^+\text{H}_2\text{SO}_4$: needles, sl. sol. cold water.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$: silvery needles, insol. ether.

Formyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NH}(\text{COH})$. [105°]. Colourless tablets, v. sol. alcohol and ether, nearly insol. cold water.

Acetyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NHAc}$. [162°]. Colourless plates, sparingly sol. hot water, easily in alcohol.

Benzoyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NHBz}$. [168°]. Small white needles, insol. cold water, v. sl. sol. hot.

METHYL-ISOBUTYL-PHENYL-AMINE $\text{C}_6\text{H}_5(\text{CH}_3)(\text{C}_4\text{H}_9)\text{NH}_2$ [1:5:6]. (244°). Formed by heating *o*-toluidine with isobutyl alcohol and ZnCl_2 at 270° - 280° (Effront, *B.* 17, 2339). Colourless liquid. Volatile with steam.

Salts.— B^+HCl . Plates.— $\text{B}^+\text{H}_2\text{SO}_4$: plates.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$: easily sol. ether.

Formyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NH}(\text{CHO})$. [105°]. White plates, v. sol. alcohol and ether, nearly insol. water.

Acetyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NHAc}$. [141°]. Long silky needles.

Benzoyl derivative $\text{C}_{11}\text{H}_{11}\cdot\text{NHBz}$. [142°]. Silvery plates.

METHYL-ISOBUTYL-PHENYL-DI-METHYL-AMINE $\text{C}_6\text{H}_5(\text{CH}_3)(\text{C}_4\text{H}_9)\text{NMe}_2$ [1:3:6]. *Dimethyl-toluisobutylamine*. (250°). Colourless liquid. Formed by methylation of methyl-isobutyl-phenyl-amine.— $\text{B}^+\text{H}_2\text{Cl}\cdot\text{PtCl}_4$ (Effront, *B.* 17, 2339).

DI-METHYL-DI-BUTYL-DI-PHENYL-THIO-UREA v. DI-BUTYL-DI-TOLYL-THIOUREA.

METHYL-BUTYL-PINACONE v. DI-OXY-DODECANE.

DI-METHYL-DI-ISOBUTYL-PYRAZINE $\text{C}_{11}\text{H}_{14}\text{N}_2$ *i.e.* $\text{N} \langle \text{CMe}:\text{C}(\text{C}_4\text{H}_9) \rangle \text{N}$. *Di-isobutyl-ketone*. (243°). Formed by reducing the oxim of methyl isobutyl diketone $\text{Me}\cdot\text{CO}\cdot\text{C}(\text{NOH})\cdot\text{C}_4\text{H}_9$

with tin and HCl (Lang, *B.* 18, 1864; Oeconomides, *B.* 19, 2526; Wolf, *B.* 20, 438). Yellow oil.— $\text{B}^+\text{H}\cdot\text{PtCl}_4$: orange needles.

DI-METHYL-ISOBUTYL-PYRIDINE $\text{C}_{11}\text{H}_{11}\text{N}$ *i.e.* $\text{N} \langle \text{CMe}:\text{CH} \rangle \text{C}_4\text{H}_9$. *Isobutyl-lutidine*. (210°-213°). S.G. 18 8961. Formed by distilling its carboxylic acid with lime (Engelmann, *A.* 231, 65). Oil, smelling of violets. Tastes bitter.

More soluble in cold water than in hot water.— $\text{B}^+\text{H}_2\cdot\text{PtCl}_4$. [209°]. Yellow crystalline pp.— $\text{B}^+\text{H}_2\cdot\text{Cr}_2\text{O}_7$. Yellow plates, v. sol. boiling water.—*Picrate* [115°]. Yellow needles.

Hexahydrate $\text{C}_{11}\text{H}_{11}\text{N} \cdot 6\text{H}_2\text{O}$ *i.e.* $\text{NH} \langle \text{CHMe}:\text{CH}_2 \rangle \text{CH}\cdot\text{O}\cdot\text{C}_4\text{H}_9$. *s-Isobutyl-lupetidine*. *Di-methyl-isobutyl-piperidine*. (198°) at 720 mm. Formed by reducing di-methyl-isobutyl-pyridine in alcoholic solution with sodium (Jaccckle, *A.* 246, 47). Oil. With NaNO_2 and HCl it yields a nitroso-compound.— B^+HCl . [184°]. Prisms, v. sol. water and alcohol.— B^+HBr . Prisms. The platinumchloride and chromate could not be crystallized.

DI-METHYL-ISOBUTYL-PYRIDINE DI-CARBOXYLIC ACID $\text{C}_{12}\text{H}_{11}\text{NO}_4$ *i.e.* $\text{N} \langle \text{CMe}:\text{C}(\text{CO}_2\text{H}) \rangle \text{C}_4\text{H}_9$. [273°]. Formed by boiling its diethyl ether with alcoholic, and afterwards with aqueous, potash (Engelmann, *A.* 231, 57). Long monoclinic prisms (containing 2aq). Decomposed by fusion. M. sol. cold, v. sol. hot, alcohol.— CaA'' 3aq. Small four-sided pyramids, v. sol. water.— BaA'' 5aq.— $\text{H}_2\text{A}''\cdot\text{HCl}$. M. sol. cold water.

Mono-ethyl ether HEtA'' . [135°]. Formed by boiling the di-ethyl ether with alcoholic potash. Long prisms, v. sol. water and alcohol.— $\text{Ba}(\text{EtA}'')_2$ 5aq.— $\text{HEtA}''\cdot\text{HCl}$ 2aq: thick prisms.

Di-ethyl ether $\text{Et}_2\text{A}''$. (312°-318°). Formed by passing nitrous acid gas into an alcoholic solution of its dihydride. Thick oil.— $\text{Et}_2\text{A}''\cdot\text{HCl}$: long needles, decomposed by water into HCl and $\text{Et}_2\text{A}''$.— $(\text{Et}_2\text{A}'')_2\text{H}_2\text{PtCl}_4$. [208°]. Cubes.

Dihydrate of the diethyl ether $\text{NH} \langle \text{CMe}:\text{C}(\text{CO}_2\text{H}) \rangle \text{CH}\cdot\text{C}_4\text{H}_9$. [100°]. Formed by warming acetoacetic ether with isovaleric aldehyde-ammonia in alcohol (E.). Long prisms, v. sol. alcohol, ether, and benzene.

METHYL-ISOBUTYL SULPHATE $\text{C}_5\text{H}_{12}\text{SO}_4$ *i.e.* $(\text{CH}_3)(\text{C}_4\text{H}_9)\text{SO}_4$ appears to be formed by the action of methyl alcohol on $\text{C}_4\text{H}_9\text{O}\cdot\text{SO}_3\text{Cl}$, the product of the action of isobutyl alcohol on SO_2Cl_2 (Behrend, *J. pr.* [2] 15, 34). Decomposed by water into HOMe and $\text{C}_4\text{H}_9\text{O}\cdot\text{SO}_3\cdot\text{OH}$.

DI-METHYL-ISOBUTYRYL-ACETIC ETHER *v.* *DI-ISOPROPYL-KETONE CARBOXYLIC ETHER.*

METHYL-CAFFEIC ACID v. CAFFEIC ACID. **METHYL-CAFFURIC ACID v. CAFFURIC ACID.**

METHYL CARBAMATE $\text{NH}_2\cdot\text{CO}\cdot\text{Me}$. *Methyl-urethane*. [52°] (G.); [56°] (F. a. K.). (177°). Formed from $\text{NH}_2\cdot\text{COCl}$ and excess of methyl alcohol (Gattermann, *A.* 244, 39). Formed also from $\text{C}_4\text{H}_9(\text{N}(\text{NO}_2)\cdot\text{CO}\cdot\text{Me})$, by the action of NH_3 (Franchimont a. Klobbie, *R. T. C.* 7, 848).

METHYL-CARBAMIC ACID $\text{*NHMe}\cdot\text{CO}_2\text{H}$. The methylammonium salt $\text{*NHMe}\cdot\text{CO}_2\text{NH}_2\cdot\text{Me}$ appears to be formed by pass-

ing CO₂ into dry methylamine (Wurtz, *A. Ch.* [3] 30, 450, 461).

Methyl ether NHMe.CO.Me. (158°). S.G. 1.065. Formed by treating methyl chloroformate Cl.CO.Me with an aqueous solution of methylamine (Franchimont a. Klobbie, *R. T. C.* 7, 353). Colourless liquid, with characteristic odour. With pure HNO₃ it yields a characteristic nitro-derivative.

Ethyl ether NHMe.CO₂Et. (170°). Formed from methylamine and chloro-formic ether (Schreiner, *J. pr.* [2] 21, 124). Oil, with pleasant odour. When boiled with potash or baryta it yields alcohol, methylamine, and K₂CO₃.

Chloride NHMe.COCl. [90°]. (94°). From COCl₂ and methylamine hydrochloride (Gattermann a. Schmidt, *B.* 20, 118). Decomposed on boiling.

Di-methyl-carbamic acid *NMe₂.CO₂H.

Methyl ether NMe₂.CO.Me. (131°). S.G. 1.012. Formed by treating Cl.CO.OMe with an aqueous (33 p.c.) solution of dimethylamine (Franchimont a. Klobbie, *R. T. C.* 8, 299). Colourless liquid, smelling like menthol. Pure HNO₃ forms NMe(NO₂).CO.Me.

Ethyl ether NMe₂.CO₂Et. (140°) (Schreiner, *J. pr.* [2] 21, 125); (147°) (Franchimont a. Klobbie, *R. T. C.* 3, 223). S.G. 1.073. From Cl.CO₂Et and dimethylamine. With ammonia it does not form NMe₂.CO.NH₃.

Chloride NMe₂.COCl. (165°). From dimethylamine and a solution of COCl₂ in benzene (Michler a. Escherich, *B.* 12, 1162). Liquid, with peculiar odour, v. sol. ether and CS₂. Decomposed slowly by water into HCl, dimethylamine, and CO₂.

METHYL CARBAMINE C₂H₇N i.e. CH₃.N:C. **Methyl isocyanide**. **Methyl cyanide**. **Methyl carbamate**. **Isocetonitrile**. Mol. w. 41. [-45°]. (59-6°). V.D. 1.44 (calc. 1.42). S.G. 1.756. S. 10 at 15°. Formed by the action of MeI (1 mol.) on silver cyanide (2 mols.) the product being decomposed by KOH and dried over CaCl₂ (Gautier, *C. R.* 63, 924; 65, 468, 862; 66, 1214; *A.* 152, 222; *A. Ch.* [4] 17, 203). Formed also by the action of MeI on mercuric fulminate (Calmels, *J. pr.* [2] 30, 319; *C. R.* 99, 794).

Properties.—Liquid with powerful odour, producing nausea.

Reactions.—1. **Aqueous acids** decompose it into methylamine and formic acid.—2. HOAc forms CH₃NH.CHO and Ac₂O.—3. Oxidised by HgO at 50° to methyl cyanate CH₃N.CO and a compound Me₂N₂C₂O₂(NH₂.CHO) [175°]. HgO in ethereal solution appears also to form diformamide NH(CHO)₂ or, rather, a compound Me₂N₂C₂O₂(NH(CHO)₂) [163°] (Gautier, *C. R.* 67, 804).—4. With AgCy it forms a compound MeNCaCy [80°-90°] (Meyer, *J.* 1856, 523). **Salt**.—(MeNC)₃HCl. Formed by passing HCl into an ethereal solution of methyl carbamate. Crystalline. Decomposed by water, partially reproducing methyl carbamate.—5. MeI acts in a complicated manner (Lubavine, *Bl.* [2] 45, 246; Gautier, *A. Ch.* [4] 17, 148).

Tri-methyl-carbamine. A name used by Rudneff (*Bl.* [2] 88, 297) to denote *tert*-BUTYLAMINE.

METHYL-SEMI-CARBAZIDE C₂H₇N₂O i.e. NH₂.CO.NH.NHMe. [113°]. Formed from

methyl-hydrazine acid sulphate KHO and KONO (Brüning, *A.* 253, 10). Prismatic tables; v. sol. water and EtOH; m. sol. ether.

METHYL-CARBAZOLE C₁₀H₁₁N i.e.

$\begin{matrix} C_6H_5 \\ | \\ C_6H_4 \end{matrix} > NMe.$ [87°]. Formed by heating potassium carbazole with MeI at 180° (Graebe, *A.* 202, 23). Micaceous leaflets or needles, insol. water, sol. ether. Conc. H₂SO₄ containing a little HNO₃ gives a green colour.—Piorate C₁₀H₇NC₂H₄(NO₂)₂OH. [141°]. Dark-red needles.

METHYL-CARBIMIDO-ALLYL-THIO-UREA

$SC < \begin{matrix} NC_2H_5 \\ NH \end{matrix} > C:NMe$ or C₂H₅.NH.CS.N:C.NMe. **Allyl-thio-carbamine-methyl-cyanide**. [110°]. Formed by the action of methyl iodide upon sodium carbimido-allyl-thio-urea. Crystalline. V. sol. water and alcohol. Indifferent body (Wunderlich, *B.* 19, 448).

METHYL-CARBIMIDO-ETHYL-THIO-UREA

$SC < \begin{matrix} NH \\ NH \end{matrix} > C:NMe$ or EtNH.CS.N:C.NMe. **Ethyl-thio-carbamine-methyl-cyanide**. [162°]. Formed by the action of methyl iodide upon sodium carbimido-ethyl-thio-urea (Wunderlich, *B.* 19, 448).

TRI-METHYL-CARBINOL v. *Tert*-BUTYL ALCOHOL.

METHYL CARBONATES.

Hydrogen methyl carbonate *MeHCO₃. The Ba salt, Ba(MeCO₃), appears to be the white pp. formed when CO₂ is passed into a solution of BaO in anhydrous methyl alcohol (Dumas a. Péligot, *A. Ch.* [2] 74, 6). It is insol. alcohol, but dissolves in water, the solution soon depositing BaCO₃.

Di-methyl carbonate C₂H₆O₃ i.e. (CH₃)₂CO₃. [0-5°] (Röse, *A.* 205, 231). (91°). S.G. 2.1069. H.F.p. 138,390. H.F.v. 136,360 (Thomsen, *Th.*). Formed by boiling methyl chloroformate ClCO₂Me with lead oxide (Couneler, *B.* 13, 1697). Formed also from ClCO₂Me and NaOMe (Schreiner, *J. pr.* [2] 22, 354). Oil, insol. water, sol. alcohol and ether. Converted by dry chlorine into hexa-chloro-di-methyl carbonate (q.v.).

METHYL-CARBOXYRIDIC ACID v. **METHYL-PYRIDINE CARBOXYLIC ACID**.

METHYL-CARBOSTYRIL v. **Methyl ether of CARBOSTYRIL and OXY-METHYL-QUINOLINE**.

METHYL CETYL KETONE C₁₉H₃₉O i.e. C₁₈H₃₇.CO.CH₃. [52°]. (252° at 100 mm.). Formed by distilling a mixture of barium margarate and barium acetate (Kraft, *B.* 15, 1707). Yields palmitic and acetic acids on oxidation.

METHYL-CHELIDAMIC ACID v. **CHELIDONIC ACID**.

METHYL-CHLORACETOL v. **DI-CHLORO-PROPANE**.

METHYL CHLORIDE CH₃Cl. **Chloromethane**. Mol. w. 50.5. (-23.7°) (Regnault). V.D. 1.73 (calc. 1.75). S.G. 2.27-2.915; 2.9523 (Vincent a. Delachanal, *A. Ch.* [5] 16, 429). S. 5.03 at 7°; 3.46 at 20° (Baeyer, *A.* 107, 181). S. (alcohol) 35. S. (HOAc) 40. H.F.p. 22,550. H.F.v. 21,970 (Thomsen). S.V. 50.8 (Lossen, *A.* 254, 68). **Latent heat of evaporation** 96,900 at 0° (Chappuis, *A. Ch.* [6] 15, 507).

Formation.—1. By heating a mixture of NaCl (2 pts.), wood spirit (1 pt.) and H₂SO₄ (3 pts.) and collecting the gas over water

(Dumas a. Péligot, *A. Ch.* 61, 193; *A.* 15, 17).—
2. By exposing a mixture of equal volumes of methane and chlorine to daylight (Berthelot, *A. Ch.* [3] 52, 97).

Preparation.—1. HCl is passed into MeOH (2 pts.) containing ZnCl₂ (1 pt.). The gas is passed through KOH and H₂SO₄ (Groves, *C. J.* 27, 641; *A.* 174, 378).—2. By heating trimethylamine hydrochloride at 260°, the reaction being perhaps 3NMe₃·HCl = 2NMe₃ + NH₃ + 3MeCl (Vincent, *J. Ph.* [4] 30, 132).

Properties.—Colourless gas, with ethereal odour. Burns with a bright flame, edged with green.

Reactions.—1. When passed through a red-hot tube it deposits charcoal and yields HCl, methane, ethylene, CO, and naphthalene (Perrot, *A.* 101, 875).—2. When passed over heated potash-lime it yields potassium formate, KCl, and hydrogen.—3. Not attacked by chlorine in diffused daylight, but when the mixture is exposed to direct sunlight, substitution occurs, the products being methylene chloride, chloroform, and CCl₄. The chlorination may also be effected by passing a mixture of chlorine and methylchloride over animal charcoal at 250°–350° (Damoiseau, *C. R.* 92, 42).—4. When equal volumes of methyl chloride and of an amine are submitted to a pressure of 25 atmospheres for 48 hours the following reactions occur.—(a) Ammonia forms NMe₃·Cl, NMe₃·HCl, and 2NH₃·Cl.—(b) Methylamine forms 2NMeH₂·Cl and NMe₂·Cl.—(c) Dimethylamine reacts with formation of NMe₂·H₂·Cl and NMe₂·Cl.—(d) Trimethylamine forms NMe₃·Cl (Vincent a. Chapuis, *Bl.* [2] 45, 496).

Hydrate MeCl 9aq. Formed by cooling below 0° water into which MeCl is passed. Its vapour-tension has been studied by De Forcrand a. Villard, *C. R.* 106, 1357, 1404).

METHYL-CHLORO-ALLYL CARBINOL *v.*

CHLORO-PENTENYL ALCOHOL.

DI-METHYL-CHLORO-ANILINE *v.* **CHLORO-DI-METHYL-ANILINE.**

TRI-METHYL CHLORO-AURO-PHOSPHITE Me₃PAuClO₃. [101°]. Formed by the action of pure methyl alcohol on aurous chloride and phosphorus (Lindet, *C. R.* 103, 1014). Slender colourless needles, insol. water, sol. MeOH.

METHYL CHLORO-BUTYL CARBINOL *v.* **CHLORO-HEXYL ALCOHOL.**

METHYL - CHLORO - CARBOSTYRIL *v.* **CHLORO-OXY-METHYL-QUINOLINE.**

METHYL CHLORO-ETHYL OXIDE C₃H₇ClO *i.e.* CH₃·CHCl·OMe. (72°–75°). S.G. 1.21996. Formed from aldehyde (1 vol.), methyl alcohol (1½ vols.), and dry HCl at 0° (Geuther, *A.* 225, 270).

METHYL TETRA-CHLORO-ETHYL OXIDE C₂H₂Cl₄O *i.e.* CCl₂·CHCl·O·CH₂. (178°). S.G. 1.184. Formed by the action of PCl₅ on chloral methylate (Magnanini, *G.* 16, 330). Colourless liquid.

METHYL CHLORO-FORMAMIDE *v.* **CHLORO-FORMIC ACID.**

METHYL CHLORO - PROPYL KETONE C₃H₇ClO *i.e.* CH₃·CO·CHCl·Et. (180°). Formed by heating CH₃·CO·Cl·Et·CO₂·Et with dilute HCl at 180° (Conrad, *A.* 188, 241).

Methyl tri-chloro-propyl ketone C₃H₂Cl₃O *i.e.* CH₂·CO·C₂HCl₂. (198°). Formed by oxidising

C₃H₂Cl₃·CHMe.OH with chromic acid mixture (Garzarolli-Thurnlackh, *A.* 223, 152). Heavy oil. Does not combine with NaHSO₄. Yields CO₂, acetic acid, and HCl on oxidation.

DI-METHYL-CHLORO-QUINALDINE *v.* **CHLORO-TRI-METHYL-QUINOLINE.**

METHYL-TRI-CHLORO-QUINOLINE *v.* **TRI-CHLORO-METHYL-QUINOLINE.**

METHYL DI-CHLORO-VINYL OXIDE C₃H₂Cl₂O *i.e.* CCl₂·CHCl·O·CH₃. (110°). S.G. 1.2334; ¹⁰⁰ 1.1574. Prepared by heating tri-chloro-ethylene with KOMe, being ppd. on addition of water (Denaro, *G.* 14, 117). Colourless oil, with an odour resembling that of acetal. Decomposed on exposure to air, with evolution of HCl. When heated with dilute H₂SO₄ it yields di-chloro-acetic orthaldehyde.

Methyl tri-chloro-vinyl oxide CCl₂·CCl·O·CH₃. Readily absorbs dry oxygen, forming the compound COCl·CCl(OMe), which, by the action of water, gives oxalic acid (Henry, *B.* 12, 1838).

METHYL-CHRYSOIDINE *v.* **Benzene-Azo-methyl-phenylene-diamine.**

METHYL-CINCHENIC ACID *v.* **CINCHENE.**

METHYL - CINCHONAMINE *v.* **CINCHONA BASES.**

DI-METHYL-CINCHONIC ACID *v.* **DI-METHYL-QUINOLINE CARBOXYLIC ACID.**

METHYL-CINCHONIDINE *v.* **CINCHONIDINE.**

METHYL-CINCHONINE *v.* **CINCHONINE.**

METHYL-CINNAMIC ACIDS *v.* **PHENYL-METHACRYLIC ACID AND TOLYL-ACRYLIC ACID.**

METHYL - CINNAMIC ALDEHYDE *v.* **PHENYL-METHACRYLIC ALDEHYDE.**

METHYL CINNAMYL KETONE *v.* **BENZYL-IDENE-ACETONE.**

METHYL-CINNOLINE CARBOXYLIC ACID

C₁₀H₈N₂O₂ *i.e.* C₆H₅(CO₂H) < $\begin{matrix} \text{OMe:CH} \\ \text{N=N} \end{matrix}$. [c. 230°].

Small tables or fine needles. Sol. acetic acid, al. sol. hot alcohol and hot water, insol. cold water. Dissolves both in aqueous acids and alkalis, forming easily soluble salts. Obtained, as a yellow pp., by adding NaNO₂ to a cold solution of the hydrochloride of amido-propenyl-benzoic acid C₆H₅(OMe·CH₂)(NH₂)CO₂H [1:2:4]; very probably di-azo-propenyl-benzoic acid C₆H₅(CO₂H) < $\begin{matrix} \text{CMe:CH}_2 \\ \text{N=N.OH} \end{matrix}$ is first formed, which then splits off H₂O (Widman, *B.* 17, 722).

METHYL-CITRACONIC ACID C₆H₈O₄. [100°]. A product of the dry distillation of methyl-paraconic acid (Fränkel, *A.* 255, 25). Long needles (from CHCl₃). Reduced by sodium-amalgam to ethyl-succinic acid. — CaA" aq. — BaA" 4aq. — Ag₂A'.

METHYL-COCAINE C₁₇H₁₉NO₄. [47°]. Extracted from synthetical cocaine (cf. vol. ii. p. 230), in which it occurs in very small quantity (Liebermann a. Giesel, *B.* 23, 508, 926). An oil, which crystallises after standing some hours. Ppd. by Na₂CO₃ from its salts. Very sol. ether, chloroform, benzene, and ligroin. It can be separated from ordinary cocaine by means of its nitrate. A 5.4 p.c. solution of the hydrochloride in a 2-dm. tube gave a rotation of +4.5°. By heating with water it is not so easily decomposed as ordinary cocaine. By boiling with hydriodic acid MeI is split off. By hydrochloric acid it is split

up finally into methyl alcohol, benzoic acid, and methyl ecgonine hydrochloride. This reaction is also more difficultly brought about than with ordinary cocaine. Methyl-cocaine appears to be identical with 'dextro-cocaine,' a body got by heating the methyl-ether of dextro-ecgonine with BzCl (Einhorn a. Marguardt, *B.* 23, 468).

Salts.— B^+HCl . [210°]: needles or columns forming rosettes (from hot alcohol); much less soluble than the hydrochloride of ordinary cocaine.—Sulphate: plates, v. sol. water, sl. sol. alcohol.—Nitrate: crystals, sl. sol. water.—Platino-chloride $(\text{C}_{15}\text{H}_{21}\text{NO}_2\text{HCl})_2\text{PtCl}_4$: glittering yellowish needles (from hot water).—Auro-chloride $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{HClAuCl}_4$. [148°]: needles; melts under water to a yellow oil.

METHYL-CODEINE $\text{C}_{15}\text{H}_{21}\text{NO}_2$, i.e.

$\text{C}_{15}\text{H}_{21}\text{MeNO}_2$ or $\text{C}_{17}\text{H}_{23}\text{Me}_2\text{NO}_2$. [118-5°]. $[\alpha]_D^{20} = -209'$ in a 4 p.c. solution (in 97 p.c. alcohol) at 15°. Formed by boiling codeine methyl-iodide $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeI}$ with potash, and extracting with benzene (Grimaux, *A. Ch.* [5] 27, 276; Hesse, *A.* 222, 218). Anhydrous prisms (from alcohol or ether), or hydrated crystals (containing aq) (from water). Insol. water, v. e. sol. hot alcohol, m. sol. ether. Its solution in conc. H_2SO_4 is violet, but becomes blue on heating. Boiling Ac_2O forms a compound $\text{C}_{17}\text{H}_{23}\text{O}_3$. [131°]. Its hydrochloride forms a brown solution in H_2SO_4 , which becomes violet on warming, and finally blue on exposure to the air.— B^+HCl 2aq: needles. S. 9 at 18°. V. e. sol. alcohol, sl. sol. NaCl aq.— $\text{B}^+\text{H}_2\text{PtCl}_6$ aq.

Acetyl derivative $\text{C}_{17}\text{H}_{19}\text{AcMe}_2\text{NO}_2$. [66°]. Formed by heating methyl-codeine with Ac_2O at 85°, adding aqueous NH_3 and extracting with ether (Hesse, *A.* 222, 222). Glittering tables (from ether); v. sol. alcohol and ether, sl. sol. water, insol. KOH aq. Alcoholic potash forms potassium acetate and methyl-codeine.— $(\text{C}_{17}\text{H}_{19}\text{AcMe}_2\text{NO}_2)\text{HCl}$ ½ aq: satiny plates, sl. sol. cold water.— $(\text{C}_{17}\text{H}_{19}\text{AcMe}_2\text{NO}_2)_2\text{H}_2\text{PtCl}_6$ 4aq: yellow laminae.— $(\text{C}_{17}\text{H}_{19}\text{AcMe}_2\text{NO}_2)_2\text{IINO}$ 3aq: satiny plates.— $(\text{C}_{17}\text{H}_{19}\text{AcMe}_2\text{NO}_2)_2\text{H}_2\text{SO}_4$ 8aq.

(a) *Methyl-iodide* $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeI}$ ½ aq: prisms, formed at once on dissolving methyl-codeine in a mixture of MeI and methyl alcohol (Hesse).

(b) *Methyl-iodide* $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeI}$. Slender crystals, formed by boiling the preceding with aqueous NaOH , and ppg. with KI . It is less soluble in water than its (a)-isomeride. Ag_2SO_4 forms $(\text{C}_{15}\text{H}_{21}\text{NO}_2\text{Me})_2\text{SO}_4$, crystallising in plates.

(a) *Methyl-chloride* $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeCl}$. From the (a)-iodide and AgCl . Amorphous. With platinic chloride it yields a yellow flocculent pp. of $(\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeCl})_2\text{PtCl}_6$ 8aq. With Ac_2O it yields $\text{C}_{15}\text{H}_{21}\text{AcNO}_2\text{MeCl}$ 2½ aq, which crystallises in long satiny needles, v. e. sol. alcohol, sl. sol. cold water. Its platinochloride $(\text{C}_{15}\text{H}_{21}\text{AcNO}_2\text{MeCl})_2\text{PtCl}_6$ 4aq is a yellow crystalline pp.

(b) *Methyl-chloride* $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeCl}$ ½ aq. Radiating crystalline mass, v. sol. water and alcohol. With conc. H_2SO_4 it gives a purple colour. With platinic chloride it yields an orange pp. of small needles of the platinochloride $(\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeCl})_2\text{PtCl}_6$ aq. With Ac_2O it yields amorphous $\text{C}_{15}\text{H}_{21}\text{AcNO}_2\text{MeCl}$, which forms $(\text{C}_{15}\text{H}_{21}\text{AcNO}_2\text{MeCl})_2\text{PtCl}_6$ 8aq, a yellow powder.

Methylo-hydroxide $\text{C}_{15}\text{H}_{21}\text{NO}_2\text{MeOH}$. Formed from the (b)-methyl-~~al~~phate and baryta. Colourless plates, insol. ether, v. sol. alcohol. Strongly alkaline in reaction. Conc. H_2SO_4 forms a blue solution. Gives off tri-methylamine when strongly heated.

METHYL-COLCHICINE $\text{C}_{22}\text{H}_{27}\text{NO}_4$, i.e.

$\text{C}_{15}\text{H}_{21}(\text{OMe})_2(\text{NAcMe})\text{CO}_2\text{Me}$. Occurs in the mother-liquor from which the compound of colchicine with chloroform has separated (vol. ii. p. 234). Decomposed by boiling dilute HCl into methyl chloride and methyl-colchicein $\text{C}_{15}\text{H}_{21}(\text{OMe})_2(\text{NAcMe})\text{CO}_2\text{H}$ (Johanny a. Zeisel, *M.* 9, 871).

DI-METHYL-COLCHICINIC ACID v. Di-methyl derivative of COLCHICINIC ACID.

Tri-methyl-colchicininc acid $\text{C}_{15}\text{H}_{21}\text{NO}_4$, i.e. $\text{C}_{15}\text{H}_{21}(\text{OMe})_3(\text{NHAc})\text{CO}_2\text{H}$. [150°]. Formed by the action of HCl on colchicein (*q. v.*). Forms a platinochloride $\text{B}^+\text{H}_2\text{PtCl}_6$ 2aq. On warming with acetic anhydride it yields colchicein $\text{C}_{15}\text{H}_{21}(\text{OMe})_2(\text{NHAc})\text{CO}_2\text{H}$. With MeOH it forms an addition-product $\text{C}_{22}\text{H}_{27}\text{NO}_2\text{MeOH}$. On warming with MeOH , methyl iodide, and sodium it yields 'tri-methyl-colchidimethinic acid' $\text{C}_{15}\text{H}_{21}(\text{OMe})_3(\text{NMe}_2)\text{CO}_2\text{H}$ [125°]. The methyl ether of this body forms an iodomethylate $\text{C}_{22}\text{H}_{27}\text{NO}_4\text{Iaq}$ (Johanny a. Zeisel, *M.* 9, 877).

METHYL-CONINE v. CONINE.

METHYL-COUMARIC ACID v. Methyl-derivative of COUMARIC ACID.

Di-methyl-di-coumaric acid so-called v. DI-METHYL-DI-COUMARIN.

METHYL-COUMARILIC ACID $\text{C}_{16}\text{H}_{18}\text{O}_4$, i.e.

$\text{C}_6\text{H}_5\text{C}(\text{OMe})_2\text{C}(\text{OMe})_2\text{CO}_2\text{H}$. [126°]. Formed by the action of dilute KOH upon the methyl-derivative of *exo*-bromo-coumaric acid (Perkin, *O. J.* 39, 423). Needles (from CS_2).

(b) Methyl-coumarilic acid $\text{C}_{16}\text{H}_{18}\text{O}_4$, i.e.

$\text{C}_6\text{H}_5\text{C}(\text{OMe})_2\text{C}(\text{OMe})_2\text{CO}_2\text{H}$. [180°]. Formed by saponifying its ethyl ether with alcoholic potash (Hantzsch, *B.* 19, 1290). Feathery needles (from dilute alcohol). Decomposed by heat into CO_2 and (b)-methyl-coumarone.— KA aq: needles.— NH_4A aq: needles (from water).— BaA 3aq.— AgA : minute prisms.

Ethyl ether EtA . [51°]. (200°). Formed by the action of sodium phenylate NaOC_6H_5 upon chloro-aceto-acetic ether, the resulting phenoxy-aceto-acetic ether being condensed by cold conc. H_2SO_4 (Hantzsch).

Amide $\text{C}_6\text{H}_5(\text{CH}_2)_2\text{O.CO.NH}_2$: [145°]; needles (Hantzsch, *B.* 19, 2401).

Di-methyl-coumarilic acid $\text{C}_{11}\text{H}_{10}\text{O}_4$, i.e.

$\text{C}_6\text{H}_5(\text{CH}_2)_2\text{C}(\text{CH}_3)_2\text{C}(\text{CH}_3)_2\text{CO}_2\text{H}$. Di-methyl-coumarone-*α*-carboxylic acid. [225°].

Formation.—1. By the action of hot alcoholic KOH upon bromo-di-methyl-coumarin $\text{C}(\text{CH}_3)_2\text{CBr}$

$\text{C}_6\text{H}_5(\text{CH}_2)_2\text{C}(\text{CH}_3)_2\text{C}(\text{CH}_3)_2\text{CO}$ —2. By saponification of the ethyl-ether obtained by the reaction of sodium *p*-cresol and chloro-aceto-acetic ether.

Properties.—Short prisms or tables. On heating the sodium salt with lime di-methyl-coumarone is obtained.

Ethyl ether A/Et : [55°]; (800° at 725 mm.) (Hantzsch a. Lang, *B.* 19, 1299).

Reference.—COUMARILIC ACID and OXY-METHYL-COUMARILIC ACID.

METHYL-COUMARIN *v.* Anhydride of Oxy-PIENYL-CROTONIC ACID.

m-β-Di-methyl-coumarin $C_{11}H_{10}O_2$ *i.e.*

by the action of H_2SO_4 on a mixture of acetoacetic ether and *p*-cresol (Pechmann *a.* Duisberg, *B.* 16, 2127; Pechmann *a.* Cohen, *B.* 17, 2187). Long colourless needles.

Reference.—BROMO-DI-METHYL-COUMARIN.

Di-methyl-di-coumarin $C_{11}H_{10}O_4$ *i.e.*

cin (1 mol.) and acetoacetic ether (2 mols.) in conc. H_2SO_4 ; yield 10 p.c. Microcrystalline white powder. *V.* sl. sol. boiling alcohol, nearly insol. water, ether, chloroform, benzene, &c. Dissolves in aqueous alkalis to a yellow solution, from which acids ppt. di-methyl-di-coumaric acid $C_9H_6(OH)_2(CMe:CH.CO_2H)_2$. The latter forms a white powder, sol. alcohol; at 140° it is completely reconverted into the anhydride (Hantzsch *a.* Zürcher, *B.* 20, 1328).

Tri-methyl-tri-coumarin $C_{11}H_{12}O_6$ *i.e.*

glucin (1 mol.) and acetoacetic ether (3 mols.) in conc. H_2SO_4 ; the yield is less than 10 p.c. Amorphous powder. Insol. all solvents. Dissolves in aqueous alkalis to a yellow solution, from which acids ppt. tri-methyl-tri-coumaric acid $C_9(OH)_3(CMe:CH.CO_2H)_3$, whose sodium salt is $Na_3A^{+}6aq$ (Hantzsch *a.* Zürcher, *B.* 20, 1330).

(β)-METHYL-COUMARONE C_9H_8O *i.e.*

Di-methyl-coumarone $C_{10}H_{10}O$ *i.e.*

Indifferent oil. Formed by distilling the sodium salt of di-methyl-coumarilic acid (di-methyl-coumarone-*a*-carboxylic acid with lime (Hantzsch *a.* Lang, *B.* 19, 1300).

METHYL-CREOSOL *v.* Methyl ether of CREOSOL.

METHYL CROTONIC ACIDS *v.* ANGELIC ACID and TRIGLIC ACID.

METHYL ISOCROTYL OXIDE *v.* Sec-ISOBUTENYL ALCOHOL.

METHYL-CUMARIN *v.* METHYL-COUMARIN.

METHYL-CUMAZONIC ACID $C_{12}H_{12}NO_4$

Formation.—1. By boiling (3:4:1)-amido-oxypropyl-benzoic acid with acetic anhydride. 2. By boiling acetyl-amido-oxypropyl-benzoic acid with HCl. 3. By boiling acetyl-amido-propenyl-benzoic acid with HCl. Small colourless trimetric tables. *V.* sol. alcohol, insol. water. Its N is tertiary.

Reactions.—By reduction with sodium-

amalgam it yields the acetyl derivative of amido-cuminic acid.

Salts.— $A'H.HCl$: very soluble white needles.— $(A'H.HCl)_2PtCl_4$: tables, cubes, or prisms.— $A'H.H_2SO_4$ aq: very soluble white silky needles (Widmann, *B.* 16, 2576).

METHYL-CUMENE *v.* CUMENE.

METHYL-ψ-CUMIDINE $C_{10}H_{12}N$ *i.e.* $C_6H_4(CH_3)_2NHMe$. $[44^\circ]$. (237°) . Formed by methylation of solid cumidine $[63^\circ]$.— $B'_2H_2Cl_2PtCl_4$: sparingly soluble needles (Hofmann, *B.* 15, 2896).

Di-methyl-ψ-cumidine $C_6H_4(CH_3)_2NMe_2$ (222°) . Oil. Formed by methylation of solid cumidine $[63^\circ]$.— $B'_2H_2Cl_2PtCl_4$ (Hofmann, *B.* 15, 2897).

Methylo-iodide $C_6H_4(CH_3)_2NMe_2I$. Prisms. Yields $(C_6H_4(CH_3)_2NMe_2Cl)_2PtCl_4$.

METHYL CUMYLETHYL KETONE

$C_6H_5.C_6H_4.CH_2.CO_2CH_3$. Cuminyl-acetone. $(260^\circ-265^\circ)$. Is one of the products of the action of NaOH and cuminyl chloride on acetoacetic ether (Widmann, *B.* 22, 2271). Colourless liquid, with fragrant odour. Is not acted upon by NaOBr. Oxidised by $KMnO_4$ to cuminic acid.

Oxim $C_6H_5.C_6H_4.CH_2.CO_2C(OH).CH_3$. $[57^\circ]$. Long shining prisms (from ligroin).

METHYL CUMYL KETONE

$CH_3.CO.C_6H_4.Pr$ $[14^\circ]$. (253°) . S.G. $\frac{15}{4}$.9755. Formed by the action of AcCl on cymene in presence of $AlCl_3$ (Widmann, *B.* 21, 2225).

Oxim $CH_3.C(OH).C_6H_4.Pr$. $[71^\circ]$. Four-sided tables (from petroleum-ether).

Phenyl-hydrazide

$CH_3.C(N_2HPh).C_6H_4.Pr$. $[82^\circ]$. Colourless thick six-sided tables (from petroleum-ether).

METHYL-CYANAMIDE *v.* Cyanamide in the article CYANIC ACIDS.

METHYL CYANATE *v.* CYANIC ACIDS.

METHYL-CYANETHINE *v.* CYANETHINE.

METHYL CARBIMIDE is Methyl isocyanate *v.* CYANIC ACIDS.

METHYL-CYANIC ACID *v.* CYANIC ACID.

METHYL CYANIDES *v.* ACETONITRILE and METHYL CARBAMINE.

Di-methyl di-cyanide $C_2H_2N_4$ *i.e.*

$NH.CMe.CH_2.CN$ or $NH_2.CMe:CH.CN$. $[53^\circ]$. *V.D.* 42.5. Formed by the action of dry sodium on acetonitrile dissolved in ether. Methane is evolved in the reaction, and the product is decomposed by water (Holtzwardt, *J. pr.* [2] 38, 343; 39, 210). White needles, *v.* sol. ether, alcohol, chloroform, and benzene, *m.* sol. water, *sl.* sol. petroleum ether.

Reactions.—1. Boiling water liberates ammonia forming $C_2H_2N_2O$, a body which is converted by PCl_5 into crystalline $C_2H_2N_2OCl_2$ $[175^\circ]$, which, on recrystallisation from water, becomes $C_2H_2N_2$.—2. Acetyl chloride forms a compound $(C_2H_2N_2)_2CH_2.COCl$, which on decomposition by water yields $C_2H_2N_2$, crystallising in beautiful white needles $[223^\circ]$.—3. Warm dilute (25 p.c.) HCl aq forms NH_4Cl and an oil which has the composition of cyano-acetone. It solidifies to a glassy mass, carbonises above 230° , and forms with phenyl-hydrazine a condensation product $[97^\circ]$.

Tri-methyl tri-cyanide *v.* CYANMETHINE.

METHYL-CYANO-FORMAMIDE *v.* Methyl-amide of Para-CYANOFORMIC ACID.

METHYL-CYANO-SUCCINIC ETHER

C_6H_9NO , i.e. $CO.Et.CH_2.CMeCy.CO.Et$. An oil formed by treating cyano-succinic ether with Na and MeI successively (Barthe, C. R. 108, 297).

s-Di-methyl-cyano-succinic ether $C_8H_{11}NO$, i.e. $CO.Et.CHMe.CMeCy.CO.Et$. (278°). S.G. 25 1.0577. A product of the action of alcoholic KCy on α -bromo-propionic ether (Zelinsky, B. 21, 3164). Formed also by adding α -bromo-propionic ether to cyano-propionic ether mixed with KCy (Z.).

METHYL-CYANURIC ACID v. *Cyanuric acid* in the article CYANIC ACIDS.

METHYL CUMYL KETONE $C_{12}H_{18}O$ i.e. $CH_3.CO.C_6H_4.Me.C_6H_5$. [21°]. (217°). An oil, formed by the action of $AcCl$ on cymene in presence of $AlCl_3$ (Claus, B. 19, 233).

METHYL-DAMBOSE v. BORNEITE, vol. i. p. 524.

Di-methyl-dambosé v. DAMRONITE.

METHYL-DAPHNETIN v. DAPHNETIN.

METHYL DECYL KETONE $C_{17}H_{34}O$ i.e. $CH_3.CO.C_{10}H_{21}$. [21°]. (217°). Formed by distilling a mixture of barium acetate and barium benedecate (undecylate) (Krafft, B. 15, 1708). Yields acetic and decanoic acids on oxidation.

METHYL-DESOXYBENZOLIN v. TOLYL BENZYL KETONE.

Dimethyldesoxybenzoin v. BENZYL XYLIL KETONE.

METHYL DODECYL KETONE $C_{17}H_{34}O$ i.e. $CH_3.CO.C_{12}H_{25}$. [34°]. (206° at 100 mm.). Formed by distilling barium tridecoteate ($C_{12}H_{25}O_2$)₂Ba with barium acetate (Krafft, B. 15, 1708). Yields lauric and acetic acids on oxidation.

METHYL c-DURYL KETONE $C_{12}H_{18}O$ i.e. $CH_3.CO.C_6H_4.Me$, [1:2:3:4:5]. (259°). From *c*-durene, $AcCl$, and $AlCl_3$ (Claus a. Föhlich, J. pr. [2] 88, 230). Oil.

Phenyl hydrazide. [129°]. Lamine.

Isomerides v. DURL METHYL KETONES.

METHYL-ECGONINE $C_{16}H_{17}NO$. [264°]. A product of the action of HCl on methyl-cocaine, the resulting methyl-ecgonine hydrochloride being decomposed by Ag_2O (Liebemann a. Giesel, B. 23, 510). May be crystallised from methyl alcohol containing a trace of water. Extremely sol. water, insol. absolute alcohol, v. sl. sol. absolute $MeOH$. Decomposed by fusion. A 9.6 p.c. solution of the hydrochloride exhibits $\alpha = +2^\circ$.— $BHCl$: [236°]; needles (from methyl alcohol-ether).— $BHAuCl_4$: [220°]; lemon-yellow needles.

Benzoyl derivative. Hydrochloride $C_{17}H_{19}NO.HCl$. The first product of the action of hydrochloric acid on methyl-cocaine [47°], the base being just dissolved in HCl and then heated $\frac{1}{2}$ hour at 90°. Glassy columns (from hot water). The base is not pptd. by carbonate of soda.—Aurochloride $C_{17}H_{19}NO_4.HCl.AuCl_4$. The nitrate is v. sl. sol. water.

METHYLENE. The radicle CH_2 , which is not known to exist in the free state.

Dimethylene C_2H_4 , i.e. $CH_2.CH_2$, is called ETHYLENE (q. v.).

Trimethylene C_3H_6 , i.e. $CH_2 \begin{smallmatrix} \diagup CH_2 \\ | \\ \diagdown CH_2 \end{smallmatrix}$. H.F.p.

-8470. H.F.v. -4680. This gas is formed

when trimethylene bromide $CH_2Br.C_3H_6.Br$ (140 g.) is boiled with sodium (5 g.). The contents of the flask become pasty, but still contain much of the bromide (120 g.), which can be mostly recovered by filtration (Freund, J. pr. [2] 26, 367). It is also formed by heating trimethylene bromide with zinc-dust and 75 p.c. alcohol (Gustavson, J. pr. [2] 86, 300). Trimethylene burns with a bright flame and smells like butylene.

Reactions.—1. Trimethylene is readily absorbed by fuming HCl . The product is *n*-propyl iodide, whereas propylene gives *iso*-propyl iodide. 2. Trimethylene is very slowly absorbed by bromine; the product is trimethylene bromide (165°). Propylene is readily absorbed, forming propylene bromide.—3. Conc. H_2SO_4 forms liquid hydrocarbons, and on diluting and distilling *n*-propyl alcohol is got (G.).—4. $KMnO_4$ does not oxidise it (Wagner, B. 21, 1230).

Reference.—TRIMETHYLENE CARBOXYLIC ACIDS, TRIMETHYLENYL METHYL KETONE, and PHENYL TRIMETHYLENYL KETONE.

Tri-methylene is a term also applied to the divalent radicle $CH_2.CH_2.CH_2$.

Tetra-methylene is a term applied to the ring $CH_2.CH_2$, and it is also used to denote the group

Pentamethylene is a name used to denote

Hexamethylene is benzene hexahydride. According to Baeyer (A. 258, 156), it should be regarded as lying entirely in one plane.

METHYLENE ACETATE v. *Acetyl derivative of formic orthoaldehyde*, vol. ii. p. 570.

TRIMETHYLENE-ACETO-ACETIC ACID, so-called, v. vol. i. p. 24.

METHYLENE-DIAMINE *Di-benzoyl derivative* $CH_2(NHPh)_2$. [221°]. S. (alcohol) 47 at 14.5°; 63 at 22°; *Hipparaffin*.

Formation.—From hippuric acid, PbO_2 and HNO_3 or H_2SO_4 (H. Schwarz, A. 75, 201; Sitz. W. 77, ii. 762; J. Maier, A. 127, 162; Kraut a. Y. Schwarz, A. 223, 40).

Preparation.—From benzonitrile (15 g.), methylal (6 g.) and conc. H_2SO_4 (100 g.) (Hepp a. Spiess, B. 9, 1424).

Properties.—Long white felted needles (from alcohol), v. sol. CS_2 , ether, and chloroform.

Reactions.—1. Dissolves unchanged in conc. H_2SO_4 , and in fuming HNO_3 .—2. On distillation some passes over unchanged along with benzoic acid.—3. Not affected by bromine.—4. Boiled for some time with dilute (32 p.c.) H_2SO_4 , it gives formic aldehyde, NH_3 and benzoic acid.—5. Heated in sealed tubes with dilute HCl it yields benzamide and formic paraldehyde.

Trimethylene-diamine $C_3H_8N_2$, i.e. $NH_2.CH_2.CH_2.CH_2.NH_2$ (c. 140°). Formed by heating trimethylene bromide (1 mol.) and NH_3 (20 mols.) in alcohol for 10 hours at 100°. The liquid is decanted from NH_4Br and evaporated, treated with KOH and distilled (Fischer a. Koch, B. 17, 1799; Lellmann a. Würthner, A. 228, 227). Colourless mobile liquid, easily miscible with alcohol, ether, and benzene. Fumes in moist air, combining with water to form a

hydrate. Readily takes up CO_2 becoming solid. Condenses with benzoic aldehyde forming $\text{C}_6\text{H}_4(\text{N}:\text{C}_6\text{H}_4)_2$. Phenanthraquinone forms $\text{C}_{14}\text{H}_8\text{N}_2\text{O}_2$, a yellow powder, melting above 250° .

Benzil forms $\text{CH}_2\langle\text{CH}_2\text{N}:\text{CPh}\rangle$ a transparent vitreous mass [c. 76°].

Salts.— $\text{B}''\text{H}_2\text{Cl}_2$. Easily soluble prisms.— $\text{B}''\text{H}_2\text{Cl}_2\text{PtCl}_6$. Orange prisms.— $\text{B}''(\text{HSCN})_2$. [102°]. At 140° it is partially decomposed into trimethylene thio-urea and NH_4SCN .— $\text{B}''\text{H}_2\text{Br}_2$.

Diacetyl derivative $\text{C}_6\text{H}_4(\text{NHAc})_2$. [79°]. White needles, v. e. sol. water, v. sol. alcohol, chloroform, sl. sol. benzene, insol. ether, petroleum ether (Strache, B. 21, 2364).

Dibenzoyl derivative $\text{C}_6\text{H}_4(\text{NHBz})_2$. [148°]. White crystalline powder, insol. water, m. sol. benzene, v. sol. alcohol and chloroform. On heating in a stream of HCl the product is $\text{C}_6\text{H}_4\langle\text{NH}\rangle\text{CPh}$, an oily base which slowly becomes crystalline and forms crystalline salts (Hofmann, B. 21, 2337).

Oxalyl derivative $\text{CH}_2\langle\text{CH}_2\text{NH.CO}\rangle$.

A sparingly soluble white powder, formed on mixing trimethylene-diamine with an alcoholic solution of methyl oxalate. It does not melt at 250° .

Derivative.—V. OXY-TRI-METHYLENE-DIAMINE.

Trimethylene di-nitro-di-amine $\text{C}_3\text{H}_6\text{N}_4\text{O}_4$, i.e. $\text{NO}_2\text{NH}(\text{CH}_2)_3\text{NH}(\text{NO}_2)$. [67°]. Formed by heating $\text{C}_3\text{H}_6(\text{N}(\text{NO}_2)\text{CO.Me})_2$ (v. TRI-METHYLENE DICARBAMIC ACID) with aqueous ammonia (Franchimont a. Klobbie, R. T. C. 7, 343). Short thick prisms (from water or alcohol), v. sol. water and alcohol, less sol. ether and chloroform. Boiled with dilute (2 p.c.) H_2SO_4 it evolves N_2O . It has no acid reaction, and easily forms metallic derivatives.

Tetra-methylene-diamine $\text{C}_4\text{H}_{12}\text{N}_2$, i.e. $\text{NH}_2(\text{CH}_2)_4\text{NH}_2$. [24°]. (159°). Obtained by reducing ethylene cyanide in alcoholic solution with sodium (Ladenburg, B. 19, 780). Identical with the ptomaine 'putrescine' (cf. L. Brieger, 'Die Ptomaine', Berlin, 1885-1886, 1, 43; 3, 101) and also with a base obtained from a morbid urine (Udranszky a. Baumann, B. 21, 2938). Strong base, smelling like piperidine. Solutions of its salts give a crystalline pp. with iodine dissolved in KIAq but no pp. with HgCl_2 or KClI_2 . When shaken with aqueous NaOH and BzCl it gives a crystalline pp. of the di-benzoyl derivative. Methyl chloroformate ClCO_2Me forms $(\text{CH}_2)_4(\text{NH.CO.Me})_2$, which crystallises in flattened needles [128°], sl. sol. cold water, and is nitrated by HNO_3 , yielding $(\text{CH}_2)_4(\text{N}(\text{NO}_2)\text{CO.Me})_2$, which crystallises from ether and melts at 62° (Dekkers, R. T. C. 3, 97).

Salts.— $\text{B}''\text{H}_2\text{Cl}_2$. Plates (from alcohol).— $\text{B}''\text{H}_2\text{PtCl}_6$. Needles.—Picrate. Thin yellow needles.—Aurochloride. [210°]. Minute thread-like needles, v. hot water (Giamician a. Zanetti, B. 22, 1978).

Di-benzoyl derivative $\text{C}_6\text{H}_4(\text{NHBz})_2$. [175°] (U. a. B.); [178°] (C. a. Z.). Plates, insol. water, almost insol. ether, v. sol. hot alcohol. May be sublimed.

Tetra-methylene-di-nitro-di-amine $\text{C}_4\text{H}_{10}\text{N}_4\text{O}_4$, i.e. $(\text{CH}_2)_4(\text{NH.NO}_2)_2$. [168°]. Got by heating Vol. III.

$(\text{CH}_2)_4(\text{N}(\text{NO}_2)\text{CO.Me})_2$ with conc. NH_4Aq at 100° and ppg. by HOAc (D.). Small hard crystals (from water).

Penta-methylene diamine $\text{C}_5\text{H}_{12}\text{N}_2$, i.e.

$\text{NH}_2(\text{CH}_2)_5\text{NH}_2$. [178-5°] (L.); (178°-180-5°) (Perkin, C. J. 55, 699). S.G. 2.9174 (L.); 2.8846; 2.8784. M. M. 7.493 (P.). Formed from trimethylene cyanide by reduction in ethereal solution with zinc and HCl , or in alcoholic solution with sodium (Ladenburg, B. 16, 1151; 18, 2956; 19, 780, 2585). It is identical with 'cadaverine' a base discovered by Brieger in corpses, and among the products of putrefaction of flesh and fish (Brieger, B. 16, 1186; 18, 1922; 'Die Ptomaine', Berlin, 1885; Ladenburg, B. 19, 2585). Found also in the urine of a patient suffering from cystinuria, but not in normal urine (U. a. B.). Syrup, smelling like piperidine; v. sol. water and alcohol, m. sol. ether. Fumes in the air. Absorbs CO_2 from the air. The hydrochloride is converted by dry distillation into NH_3 , HCl , and piperidine.

Salts.— $\text{B}''\text{H}_2\text{Cl}_2$.— $\text{B}''\text{H}_2\text{PtCl}_6$. Thick orange prisms (from water); m. sol. cold water.—Picridide. Almost black crystals (from alcohol).— $\text{B}''\text{H}_2\text{Cl}_2 \cdot 3\text{HgCl}_2$. Crystals (from hot water) (L.).— $\text{B}''\text{H}_2\text{Cl}_2 \cdot 4\text{HgCl}_2$. Crystals (from alcohol) (B.).

Di-acetyl derivative

$\text{CH}_3(\text{CH}_2)_5\text{CH}_3\text{NHAo}$. Small needles (from alcohol). May be distilled.

Di-benzoyl derivative

$\text{CH}_3(\text{CH}_2)_5\text{CH}_3\text{NHBz}$. [130°]. (above 360°). Ppd. by adding aqueous NaOH and BzCl to a solution of the base (Udranszky a. Baumann, B. 21, 2744). Long needles and plates; v. sol. alcohol, m. sol. ether, insol. water. Not affected by hot dilute acids or alkalis.

Penta-methylene-di-nitro-di-amine

$\text{CH}_2(\text{CH}_2)_5\text{NH}(\text{NO}_2)_2$. Formed by treating $\text{CH}_2(\text{CH}_2)_5\text{N}(\text{NO}_2)\text{CO.Me}$ with aqueous ammonia (Franchimont a. Klobbie, R. T. C. 7, 343). Small oblong plates (from chloroform); v. sol. water and alcohol, sol. ether, sl. sol. CHCl_3 . When boiled with dilute (2 p.c.) H_2SO_4 it evolves N_2O .

Di-nitroso-penta-methylene-tetramine (so-called) $\text{C}_5\text{H}_{10}\text{N}_4\text{O}_2$, i.e. $\text{C}_5\text{H}_{10}\text{N}_4(\text{NO})_2$. [207°] (G.); [203°] (M.). Formed by the action of nitrous acid on 'hexamethylene tetramine' (Griess, B. 21, 2788; Mayer, B. 21, 2888). Needles (from alcohol), v. sol. hot alcohol, m. sol. chloroform, insol. ether. Not affected by boiling with zinc-dust. Dilute HCl decomposes it into nitrogen, ammonia, and formic aldehyde.

Hexa-methylene-tetramine (so-called)

$\text{C}_6\text{H}_{12}\text{N}_4$. **Hexamethylenetetramine**. [189°]. S. (alcohol) 7. Mol. w. 115 (by Raoult's method) (calc. 140) (Tollens a. Mayer, B. 21, 1566). Formed by passing dry NH_3 over heated tri-oxy-methylene (formic paraldehyde) (Butlerow, Z. 115, 322; Z. 21 5, 278). Prepared by dissolving methylal in dilute H_2SO_4 and distilling the product with steam into a receiver containing ammonia (Wohl, B. 19, 1842).

Properties.—Rhombhedra (from alcohol), v. sol. water, chloroform, and CS_2 . May be sublimed. Scarcely attacked by sodium-amalgam. Acts nutritiously upon algae (Loew a. Bokorny, J. pr. [2] 86, 272).

Reactions.—1. Split up by boiling dilute

METHYL-CYANO-SUCCINIC ETHER

C_6H_9NO , i.e. $CO.Et.CH_2.CMeCy.CO.Et$. An oil formed by treating cyano-succinic ether with Na and MeI successively (Barthe, C. R. 108, 297).

s-Di-methyl-cyano-succinic ether $C_8H_{11}NO$, i.e. $CO.Et.CHMe.CMeCy.CO.Et$. (278°). S.G. 25 1.0577. A product of the action of alcoholic KCy on α -bromo-propionic ether (Zelinsky, B. 21, 3164). Formed also by adding α -bromo-propionic ether to cyano-propionic ether mixed with KCy (Z.).

METHYL-CYANURIC ACID v. *Cyanuric acid* in the article CYANIC ACIDS.

METHYL CUMYL KETONE $C_{12}H_{18}O$ i.e. $CH_3.CO.C_6H_4.Me.C_6H_5$. [21°]. (217°). An oil, formed by the action of AcCl on cymene in presence of $AlCl_3$ (Claus, B. 19, 233).

METHYL-DAMBOSE v. BORNEITE, vol. i. p. 524.

Di-methyl-dambosé v. DAMRONITE.

METHYL-DAPHNETIN v. DAPHNETIN.

METHYL DECYL KETONE $C_{17}H_{34}O$ i.e. $CH_3.CO.C_{10}H_{21}$. [21°]. (217°). Formed by distilling a mixture of barium acetate and barium benedecate (undecylate) (Krafft, B. 15, 1708). Yields acetic and decanoic acids on oxidation.

METHYL-DESOXYBENZOLIN v. TOLYL BENZYL KETONE.

Dimethyl-desoxybenzoin v. BENZYL XYLIL KETONE.

METHYL DODECYL KETONE $C_{17}H_{34}O$ i.e. $CH_3.CO.C_{12}H_{25}$. [34°]. (206° at 100 mm.). Formed by distilling barium tridecoteate ($C_{12}H_{25}O_2$)₂Ba with barium acetate (Krafft, B. 15, 1708). Yields lauric and acetic acids on oxidation.

METHYL c-DURYL KETONE $C_{12}H_{18}O$ i.e. $CH_3.CO.C_6H_4.Me$, [1:2:3:4:5]. (259°). From *c*-durene, AcCl, and $AlCl_3$ (Claus a. Föhlich, J. pr. [2] 88, 230). Oil.

Phenyl hydrazide. [129°]. Lamine.

Isomerides v. DURL METHYL KETONES.

METHYL-ECGONINE $C_{16}H_{17}NO_3$. [264°]. A product of the action of HCl on methyl-cocaine, the resulting methyl-ecgonine hydrochloride being decomposed by Ag_2O (Liebermann a. Giesel, B. 23, 510). May be crystallised from methyl alcohol containing a trace of water. Extremely sol. water, insol. absolute alcohol, v. sl. sol. absolute MeOH. Decomposed by fusion. A 9.6 p.c. solution of the hydrochloride exhibits $\alpha = +2^\circ$.— $BHCl$: [236°]; needles (from methyl alcohol-ether).— $B^H AuCl_4$: [220°]; lemon-yellow needles.

Benzoyl derivative. Hydrochloride $C_{17}H_{21}NO_3.HCl$. The first product of the action of hydrochloric acid on methyl-cocaine [47°], the base being just dissolved in HCl and then heated $\frac{1}{2}$ hour at 90°. Glassy columns (from hot water). The base is not pptd. by carbonate of soda.—Aurochloride $C_{17}H_{21}NO_3.HCl.AuCl_4$. The nitrate is v. sl. sol. water.

METHYLENE. The radicle CH_2 , which is not known to exist in the free state.

Dimethylene C_2H_4 , i.e. $CH_2.CH_2$, is called ETHYLENE (q. v.).

Trimethylene C_3H_6 , i.e. $CH_2 \begin{smallmatrix} \diagup CH_2 \\ | \\ CH_2 \end{smallmatrix}$. H.F.p.

—8470. H.F.v. —4630. This gas is formed

when trimethylene bromide $CH_2Br.C_3H_6.BrCH_2$ (140 g.) is boiled with sodium (5 g.). The contents of the flask become pasty, but still contain much of the bromide (120 g.), which can be mostly recovered by filtration (Freund, J. pr. [2] 26, 367). It is also formed by heating trimethylene bromide with zinc-dust and 75 p.c. alcohol (Gustavson, J. pr. [2] 86, 300). Trimethylene burns with a bright flame and smells like butylene.

Reactions.—1. Trimethylene is readily absorbed by fuming HI. The product is *n*-propyl iodide, whereas propylene gives *iso*-propyl iodide. 2. Trimethylene is very slowly absorbed by bromine; the product is trimethylene bromide (165°). Propylene is readily absorbed, forming propylene bromide. — 3. Conc. H_2SO_4 forms liquid hydrocarbons, and on diluting and distilling *n*-propyl alcohol is got (G.). — 4. $KMnO_4$ does not oxidise it (Wagner, B. 21, 1230).

Reference.—TRIMETHYLENE CARBOXYLIC ACIDS, TRIMETHYLENYL METHYL KETONE, and PHENYL TRIMETHYLENYL KETONE.

Tri-methylene is a term also applied to the divalent radicle $CH_2.CH_2.CH_2$.

Tetra-methylene is a term applied to the ring $CH_2.CH_2$, and it is also used to denote the group

Pentamethylene is a name used to denote

Hexamethylene is benzene hexahydride. According to Baeyer (A. 258, 156), it should be regarded as lying entirely in one plane.

METHYLENE ACETATE v. *Acetyl derivative of formic orthoaldehyde*, vol. ii. p. 570.

TRIMETHYLENE-ACETO-ACETIC ACID, so-called, v. vol. i. p. 24.

METHYLENE-DIAMINE *Di-benzoyl derivative* $CH_2(NH_2)_2$. [221°]. S. (alcohol) 47 at 14.5°; 63 at 22°; *Hipparaffin*.

Formation.—From hippuric acid, PbO_2 and HNO_3 or H_2SO_4 (H. Schwarz, A. 75, 201; Sitz. W. 77, ii. 762; J. Maier, A. 127, 162; Kraut a. Y. Schwarz, A. 223, 40).

Preparation.—From benzonitrile (15 g.), methylal (6 g.) and conc. H_2SO_4 (100 g.) (Hepp a. Spiess, B. 9, 1424).

Properties.—Long white felted needles (from alcohol), v. sol. CS_2 , ether, and chloroform.

Reactions.—1. Dissolves unchanged in conc. H_2SO_4 , and in fuming HNO_3 . — 2. On distillation some passes over unchanged along with benzoic acid. — 3. Not affected by bromine. — 4. Boiled for some time with dilute (32 p.c.) H_2SO_4 , it gives formic aldehyde, NH_3 and benzoic acid. — 5. Heated in sealed tubes with dilute HCl it yields benzamide and formic paraldehyde.

Trimethylene-diamine $C_3H_8N_2$, i.e. $NH_2.CH_2.CH_2.CH_2.NH_2$ (c. 140°). Formed by heating trimethylene bromide (1 mol.) and NH_3 (20 mols.) in alcohol for 10 hours at 100°. The liquid is decanted from NH_4Br and evaporated, treated with KOH and distilled (Fischer a. Koch, B. 17, 1799; Lellmann a. Würthner, A. 228, 227). Colourless mobile liquid, easily miscible with alcohol, ether, and benzene. Fumes in moist air, combining with water to form a

$C_2H_5(NH.CO_2Et)_2$ (Fischer & Koch, A. 232, 225). It crystallises after some time, and separates from ether in colourless prisms. V. sol. ether, alcohol, and chloroform, sl. sol. ligroin, insol. water. It dissolves in acids but is reppd. by alkalis.

Tetra-methylene dicarbamic acid. *Methyl ether* $C_4H_8(NH.CO_2Me)_2$. [128°]. Formed from tetra-methylene-diamine and $ClCO_2Me$ (Dekkers, R. T. C. 9, 97). Flattened needles, sol. warm water. Converted by HNO_3 into $C_4H_8(N(NO_2).CO_2Me)_2$ which separates from ether in small brilliant crystals [62°], v. sl. sol. cold water, sl. sol. ether, sol. warm alcohol, and is converted by NH_3 aq into $C_4H_8(NH.NO_2)_2$ [163°].

Pentamethylene dicarbamic acid. *Methyl ether* $CH_2(CH_2CH_2NH.CO_2Me)_2$. [114°]. Formed by treating penta-methylene-diamine with methyl carbonate. Fine needles (from boiling water). V. sol. hot alcohol (Franchimont & Klobbie, R. T. C. 7, 313). Pure HNO_3 gives a di-nitro-derivative, forming small brilliant prisms [37°], and this treated with aqueous ammonia gives penta-methylene-dinitramine [60°] together with methyl carbamate.

TRIMETHYLENE CARBOXYLIC ACID

$C_4H_6O_4$, i.e. $\begin{array}{c} CH_2 \\ | \\ CH_2 \end{array} \begin{array}{c} CH_2CO_2H \\ | \\ CH_2CO_2H \end{array}$ or $CH_2.CH.CH_2.CO_2H$. *Isomeride of crotonic acid.* [19°]. (183°). Formed by heating ethylene-malonic acid (trimethylene dicarboxylic acid) at 210° (Röder, A. 227, 24; Perkin, jun., C. J. 47, 817; B. 17, 57). White crystals, m. sol. water. Has a powerful odour and a burning taste.— CaA' , 6aq. Needles, v. sol. water.— BaA' , 2aq. Needles, v. sol. water.— AgA' . Small needles (from hot water). Gives off a low-boiling oil on distillation.

Ethyl ether EtA' . (131°). Formed by digesting the Ag salt with an ethereal solution of EtI . Volatile oil, with pleasant odour. Not affected by bromine in the cold, and only slowly attacked when boiled with bromine, HBr being given off.

Trimethylene (1:1)-di-carboxylic acid so called

$C_4H_6O_4$, i.e. $\begin{array}{c} CH_2 \\ | \\ CH_2 \end{array} \begin{array}{c} C(CO_2H)_2 \\ | \\ C(CO_2H)_2 \end{array}$ or

$CH_2.CH.CH(CO_2H)_2$. *Vinaconic acid. Ethylene-malonic acid.* [141°]. Obtained by saponification of its ether. Colourless triclinic crystals; $a:b:c = 0.7712:1:0.8702$. Crystallises with aq (from water); v. e. sol. water, v. sol. ether. At 160° it begins to give off CO_2 , leaving trimethylene carboxylic acid. It is not attacked by sodium-amalgam. When heated with bromine it gives off HBr slowly. It combines, however, with HBr , forming bromo-ethyl-malonic acid (Perkin, O. J. 47, 814), and it combines with bromine when this is dissolved in chloroform (Fittig). Boiling dilute H_2SO_4 forms γ -oxy-ethyl-malonic acid. Alkaline $KMnO_4$ does not attack it (Buchner, B. 23, 704).

Salts.—Ammonium salt. Four-sided plates.— CuA' aq. Deep-blue octahedra, sl. sol. hot water. At 160° it becomes a light-green powder.— BaA' . Needles.— BaH_2A' , 4aq. Prismatic needles.— PbA' (dried at 100°). Insol. gold, sl. sol. hot, water.— AgA' . Needles, v. sl.

sol. cold water, sl. sol. hot water.— $AgHA'$. Long colourless needles (from water).

Ethyl ether Et_2A' . (213°). V.D. 6.32 (calc. 6.43). S.G. $\frac{4}{15}$ 1.0646; $\frac{2}{25}$ 1.0566. Formed by the action of ethylene bromide on sodium-malonic ether (Perkin, jun., C. J. 47, 812; B. 17, 54; Fittig & Röder, A. 227, 13). Oil. Not attacked when successively treated with benzyl chloride and $NaOEt$ (Perkin, jun., B. 18, 1734).

Dibromide $C_4H_6Br_2(COOH)_2$. [110°]. From tri-methylene-di-carboxylic acid and Br in chloroform (Fittig & Marburg, B. 18, 3413).

Trimethylene (1:2)-di-carboxylic acid

$\begin{array}{c} CH_2CO_2H \\ | \\ CH_2 \end{array} \begin{array}{c} CH_2CO_2H \\ | \\ CH_2CO_2H \end{array}$ or $CH_2.C(CO_2H).CH_2.CO_2H$.

Allo-itaconic acid. [137°] (C. a. G.); [139°] (B.).

Formation.—1. By heating its anhydride with water at 140° (Conrad & Guthzeit, B. 17, 1187).—2. From sodium propane tetracarboxylic ether $(CO_2Et)_2CNa.CH_2.CNa(CO_2Et)_2$ by treatment with bromine, the resulting trimethylene tetracarboxylic ether being saponified, and the free acid heated to 230°, and then distilled under 16 mm. pressure: the oil which passes over at 170° to 180° is heated with water at 140° (Perkin, jun., B. 19, 1056; Dressel, A. 256, 197).

Properties.—Prisms; v. sol. water, alcohol, and ether. Not attacked by alkaline $KMnO_4$, or by sodium-amalgam (Buchner, B. 23, 705).

Salts.— CaA'' : silky crystals.— AgA'' .

Anhydride $C_3H_2O_4$, i.e. $\begin{array}{c} CH_2CO \\ | \\ CH_2CO \end{array} \begin{array}{c} CH_2CO \\ | \\ CH_2CO \end{array} O$ or

$CH_2.C \begin{array}{c} CO.O \\ | \\ CH_2CO \end{array} .$ [37°] (C. a. G.); [59°] (Buchner).

Formed by heating trimethylene-

tricarboxylic acid $\begin{array}{c} CH_2CO_2H \\ | \\ C(CO_2H)_2 \end{array}$ or possibly

$CH_2.C(CO_2H).CH(CO_2H)_2$, at 184° to 190° for a long time (C. a. G.). Needles, sl. sol. ether.

Trimethylene (1:2)-di-carboxylic acid

$\begin{array}{c} CH_2CO_2H \\ | \\ CH_2 \end{array} \begin{array}{c} CH_2CO_2H \\ | \\ CH_2CO_2H \end{array}$. [175°]. *cis-trans-tri-methyl-*

enc-1:2-di-carboxylic acid. Formed by saponification of the di-methyl-ether (Eduard Buchner, B. 23, 705). Compact apparently rhombic crystals (from water), containing no water of crystallisation. Grouped needles (from ether). Less sol. water than the isomeric glutaconic acid, but more sol. ether. Distils without splitting off water. Acetyl chloride forms no anhydride. Not oxidised by permanganate in alkaline solution. Not reduced by sodium-amalgam. Chloride of iron gives a weak red-brown colour.

Salts.—The zinc salt is more sol. cold than hot water. It crystallises in nodular groups of needles. A solution of the ammonium salt gives no opp. with $CaCl_2$ and $BaCl_2$, but white crystalline pps. with silver and lead salts. By heating the silver salt a white body sublimes in needles, probably the anhydride.

Di-methyl-ether $C_4H_8(CO_2Me)_2$. (905°–215° at 718 mm.). Formed by heating acrylo-di-azo-acetic ether $C_4H_8N_2(CO_2Me)_2$ for 40 minutes to 160°–185°. Saponified by boiling with aqueous potash.

Isomerides of trimethylene dicarboxylic acid
v. ITACONIC, CITRACONIC, MESACONIC, and GLUTA-
CONIC ACIDS.

Trimethylene (1:1:2)-tricarboxylic acid

$C_3H_4O_6$, i.e. $CH_2 \begin{matrix} \diagup CH_2CO_2H \\ \diagdown C(CO_2H)_2 \end{matrix}$ or possibly
 $CH_2:C(CO_2H).CH(CO_2H)_2$ [184°]. Formed by
saponification of its ether, which is prepared by
the action of $\alpha\beta$ -di-bromo-propionic ether on di-
iodo-malonic ether (Conrad a. Guthzeit, *B.* 17,
1185). Its ether is also formed by the action of
 α -bromo-acrylic ether upon sodio-malonic ether
 $CHNa(CO_2Et)_2$ (Michael, *J. pr.* [2] 35, 132, 351;
Am. 9, 121). Prisms (from water). At 184°-
190° it is split up into CO_2 and the dicarboxylic
acid or its anhydride.

Tri-ethyl ether Et_3A''' . (276°). S.G. 1.127.
Colourless liquid. Does not react with
 $NaOEt$ and $BzCl$.

Trimethylene (1:2:3)-tri-carboxylic acid

$(CO_2H)CH \begin{matrix} \diagup CH(CO_2H) \\ \diagdown C(CO_2H)_2 \end{matrix}$ or possibly
 $CO_2H.CH:C(CO_2H).CH_2.CO_2H$. [150°-153°].
Formed by heating the tetra-carboxylic acid
(1:1:2:3) at 200° for a long time (Perkin, *B.* 17,
1654; *C. J.* 47, 826). Colourless crystalline
solid. V. sol. water, alcohol, and acetone, sl.
sol. benzene, chloroform, ligroin, and CS_2 . On
heating it yields a sublimate, probably of an an-
hydride.

Salts.— $A'''Ag$: white granular pp. —
 $A'''Ca_3$: crystalline pp., soluble in cold water,
nearly insoluble in hot. The cupric salt is a
beautiful light-green pp., sl. sol. water. The
Ba and Pb salts are white pps.

Trimethylene (1, 2, 3)-tri-carboxylic acid

$CO_2H.CH \begin{matrix} \diagup CH_2CO_2H \\ \diagdown CH_2CO_2H \end{matrix}$. [220°]. Obtained by
saponifying its methyl ether with alcoholic
potash (Buchner, *B.* 21, 2641). Small aggregates
of needles (from ether), v. sol. alcohol and water,
sl. sol. ether. Not affected by bromine or by
 $KMnO_4$. Its ammonium salt crystallises in
plates.

Methyl ether Me_3A''' . [61°]. (267°) at
732 mm.; (224° at 180 mm.). Obtained by dis-
tilling the compound of methyl fumarate with
methyl diazo-acetate. Needles (from alcohol or
water), v. sol. alcohol, ether, benzene, and petro-
leum-ether.

Anhydride $C_3H_2(CO_2H) \begin{matrix} \diagup CO \\ \diagdown CO \end{matrix} O$. [189°].

(265° at 75 mm.). Obtained by distilling the
acid under reduced pressure. Small prisms, v.
sol. water and alcohol, v. sol. ether. Its Pb,
Ba, and Ag salts are m. sol. water.

Trimethylene (1,1,2,3)-tetra-carboxylic acid

$(CO_2H)_2C \begin{matrix} \diagup CH_2(CO_2H) \\ \diagdown CH(CO_2H) \end{matrix}$ or possibly,
 $(CO_2H)_2C:C(CO_2H).CH_2.CO_2H$ [95°-100°]. The
tetra-ethyl ether of this acid is obtained by the
action of di-bromo-succinic ether on di-sodio-
malonic ether (Perkin, *B.* 17, 1652; *C. J.* 47,
824). Crystalline colourless solid. V. sol. water,
alcohol, ether, and acetone, sl. sol. ligroin and
benzene. Very strong acid. The acid loses CO_2

on heating to 200° giving the (1, 2, 3)-tri-car-
boxylic acid.

Salts.— $A'Ag$: white amorphous pp.—
 $A'Ca_3$: crystalline pp., more soluble in cold
water than in hot.

Tetra-ethyl ether $A'Et_4$: (246° at 85
mm.); thick colourless oil.

Tri-methylene (1,1,2,2)-tetra-carboxylic

acid $CH_2 \begin{matrix} \diagup C(CO_2H)_2 \\ \diagdown C(CO_2H)_2 \end{matrix}$. [240°]. Formed by

saponifying the ethyl ether with alcoholic
 $KOHAq$ (Dressel, *A.* 256, 196). Large shining
crystals (from water). When heated to 230° it
gives off $2CO_2$ and H_2O and is converted into the
anhydride of trimethylene dicarboxylic acid, and
from this the dicarboxylic acid itself can be ob-
tained by heating with water to 140°.

Ethyl ether $H_2C \begin{matrix} \diagup C(CO_2Et)_2 \\ \diagdown C(CO_2Et)_2 \end{matrix}$. [43°].

(187°). Formed by the action of bromine on
the disodium compound of propane tetra-car-
boxylic ether (Dressel, *A.* 256, 194; *cf.* Perkin,
B. 19, 1056). Long needles, v. sol. ether, alcohol,
 $CHCl_3$ and benzene (D.).

Tetra-methylene carboxylic acid $C_4H_4O_6$, i.e.

$CH_2 \begin{matrix} \diagup CH_2 \\ \diagdown CH_2 \end{matrix} CH_2CO_2H$. (191°) at 720 mm.
S.G. $\frac{15}{15}$ 1.0548; $\frac{25}{25}$ 1.0476. M.M. 5.048 at 18°.
 μ_D 1.4403 at 26°. Formed by heating tetra-
methylene dicarboxylic acid at 200°, CO_2 being
given off (Perkin, *B.* 16, 1795; *C. J.* 51, 8).
Colourless oil, smelling like butyric acid; sl. sol.
water, miscible with alcohol and ether. Not
attacked by bromine below 100°.

Reaction.—The calcium salt distilled with
lime gives C_2H_4 , H_2 , CH_4 , CO , di-tetramethyl-
enyl ketone, and tetramethylenyl methyl ketone
(Colman a. Perkin, jun., *C. J.* 51, 228; *B.* 19,
3112).

Salts.— AgA' : sparingly soluble white pp.—
 CaA'_2 , 5aq.

Ethyl ether Et_4A' . (151°) at 720 mm. (F.);
(162°) (Freund, *B.* 21, 2694).

Chloride C_4H_4COCl . (143°) (F.). Ob-
tained by heating the amide with PCl_5 .

Amide $C_4H_4CONH_2$. [138°]. (c. 240°).
Formed by heating the ammonium salt of the
acid to 250° (Freund, *B.* 21, 2694). Plates (from
alcohol), v. sol. water, ether, chloroform, benz-
ene. May be sublimed. Decomposed by treat-
ment with bromine and KOH .

Nitrile C_4H_4CN . (150°). Formed by dis-
tilling the amide of tetra-methylene carboxylic
acid with phosphoric anhydride (Freund, *B.* 21,
2696). Colourless oil, with pleasant odour. Is
converted into the amine by reducing with
sodium and alcohol.

Anilide $C_4H_4CONHPh$. [111°]. Formed
by heating the amide with aniline until no more
ammonia is given off (Freund). Long needles
(from alcohol), sl. sol. hot water.

Anhydride $(C_4H_4CQ)_2O$. (160°). Formed
by distilling the sodium salt with the chloride
of the acid (F.).

Tetra-methylene (1,1)-dicarboxylic acid

$C_4H_4O_6$, i.e. $CH_2 \begin{matrix} \diagup CH_2 \\ \diagdown CH_2 \end{matrix} C(CO_2H)_2$. [156°]. From
the ether (Perkin, *C. J.* 51, 4). Monoclinic
crystals (from ether); $a:b:c=1.0324:1.1:1.854$;
 $\beta=88^\circ 58'$. V. sol. ether and benzene, nearly

insol. chloroform and ligroin, v. sol. water. A few degrees above its melting-point it splits off CO_2 , becoming tetramethylene carboxylic acid.

Salts.— $\text{Ag}_2\text{A}''$.— CuA'' aq.— PbA'' aq.— BaA'' aq.

Ethyl ether Et.A''. (221°) at 720 mm. S.G. $\frac{1}{4}$ 1.0588; $\frac{3}{4}$ 1.0405. M.M. 9.940 at 18.9°. $\frac{1}{2}$ 1.433. Formed from malonic ether, trimethylene bromide, and NaOEt (Perkin, *B.* 16, 1793; *C. J.* 51, 2). Oil, smelling like camphor.

Tetramethylene (1,2)-di-carboxylic acid

$\text{CH}_2\text{CH}(\text{CO}_2\text{H})$
 $\text{CH}_2\text{CH}(\text{CO}_2\text{H})$ [130°]. Formed by heating

the tetra-carboxylic acid to 180°–200° (Perkin, *B.* 19, 2042; *C. J.* 51, 22). Colourless feathery crystals (from water). V. sol. water, alcohol, and ether, more sparingly sol. benzene and ligroin. By alkaline KMnO_4 it is oxidised to oxalic acid.

Salts.— $\text{A}''\text{Ag}_2$: heavy white pp.— $\text{A}''\text{Ba}''$: sparingly soluble six-sided transparent tables.

Di-ethyl ether A''Et. (238°–242°); colourless liquid.

Anhydride $\begin{array}{c} \text{CH}_2\text{CHCO} \\ | \quad | \\ \text{CH}_2\text{CHCO} \end{array} \text{O}$ [78°]; colour-

less crystals; easily soluble in alcohol, sparingly in ether and benzene. Formed by heating the acid to 300°. Reconverted into the acid by boiling with water. Heated with resorcin it gives a beautifully fluorescent condensation-product.

Tetramethylene (1,3)-dicarboxylic acid

$\text{CO}_2\text{HCH}(\text{CH}_2)\text{CH}(\text{CH}_2)\text{CO}_2\text{H}$ *Homotaconic acid*. [171°]. Formed by boiling its ether with fuming HClAq (Markownikoff a. Krestownikoff, *A.* 208, 333). Prisms, v. sol. hot water and alcohol, sl. sol. ether. May be sublimed. Does not combine with bromine, but when heated with Br it gives off HBr and CO_2 . It is not reduced by sodium-amalgam. Does not form an anhydride. Does not unite with HBr or HI .

Salts.— PbA'' aq. Crystalline crusts.— $\text{Ag}_2\text{A}''$. Amorphous pp., not decomposed by boiling water.

Methyl ether Me.A''. (220°).

Ethyl ether Et.A''. (280°). Formed in very small quantity when $\text{CH}_2\text{CH}(\text{OEt})\text{CO}_2\text{Et}$ is prepared by the action of dry NaOEt on α -chloro-propionic ether (M. a. K.).

Tetramethylene (1,1,2,2) - tetra - carboxylic

$\text{CH}_2\text{C}(\text{CO}_2\text{H})_2$ acid [145°–150°]. Obtained by

saponification of the tetra-ethyl ether, which is formed by the action of bromine upon the di-sodio-derivative of butane-tetra-carboxylic

$\text{CH}_2\text{ONa}(\text{CO}_2\text{Et})_2$ ether [Perkin, *B.* 19, 2041;

O. J. 51, 21]. Colourless crystals. Easily soluble in water, alcohol, and ether, more sparingly in benzene and ligroin. It evolves CO_2 at its melting-point, and is converted into the di-carboxylic acid.

Tetramethylene (1,1,3,3) - tetracarboxylic acid. Ethyl ether

$(\text{CO}_2\text{Et})_2\text{C}(\text{CH}_2)_2\text{C}(\text{CH}_2)_2\text{C}(\text{CO}_2\text{Et})_2$. Formed by the action of methylene iodide on the di-sodium de-

rivative of propane tetra-carboxylic ether in an alcoholic solution on the water-bath (Dressel, *A.* 256, 198). Colourless viscid oil, distilling with some decomposition between 220° and 250° at 15 mm.

Pentamethylene dicarboxylic acid

$\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{H})$ [160°].

Preparation.—Disodium pentane tetra-carboxylic ether, $(\text{CO}_2\text{Et})_2\text{ONa}.\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{ONa}(\text{CO}_2\text{Et})_2$, is converted by Br into $\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Et})\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Et})_2$, which

yields pentamethylene tetracarboxylic acid on saponification, and this acid is decomposed by heat into CO_2 and pentamethylene dicarboxylic acid. This is purified by conversion into its ethyl salt (Perkin, jun., *C. J.* 51, 244; *B.* 18, 8250).

Properties.—Nodules (from water). V. sol. hot water, alcohol, and acetic ether; sl. sol. ether.

Salts.— $\text{Ag}_2\text{A}''$. Very stable white pp.

Ethyl ether Et.A''. (c. 250°).

Anhydride $\begin{array}{c} \text{CH}_2\text{CHCO} \\ | \quad | \\ \text{CH}_2\text{CHCO} \end{array} \text{O}$

[64°–67°]. Formed by heating the acid to 300°. M. sol. alcohol and ether, sl. sol. CS_2 ; insol. cold, but saponified by hot, $\text{Na}_2\text{CO}_3\text{Aq}$. With resorcin and H_2SO_4 it gives the fluorescein reaction.

Penta-methylene tetracarboxylic acid

$\text{CH}_2\text{CH}_2\text{C}(\text{CO}_2\text{H})_2\text{CH}_2\text{CH}_2\text{C}(\text{CO}_2\text{H})_2$. Formed as above. Sol. ether.

TETRAMETHYLENE-CARBOXYLIC ALDEHYDE $\text{CH}_2\text{CH}(\text{CH}_2)\text{CH}(\text{CH}_2)\text{CHO}$. (115°–117°). From

calcium tetramethylene carboxylate by distilling with calcium formate (Colman a. Perkin, *C. J.* 51, 238). Oil; smelling like isobutyric aldehyde. Gives a purple colour with rosaniline hydrochloride which has been bleached by SO_2 ; reduces ammoniacal AgNO_3Aq ; combines with NaHSO_3 ; reacts with hydroxylamine and with phenylhydrazine.

TRIMETHYLENE CHLORHYDRIN v. CHLORO-PROPYL ALCOHOL.

METHYLENE CHLORIDE CH_2Cl_2 . *Di-chloro-methane*. Mol. w. 85. (41.8°) (Thorpe, *C. J.* 37, 195). S.G. $\frac{1}{4}$ 1.3778 (T.); $\frac{3}{4}$ 1.3377; $\frac{2}{5}$ 1.3220. M.M. 4.313 at 11.9° (Perkin, *C. J.* 45, 527). C.E. (0°–10°) .001335; (0°–40°) .001416. S.V. 65.12. H.C.p. 106800 (Berthelot a. Ogier, *B.* [2] 36, 69).

Formation.—1. From chlorine and methyl chloride in sunlight (Regnault, *A.* 33, 828; *A. Ch.* [2] 70, 877).—2. By the action of zinc-dust and ammonia on chloroform, the yield being very small (Perkin, *C. N.* 18, 106).—3. By the action of chlorine on methylene iodide (Butlerow, *A.* 107, 110; 111, 251; *Z.* [3] 5, 276).—4. By the action of AlCl_3 on the compound of $\text{ClCO}_2\text{CCl}_2$ with ClCO_2CH_3 (Hentschel, *J. pr.* [2] 86, 474).

Preparation.—Aqueous HCl is cautiously added to a mixture of alcohol (5 vols.), chloroform (1 vol.), and zinc. Sufficient heat is pro-

duced in the reaction to distil over much of the methylene chloride. The product is fractionally distilled (Greene, *C. R.* 89, 1077; *A. Ph. S.* 18, 847; *C. N.* 60, 75; *A. C. J.* 1, 522).

Properties.—Oil. Like CCl_4 (but unlike CH_2Cl and CHCl_3) it exerts a poisonous action when inhaled (Regnault a. Villejean, *C. R.* 100, 1146).

Reactions.—1. Converted by ICl or ICl_3 into CHCl_3 , and hexachloro-benzene. Converted by IBr into iodoform and di-chloro-di-iodo-methane (Höland, *A.* 240, 234). Converted by IBr_3 into CBr_4 , CHBr_3 , and C_2Br_4 .—2. Heated with KI , iodine, and alcohol, it gives CH_2I_2 , EtI , and alcohol (*H.*).—3. Iodine at 200° gives methylene iodide (*H.*).—4. Bromine at 170° forms CHBrCl (91°), and a little CHBr_2Cl (38°) (150°) (Arnhold, *A.* 240, 204).—5. Alcoholic NaOAc forms $\text{CH}_3(\text{OEt})_2$ and acetic acid (*A.*).—6. Converted by alcoholic NH_3 at 125° into so-called hexa-methylene-diamine (Höland, *A.* 210, 225). Aqueous ammonia at 140° forms NH_4Cl , methylamine hydrochloride and formic acid (André, *C. R.* 102, 1474).—7. Mixed with benzene it is converted by AlCl_3 into anthracene and other products (Friedel a. Crafts, *A. Ch.* [6] 11, 264).—8. Water at 200° forms HCl , formic acid, MeCl , and MeOH (André).—9. With H_2S it forms a crystalline compound $\text{CH}_2\text{Cl}_2(\text{H}_2\text{S})_2$ 23aq (Forcrand, *A. Ch.* [5] 28, 17).

TRIMETHYLENE CHLORIDE *v.* $\omega\beta$ -Dichloro-propane.

METHYLENE CHLORO-BROMIDE *v.* Chloro-bromo-methane.

Tri-methylene chloro-bromide *v.* Chloro-bromo-propane.

METHYLENE CHLORO-IODIDE CH_2Cl_2 Chloro-iodo-methane. (109°). V.D. 88.14. S.G. $\frac{1}{15}$ 2.447; $\frac{16}{17}$ 2.444. Formed by the action of ICl on methylene iodide or of iodine on $\text{IHg.CH}_2\text{Cl}$ (Sakurai, *C. J.* 41, 361; 47, 198). Oil.

TRIMETHYLENE CYANHYDRIN *v.* Nitrile of γ -Oxy-butyric acid.

TRIMETHYLENE CYANIDE $\text{C}_3\text{H}_3\text{N}_3$ *i.e.* $\text{CH}_2(\text{CH}_2\text{CN})_2$. Glutaronitrile. (274°) (*H.*); (296°) (Perkin, *C. J.* 55, 702); (203° at 100 mm.); (142° at 10 mm.) (Krafft a. Noerdling, *B.* 22, 817). S.G. $\frac{15}{16}$.9952; $\frac{25}{26}$.9894. M.M. 5.136 (*P.*). Formed from trimethylene bromide and alcoholic KCy (Henry, *Bl.* [2] 43, 618; *C. R.* 100, 742). Liquid, sol. water, alcohol, and chloroform, insol. ether and CS_2 . Yields glutaric acid on saponification. Sodium reduces it in alcoholic solution to pentamethylene-diamine and piperidine.

TRIMETHYLENE-DI-ETHYL-ALKINE *v.* Ethyl-oxypropyl-amine.

METHYLENE-ETHYL-AMINE $\text{C}_2\text{H}_5\text{N}$ *i.e.* EtNCH_2 . (208° i. V.). V.D. 2. Formed by the action of ethylamine on formic aldehyde (trioxymethylene) (Kolotoff, *Bl.* [2] 43, 112; *J. R.* 17, 231). Liquid, with unpleasant odour, sol. cold water, but separates again on warming, *v.* sol. alcohol. HCl splits it up into ethylamine and trioxymethylene (formic paraldehyde).— $\text{B}^2\text{H.PtCl}_4$. Yellow crystalline pp. An isomeride ($\text{CH}_2\text{N.Et}$, of this base is described by Lermontoff (*B.* 7, 1252) as an oil formed by heating

ethylamine with alcoholic methylene iodide at 100° .— $(\text{CH}_2)_3\text{N.Et.H}_2\text{PtCl}_4$. Amorphous.

Methylene tetra-ethyl-diamine $\text{C}_6\text{H}_{12}\text{N}_2$ *i.e.* $\text{CH}_2(\text{NEt}_2)_2$. Tetra-ethyl-di-amido-methane (169° i. V.). S. 10. Formed by heating trioxymethylene (formic paraldehyde) with diethylamine in sealed tubes at 100° (Kolotoff, *Bl.* [2] 43, 112; Ehrenberg, *J. pr.* [2] 36, 118). Liquid, with peppery odour, sl. sol. water, miscible with alcohol, ether, and CHCl_3 . Split up by dilute acids, even by oxalic acid, into NH_4Et and formic aldehyde. Combines with CS_2 , forming $\text{C}_6\text{H}_{12}\text{N}_2\text{CS}_2$.

Tetra-methylene-tetra-ethyl-tetramine $\text{C}_{12}\text{H}_{24}\text{N}_4$ *i.e.* $\text{CH}_2\langle\text{NEt.CH}_2\text{NEt}\rangle\text{CH}_2$. Formed by heating methylene iodide with alcoholic ethylamine at 100° (Lermontoff, *B.* 7, 1252). Liquid, yielding amorphous salts. — $\text{B}^2\text{H.PtCl}_4$: sl. sol. water.

METHYLENE-ETHYL-PHTHALIMIDINE

$\text{C}_{11}\text{H}_{11}\text{NO}$ *i.e.* $\text{C}_6\text{H}_4\langle\text{C}(\text{CH}_2)\text{CO}\rangle\text{NEt}$. Obtained by heating $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}_2$, which is produced by adding aqueous ethylamine to phthalyl-acetic acid (Mertens, *B.* 19, 2369). Colourless oil, smelling of fresh carrots. Volatile with steam; *v.* sol. alcohol and ether.

METHYLENE DI-ETHYL DISULPHIDE

$\text{C}_4\text{H}_{12}\text{S}_2$ *i.e.* $\text{CH}_3(\text{SEt})_2$. Formic aldehyde ethyl mercaptal. Ethyl derivative of di-thio-formic orthoaldehyde. (178° – 181°). S.G. $\frac{23}{24}$.987. Formed from methylene chloride and NaSEt in alcoholic solution (Niederist, *A.* 186, 391; Fromm, *A.* 253, 155).

METHYLENE DI-ETHYL DISULPHONE

$\text{C}_4\text{H}_{12}\text{S}_2\text{O}_2$ *i.e.* $\text{CH}_3(\text{SO}_2\text{Et})_2$. [104°]. Formed by the action of KMnO_4 and H_2SO_4 on $\text{CH}_3(\text{SEt})_2$ (Fromm, *A.* 253, 156; cf. Baumann, *B.* 19, 2811). Needles, *v.* sol. water and alcohol, sl. sol. ether. Chlorine forms $\text{CCl}_3(\text{SO}_2\text{Et})_2$ [99°] crystallising in needles; while bromine produces $\text{CBr}_2(\text{SO}_2\text{Et})_2$ [132°].

Di-methylene di-ethyl trisulphone

$(\text{Et.SO}_2\text{CH}_2)_2\text{SO}_2$. [149°]. Formed by treating formic aldehyde with H_2S , dissolving the product in aqueous NaOH , shaking with EtBr , and oxidising the product with KMnO_4 (Baumann, *B.* 23, 1875). Sparingly soluble colourless plates.

METHYLENE-FURFURANE TRIHYDRIDE

$\text{C}_3\text{H}_4\text{O}$ *i.e.* $\text{CH}_2\langle\text{CH}_2\text{C}(\text{CH}_2)\text{CH}_2\text{O}\rangle$. (111°) at 718 mm

Formed by the action of solid KOH on methyl bromo-propyl ketone (Lipp, *B.* 22, 1207). Mobile liquid, m. sol. water. Yields a hydrazide. When heated with 5 p.c. HClAq at 100° it yields aceto-propyl alcohol (methyl oxypropyl ketone). Probably identical with trimethylenyl methyl ketone of Perkin, *jun.* (*B.* 17, 1440).

TRI-METHYLENE GLYCOL $\text{C}_3\text{H}_6\text{O}_3$ *i.e.* $\text{CH}_2(\text{CHOH})_2$. (214°). S.G. $\frac{3}{4}$ 1.0625 (*Z.*); $\frac{18}{19}$ 1.0536 (*F.*). C.E. (0° – 10°) .00060. S.V. 84 (Zander, *A.* 214, 178; Lossen, *A.* 254, 59). One of the products of the fermentation of glycerin by schizomycetes (Freund, *M.* 2, 636).

Formation.—1. By saponifying its diacetyl derivative with baryta-water (Reboul, *A. Ch.* [6] 14, 491).—2. By warming trimethylene bromide with moist Ag_2O (Beilstein a. Wiegand, *B.* 15,

1497).—3. By allowing $\text{CH}_2(\text{CH}_2\text{Br})_2$ to stand for some time with a large excess of water (Niederist, M. 8, 889).—4. By boiling trimethylene bromide with dilute aqueous K_2CO_3 (Z.).

Properties.—Viscid liquid, with sweet taste, miscible with water.

Reactions.—1. Fuming HClAq at 100° converts it into $\text{CH}_2(\text{CH}_2\text{Cl})_2$.—2. Trimethylene glycol (35 g.) heated with aldehyde (12 g.) at 100° yields the ethylidene derivative (v. *infra*).

Di-acetyl derivative $\text{CH}_2(\text{CH}_2\text{OAc})_2$. (210° cor.). (c. 111°). S.G. $\frac{2}{25}$.991; $\frac{15}{15}$ 1.070. S. 11. Formed by boiling $\text{CH}_2(\text{CH}_2\text{Br})_2$ with NaOAc (Reboul).

Ethylidene derivative $\text{C}_4\text{H}_8\text{O}_2$ i.e. $\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix}\rangle\text{CH}_2\text{CH}_3$. V.D. 3.62 (calc. 3.53).

Obtained by heating the glycol with aldehyde at 100° , the yield being nearly the theoretical (Loohert, A. Ch. [6] 16, 49): Colourless liquid, with slight aldehydic odour. Dissolves in $1\frac{1}{2}$ volumes of water, v. sol. alcohol and ether. Separated from its aqueous solution by CaCl_2 and by KOH . Saponified by boiling water, alkalis, and dilute acids. With PCl_5 it yields aldehyde and $\text{CH}_2(\text{CH}_2\text{Cl})_2$.

Amylidene derivative $\text{C}_6\text{H}_{10}\text{O}_2$ i.e. $\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix}\rangle\text{CH}_2\text{C}_4\text{H}_9$. (c. 165°). S.G. $\frac{2}{25}$.995.

V.D. 5.03 (calc. 4.98). Formed by heating trimethylene glycol (35 g.) with valeric aldehyde (20 g.) in a sealed tube at 125° . Colourless mobile liquid, v. sl. sol. water, v. sol. alcohol and ether. Saponified by boiling water.

Heptylidene derivative $\text{C}_8\text{H}_{16}\text{O}_2$ i.e. $\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2\text{O} \\ \text{CH}_2\text{O} \end{smallmatrix}\rangle\text{CH}_2\text{C}_6\text{H}_{13}$. (c. 216°). S.G. $\frac{2}{25}$.933.

From the glycol (30 g.) and heptoic aldehyde (enanthal) at 160° (L.).

Bromhydrin v. Bromo-propyl alcohol.

TRI-METHYLENE-IMINE $\text{C}_3\text{H}_5\text{N}$ i.e.

$\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix}\rangle\text{NII}$. (65° – 80°). Formed, together

with a polymeride $\text{C}_6\text{H}_{11}\text{N}_2$ (160° – 167°), from $\text{CH}_2\text{Br}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NH}_2$ and NaOH in the cold (Gabriel a. Weiner, B. 21, 2669). Volatile liquid, smelling like NH_3 and fuming in the air. Eagerly combines with CS_2 .— $\text{B}^*\text{H}\text{AuCl}_4$.— $\text{B}^*\text{H}_2\text{PtCl}_6$.— $\text{B}^*\text{C}_6\text{H}_5(\text{NO}_2)\text{OH}$. [167°].

METHYLENE IODIDE CH_2I_2 . *Di-iodo-methane*. [4°]. (152° at 330 mm.). S.G. $\frac{4}{4}$ 3.2853; $\frac{25}{25}$ 3.2656. M.M. 18.827 at 15° (Perkin, C. J. 45, 464).

Formation.—1. By heating iodoform (4 mols.) with NaOEt (9 mols.) dissolved in alcohol (Butlerow, A. 107, 110; 111, 242; cf. Brüning, A. 104, 187).—2. By heating chloroform with HIAq at 130° (Blijducho, Z. [2] 7, 91).—3. By heating iodoform (50 g.) with conc. HIAq (200 g.) to boiling (127°) and adding phosphorus (Lieben, Z. 1868, 712; Baeyer, B. 5, 1035).—4. From methylene chloride and CaI_2 at 75° (Spindler, A. 281, 262).—5. By warming a mixture of iodoform (5 pts.), water (2 pts.) and reduced iron (5 pts.), and fractionally distilling *in vacuo* (Cazenouve, C. R. 98, 369).—6. An alcoholic solution of iodoform is decomposed by light, yielding CH_2I_2 and iodine. Oxalic acid accelerates the reaction (Mulder, R. T. C. 7, 816).

Properties.—Yellowish liquid, boiling with partial decomposition at 180° .

Reactions.—1. *Potassium* has no action in the cold, but on heating it acts with explosive violence.—2. Heated with *copper* and water, the products are cuprous iodide and a mixture of CO_2 , methane, CO , and ethylene (Butlerow, A. 120, 356).—3. *Silver acetate* forms the diacetyl derivative of formic orthaldehyde $\text{CH}_2(\text{OAc})_2$.—4. *Silver oxalate* yields formic paraldehyde (trioxymethylene).—5. *Chlorine* yields CH_2Cl_2 .—6. *Bromine* forms CH_2Br_2 (Arnhold, A. 240, 207).—7. Converted by PCl_5 at 70° into methylene chloride and a trace of chloroform (Höland, A. 240, 227).—8. Alcoholic Na_2S yields thioformic aldehyde.—9. NMe_3 combines with formation of $(\text{CH}_2\text{I})\text{NMe}_3\text{I}$.—10. *Aniline* forms $\text{CH}_2(\text{NHPh})_2$.—11. *Mercury* forms $\text{IHg}\cdot\text{CH}_2\text{I}$ (Sakurai, C. J. 37, 658).

Trimethylene iodide v. Di-iodo-propane.

DI-TETRAMETHYLENE KETONE v. Di-tetramethylenyl ketone.

METHYLENE-MALONIC ETHER $\text{C}_6\text{H}_{12}\text{O}_4$ i.e. $\text{CH}_2\cdot\text{C}(\text{CO}_2\text{Et})_2$. [156°]. Formed by heating malonic ether with methylene iodide and NaOEt (Zelinsky, B. 22, 3294). Mobile liquid. Isomeric with fumaric and maleic ethers. With bromine it yields $\text{CH}_2\text{Br}\cdot\text{CBr}(\text{CO}_2\text{Et})_2$ (185° – 190° at 75–85 mm.).

Polymeride $\{\text{CH}_2\cdot\text{C}(\text{CO}_2\text{Et})_2\}_n$. [156°]. Accompanies the preceding (Z.). Minute amorphous granules; insol. water, m. sol. ether and alcohol. Its molecular weight determined by Raoult's method is 342 (calc. 344).

DI-METHYLENE-DI-METHYL-DIAMINE $\text{C}_4\text{H}_{10}\text{N}_2$ i.e. $(\text{CH}_2)_2\text{N}_2\text{Me}_2$. V.D. ($\text{H}=1$) 41.5 (calc. 43). Formed by passing a mixture of trimethylamine and hydrogen through a red-hot tube (Romeny, B. 11, 835). Crystalline. Hot dilute HClAq splits it up into formic aldehyde and methylamine.— $\text{B}^*\text{H}\cdot\text{PtCl}_6$.

A base, boiling at about 207° , formed by the action of methylamine upon trioxymethylene (formic paraldehyde) is perhaps identical with the preceding (Kolotoff, B. [2] 45, 253).

TRIMETHYLENE-HEXA-METHYL-DIAMINE $(\text{C}_2\text{H}_5)_6\text{N}_4(\text{CH}_3)_6$. Formed by heating trimethylene bromide $(\text{C}_2\text{H}_5\text{Br})_3$ with trimethylamine.

Salts.— $\text{B}^*\text{H}\cdot\text{Br}$, aq: soluble colourless needles.— $\text{B}^*\text{H}_2\text{Cl}_2\cdot\text{PtCl}_6$: sparingly soluble (Roth, B. 14, 1351).

METHYLENE METHYL BUTENYL DIKETONE $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{C}_4\text{H}_9$. *Acetyl-mesityl oxide. Acetyl-angelicyl-methane*. (205°).

Formed as a secondary product in the preparation of methylenedimethyl diketone by the action of acetone and NaOEt on acetic ether (Claisen a. Ehrhardt, B. 22, 1012; B. [3] 1, 498). Oil, soluble in aqueous alkalis. Its alcoholic solution gives a red colour with FeCl_3 . Cupric acetate in concentrated solutions gives a dark-green pp.— CuA^+ . [123°]. Crystalline, v. sol. warm alcohol and ether.

METHYLENE DIMETHYL ETHER v. Dimethyl ether of Ortho-Formic aldehyde.

METHYLENE METHYL ETHYL DIKETONE $\text{C}_6\text{H}_{10}\text{O}_4$ i.e. $\text{C}_2\text{H}_5\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}_3$. *Acetyl-propionyl-methane*. (158°). S.G. $\frac{15}{15}$.9538. Formed by the action of EtOAc and NaOAc upon methyl ethyl ketone (Claisen a. Ehrhardt, B. 22, 1014).— $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2$. [179°]. Slender blue needles (from hot alcohol).

METHYLENE METHYL HEXYL DIKETONE $C_{15}H_{28}O_2$, i.e. $CH_3.CO.CH_2.CO.C_6H_{13}$, (229°). Formed from methyl hexyl ketone, AcOEt, and AcONa (Claisen a. Ehrhardt, *B.* 22, 1015). Liquid.— $Cu(C_{10}H_{17}O_2)_2$, [122°]. Crystalline.

METHYLENE DI-METHYL DIKETONE $C_5H_8O_2$, i.e. $CH_3(CO.CH_2)_2$. *Di-acetyl-methane*. *Acetyl-acetone*. (136°). S.G. 1.987 (Combes).

Preparation.—1. By slowly adding acetone (1 mol.) to a mixture of acetic ether ($3\frac{1}{2}$ mols.) and dry NaOEt (1 mol.) heated on the water-bath. The product is poured into ice-cold water, and the aqueous liquid mixed with HOAc and cupric acetate, which ppts. $Cu(C_2H_3O_2)_2$. The yield is 35 p.c. of the weight of acetone employed (Claisen, *Bl.* [3] 1, 498).—2. Acetone (5.8 pts.) mixed with EtOAc (33 pts.) is treated in the cold with sodium-wire (2.3 pts.). When most of the sodium is dissolved, the mixture is heated on a water-bath. The product is pptd. as cupric salt, the yield of ketone being 55 p.c. of the acetone employed (Claisen a. Ehrhardt, *B.* 22, 1009). In either case the diketone is obtained from the copper compound by adding dilute H_2SO_4 and extracting with ether.—3. From the compound $C_2H_5O_2AlCl_2$ (obtained from acetyl chloride and $AlCl_3$) by adding water and extracting with chloroform. The yield is 85 p.c. of the theoretical (Combes, *A. Ch.* [6] 12, 211).

Properties.—Colourless liquid with pleasant acetic odour, sol. water, v. sol. aqueous HCl, miscible with alcohol, ether, and chloroform. Not attacked by PCl_5 .

Reactions.—1. *Phenyl-hydrazine* forms phenyl-dimethyl-pyrazole $CH<NPh.N>CHMe$ (270.5°) (Combes, *Bl.* [2] 50, 145).—2. *Potash* decomposes it into acetone and KOAc.—3. PCl_5 yields HCl and $C_2H_5Cl_2$ (145°), a di-chloro-amine which readily combines with bromine.—4. *Sodium-amalgam* yields isopropyl alcohol and pinacene. But in acid solution the products of reduction by sodium-amalgam are di-oxy-pentane $CH_2CH(OH).CH_2CH(OH).CH_3$, and a tetra-hyric alcohol analogous to pinacene.—5. Conc. $HIAq$ at 185° reduces it to pure *n*-pentane (38°). At lower temperatures it forms $CH_2(CHI.CH_2)_2$ and $CH_2CHI.CH_2CH_2CH_3$.—6. Excess of *chlorine* in sunlight yields $(COCl_2.CO)_2CH_2$ as final product.—7. *Bromine* attacks the diketone vigorously, finally producing $(CBr_2.CO)_2CH_2$ [108°].—8. *Oxidation* by CrO_3 or by $KMnO_4$ yields acetic acid.—9. Warm dilute *nitric acid* produces $CH_3(NO_2)_2$ and HOAc.—10. Dry *ammonia* passed into its ethereal solution ppts. white pearly scales of the ammonium salt $CH(NH_2)(CO.CH_3)_2$.—11. *Ethylene-diamine* (2 mols.) forms $C_2H_4(N.CMe.CH_2Ac)_2$ [111°] which yields a violet cupric salt $C_2H_4N_2O_4Cu$ [197°] and a hydrochloride $C_2H_4N_2O_4HCl$ melting above 280°. Other diamines act in like manner (Combes, *C. R.* 108, 1252).—12. Unites with *benzidine* (1 mol.) forming a base melting at 195° (Combes).—13. *Aldehyde-ammonia* ($\frac{1}{2}$ mol.) at 100° forms di-acetyl-tri-methyl-pyridine di-hydrate $C_5H_7NO_2$ [153°] (Combes, *Bl.* [3] 1, 14).—14. Toluene-*m*-diamine at 100°, followed by H_2SO_4 , yields amido-trimethyl-quinoline $C_9H_9N_2$ [191°] (Combes, *C. R.* 108, 1254).—15. SO_2Cl_2 forms the chloro-derivative $C_5H_7ClO_2$ (150°) (Combes, *C. R.* 111, 272).

Salts.— $CH(NH_2)(CO.CH_3)_2$. Pearly scales, pptd. by passing NH_3 into the ethereal solution. Decomposes readily into acetone and acetamide. — $Ac.CHNa$. Formed by dissolving sodium in the diketone (Combes, *C. R.* 104, 920). White six-sided prisms, insol. ether. Decomposed by water into acetone and NaOAc. With ethyl iodide at 140° it gives $CHEt(CO.CH_3)_2$, a liquid boiling at 171°. Amyl iodide, in like manner, yields $C_5H_{11}CH(CO.CH_3)_2$. The second atom of hydrogen in the methylene group may, in such compounds, be displaced by Na, and by acting with an alkyl iodide RI upon $RCNa(CO.CH_3)_2$, we may obtain compounds of the form $RCR'(CO.CH_3)_2$. These reactions take place with hardly any secondary decompositions. These homologues of methylene dimethyl diketone are decomposed by potash like the diketone itself (Combes, *A. Ch.* [6] 12, 211). $ClCO_2Et$ acting on the sodium derivative of methylene dimethyl diketone forms $C(COMe)_2(CO_2Et)_2$ (Claisen a. Zedel, *B.* 21, 3397).— $KCHAc$. White six-sided prisms, sl. sol. alcohol, insol. ether. Formed by adding KOEt to an alcoholic solution of the diketone. Decomposed by hot water into acetone and KOAc.— $Mg(CHAc)_2$ (dried at 125°). From the diketone and magnesium carbonate (Combes, *C. R.* 105, 868). Transparent six-sided prisms.— $Al(CHAc)_3$. A by-product in the rectification of the diketone, from which it may be obtained by treatment with $AlCl_3$. Small red crystals, insol. water, sl. sol. alcohol, v. sl. sol. ether. Can be partially volatilised. Acts on polarised light. Not decomposed by alcoholic NH_3 .— $Cu(HCAc)_2$ (dried at 125°). Pale-blue needles, obtained by adding cupric acetate or chloride to an aqueous solution of the diketone. Insol. water, the p.pn. being complete in dilute solutions. At 65° it forms with $COCl_2$ dissolved in benzene a crystalline compound melting at 121° (Thomas a. Lefèvre, *Bl.* [2] 50, 193).— $Fe(HCAc)_3$. Red crystals, deposited from the ethereal extract of the red solution obtained by adding $FeCl_3$ to the diketone dissolved in water.— $Pb(HCAc)_2$. From the diketone and lead carbonate. Transparent crystals, sol. water.

Oxim $CH_3.CO.CH_2.C(NOH).CH_3$. Anhydride $CH<CMe.O>CMe:N$. (142°). S.G. 1.985.

Formed by the action of hydroxylamine on the diketone (Zedel, *B.* 21, 2178). Colourless oil, with peculiar alkaloidal odour.

Di-oxim $CH_3C(NOH).CH_3$. [150°]. Large transparent crystals (from ether).

Phenyl-methyl-hydrazide $CH_3.CO.CH_2.C(NPhMe).CH_3$ (Kohlrausch, *A.* 253, 22).

Di-methylene di-methyl triketone $(CH_3.CO.CH_2)_2CO$. *Di-acetyl-acetone*. [49°]. Formed from its anhydride (*v. infra*). Plates. Sl. sol. water, sol. alkalis, warm alcohol, and ether. $FeCl_3$ gives a deep-red colour. Converted by NH_3 into oxy-di-methyl-pyridine [225°].

Anhydride $CO<CH:O>CMe$. *Di-methyl-pyrone*. [132°]. (249°). Formed by the action of $HIAq$ on dehydracetic acid at a high temperature (Feist, *B.* 22, 1570; *A.* 257, 258). The yield is 70 p.c. of the theoretical. Crystals, v. e. sol. water. Converted by baryta, followed by HCl, into di-methylene di-methyl tri-ketone. The carboxylic

acid of this anhydride is dehydracetic acid. The dicarboxylic ether $\text{CO} \begin{smallmatrix} \text{C}(\text{CO}_2\text{Et})\text{CMe} \\ \text{C}(\text{CO}_2\text{Et})\text{CMe} \end{smallmatrix} \text{O}$ [80°].

S. 8 at 20° is formed by the action of COCl_2 on copper acetoacetic ether, and is converted by P_2S_5 into $\text{CS} \begin{smallmatrix} \text{C}(\text{CO}_2\text{Et})\text{CMe} \\ \text{C}(\text{CO}_2\text{Et})\text{CMe} \end{smallmatrix} \text{O}$ [110°] (Conrad, B. 19, 22; 20, 152; 2111).

Di-phenyl-hydrazide
($\text{CH}_3\text{C}(\text{N}(\text{HPh})\text{CH}_3)_2\text{CO}$). [142°].

Trimethylene methyl ketone v. TRIMETHYLENETHYL METHYL KETONE.

Tetramethylene methyl ketone v. TETRAMETHYLENETHYL METHYL KETONE.

METHYLENE DIMETHYL ETHER v. Methyl-ether of FORMIC ORTHALDEHYDE.

METHYLENE DIMETHYL DIOXIDE v. Methyl ether of FORMIC ORTHALDEHYDE, vol. ii. p. 570.

METHYLENE METHYL PHENYL DIKETONE v. BENZOYL-ACETONE.

METHYLENE-METHYL-PHTHALIMIDINE

$\text{C}_{10}\text{H}_8\text{ON}$ i.e. $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}=\text{CH}_2 \\ >\text{NMe} \end{smallmatrix} \text{CO}$. Formed by heating phthal-methyl-imidyl-acetic acid

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CC}=\text{H.CO}_2\text{H} \\ >\text{NMe} \end{smallmatrix} \text{CO}$ above 210°. Colourless crystals. Volatile with steam. V. sol. alcohol, ether, and chloroform, more sparingly sol. water. Very unstable body (Gabriel, B. 18, 2454).

METHYLENE METHYL PROPYL DIKETONE $\text{C}_9\text{H}_{10}\text{O}_2$ i.e. $\text{CH}_3\text{CO.CH}_2\text{CO.C}_2\text{H}_5$, (175°). S.G. 15.9411. Formed by the action of EtOAc and NaOAc upon methyl propyl ketone (Chaisen a. Ehrhardt, B. 22, 1015). Formed also from butyric ether, acetone, and NaOEt . Colourless oil. Boiling alkalis yield acetic and butyric acids. Yields $\text{C}_6\text{H}_5\text{N}_2\text{CHAc.COPr}$ [55°] crystallising in yellow prisms.— $\text{Cu}(\text{C}_6\text{H}_4\text{O}_2)_2$ [161°]. Blue needles.

TETRA-METHYL-TRIMETHYLENE-DI-

PYRROLE $\text{C}_{13}\text{H}_{22}\text{N}_2$ i.e. $\left(\begin{smallmatrix} \text{CH}_2\text{CMe} \\ | \\ \text{CH}_2\text{CMe} \end{smallmatrix} \right)_2\text{N.CH}_2$, [77°]. Formed by heating acetonyl-acetone with alcoholic tri-methylene-diamine at 120° (Paal a. Schneider, B. 19, 3157). Crystalline.

METHYLENE DI-METHYL DISULPHONE $(\text{CH}_3\text{SO}_2)_2\text{CH}_2$. [141°]. Formed from methyl mercaptan and methylene chloride, and oxidation of the product (Baumann, B. 23, 1875). Plates. On treatment with bromine-water it gives $\text{CBr}_2(\text{SO}_2\text{Me})_2$ [234°].

Di-methylene di-methyl trisulphone $(\text{CH}_3\text{SO}_2\text{CH}_2)_2\text{SO}_2$. [185°]. Formed by saturating a solution of formic aldehyde with H_2S , extracting with ether, evaporating, dissolving the residual oil in aqueous NaOH , adding MeI , and oxidising with KMnO_4 (Baumann, B. 23, 1872). Prisms, v. sl. sol. cold water, alcohol, and ether. Yields with bromine-water insoluble $\text{C}_6\text{H}_5\text{Br.S}_2\text{O}_3$ [190°].

TRIMETHYLENE TRINITROSAMINE $\text{C}_3\text{H}_5\text{N}_3\text{O}$ i.e. $(\text{CH}_2\text{N.NO})_3$. [106°]. Formed by the action of nitrous acid upon hexamethylene-amine (F. Mayer, B. 21, 2883). Yellow needles or prisms (from alcohol); v. sol. alcohol, insol.

petroleum-ether. Decomposed by water with production of formic aldehyde.

METHYLENE DI-OCTYL OXIDE v. Octyl ether of FORMIC ORTHALDEHYDE.

METHYLENE OXIDE is FORMIC ALDEHYDE (q. v.).

METHYLENE-DI-OXY compounds v. Methylene derivatives of DI-OXY compounds.

METHYLENE-DI-PHENYL-DIAMINE v. DI-PHENYL-METHYLENE-DIAMINE.

METHYLENE-DI-PHENYLENE v. DI-PHENYLENE-METHANE.

METHYLENE-DIPHENYLENE OXIDE v. DI-PHENYLENE-METHANE OXIDE.

METHYLENE DIPHENYL DIKETONE v. DI-PHENYL METHYLENE DIKETONE.

TRIMETHYLENE PHENYL KETONE v. PHENYL TRIMETHYLENE KETONE.

Tetramethylene phenyl ketone v. Anhydride of PHENYL OXYBUTYL KETONE.

METHYLENE-DIPHENYL OXIDE v. DI-PHENYLENE-METHANE OXIDE.

METHYLENE HEXAPHENYL PHOSPHONIUM IODIDE v. Methylene-di-iodide of TRI-PHENYL-PHOSPHINE.

TRIMETHYLENE-DI-PHTHALAMIC ACID $\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_4$ i.e. $\text{CH}_2(\text{CH}_2\text{NH.CO.C}_6\text{H}_4\text{CO}_2\text{H})_2$. [70°-123°]. Obtained by boiling trimethylene di-phthalimide with potash (Gabriel, B. 21, 2670). Crystalline. Decomposed by water. On boiling with aqueous HCl it is converted into phthalic acid and trimethylene-diamine.

METHYLENE-PHTHALIDE $\text{C}_8\text{H}_6\text{O}_2$ i.e. $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}=\text{CH}_2 \\ >\text{O} \\ \text{C}=\text{O} \end{smallmatrix}$. Anhydride of o-Oxy-vinylbenzoic acid. [60°]. Formed by heating phthalyl-acetic acid in vacuo (Gabriel, B. 17, 2521). Small glistening crystals. Soluble in hot water, easily in alcohol, ether, benzene, &c. Volatile with steam. It readily polymerises. Combines with Br (1 mol.).

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}=\text{CH}_2 \\ >\text{O} \\ \text{C}=\text{O} \end{smallmatrix}$. [99°]. Thick glistening crystals. Formed by the combination of methylene-phthalide with bromine. On warming with aqueous KOH it yields aceto-phenone-o-carboxylic acid $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{CO.CH}_3$. Boiled with water it gives methylene-phthalide-oxide $\text{C}_8\text{H}_6\text{O}_3$ (Gabriel, B. 17, 2524).

Methylene-phthalide-oxide $\text{C}_8\text{H}_6\text{O}_3$. [146°]. Long needles. Formed by boiling the dibromide of methylene-phthalide with water. Formed also by the action of water on the product of the bromination of acetophenone-o-carboxylic acid (Gabriel, B. 17, 2524).

Di-chloro-methylene-phthalide $\text{C}_8\text{H}_4\text{Cl}_2\text{O}_2$ i.e. $\text{C}_6\text{H}_2 \begin{smallmatrix} \text{C}=\text{COCl}_2 \\ >\text{O} \\ \text{C}=\text{O} \end{smallmatrix}$. [128°]. Formed by passing

chlorine into a mixture of a-chloro-phenyl-acetic acid (1 pt.) and HOAc (10 pts.). Formed also by warming di-chloro-acetophenone carboxylic acid with conc. H_2SO_4 (Zincke a. Cooksey, A. 255, 383). Long slender needles, gradually becoming compact when left in the liquid. The needles are v. sol. hot alcohol, benzene, HOAc , and benzoline, the compact crystals are soluble with difficulty. Alcoholic potash

converts it into di-chloro-acetophenone-o-carboxylic acid. Forms a dichloride

which crystallises in colourless prisms [94°], v. sol. alcohol and HOAc, and converted by alcoholic potash into phthalic acid.

Bromo-methylene-phthalide v. vol. i. p. 380.

Isomeride of methylene phthalide v. METHYLENE-PHTHALYL.

Polymeride of methylene-phthalide $\text{C}_{12}\text{H}_8\text{O}_4$. [216°]. Obtained by allowing a solution of acetophenone carboxylic acid (1 pt.) in H_2SO_4 (2 pts.) to stand in the cold, and then ppg. with water (Roser, B. 17, 2620; Gabriel, B. 17, 2666; cf. ACETOPHENONE O-CARBOXYLIC ACID, reaction 2). Plates. Insol. water and cold alkalis, sl. sol. alcohol, v. sol. HOAc.

Oxim $\text{C}_{12}\text{H}_{11}\text{NO}_4$. [180°]. Obtained by heating the substance with alcoholic hydroxylaminehydrochloride at 160°. Crystalline granules (from dilute HOAc).

METHYLENE-DI-PHTHALIMIDE

$\text{CH}_2(\text{N} \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{C}_6\text{H}_4)_2$. [226°]. Formed by heating potassium phthalimide (2 mols.) with methylene iodide (1 mol.) at 175° (Neumann, B. 23, 1002). Light-brown crystals (from HOAc); insol. dilute alkalis. Yields phthalic acid on heating with HClAq.

TRIMETHYLENE-DI-PHTHALIMIDE

$\text{C}_6\text{H}_4\text{N}_2\text{O}_4$, i.e. $\text{C}_6\text{H}_4\text{O}_2\text{N} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{N} \cdot \text{C}_6\text{H}_4\text{O}_2$. [198°]. Formed by the action of tri-methylene bromide on potassium phthalimide (Gabriel, B. 21, 2669). White needles; m. sol. hot HOAc, sl. sol. ether, CS_2 , chloroform, and cold alcohol, v. sl. sol. water and petroleum ether. Converted by heating with KOH into tri-methylene-diphthalamic acid $\text{C}_6\text{H}_4(\text{NHCOOC}_6\text{H}_4\text{CO}_2\text{H})_2$. Decomposed by heating with HCl at 180° into phthalic acid and tri-methylene-diamine.

METHYLENE-PHTHALYL $\text{C}_8\text{H}_4\text{O}_2$, i.e.

$\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{CH}_2$. [219°]. Fine yellow needles.

Formed, together with o-tribenzoylene-benzene, by heating phthalic anhydride with malonic ether and sodium acetate (Gabriel, B. 14, 925).

METHYLENE-DI-PIPERIDINE
